[Tutorials](#)

[Analysis Services tutorials overview](#)

[Tabular models](#)

[Internet Sales tutorial \(1400\)](#)

[Internet Sales tutorial overview \(1400\)](#)

[1 - Create a tabular model project](#)

[2 - Get data](#)

[3 - Mark as Date Table](#)

[4 - Create relationships](#)

[5 - Create calculated columns](#)

[6 - Create measures](#)

[7 - Create Key Performance Indicators](#)

[8 - Create perspectives](#)

[9 - Create hierarchies](#)

[10 - Create partitions](#)

[11 - Create roles](#)

[12 - Analyze in Excel](#)

[13 - Deploy](#)

[Supplemental lesson - Detail Rows](#)

[Supplemental lesson - Dynamic security](#)

[Supplemental lesson - Ragged hierarchies](#)

[Internet Sales tutorial \(1200\)](#)

[Internet Sales tutorial overview \(1200\)](#)

[1 - Create a New Tabular Model Project](#)

[2 - Add Data](#)

[3 - Mark as Date Table](#)

[4 - Create relationships](#)

[5 - Create calculated columns](#)

[6 - Create measures](#)

[7 - Create Key Performance Indicators](#)

[8 - Create perspectives](#)

[9 - Create hierarchies](#)

[10 - Create partitions](#)

[11 - Create roles](#)

[12 - Analyze in Excel](#)

[13 - Deploy](#)

[Supplemental Lesson - Implement dynamic security by using row filters](#)

[Multidimensional models](#)

[Adventure works tutorial](#)

[Tutorial scenario](#)

[Install sample data and projects for the Analysis Services Multidimensional modeling tutorial](#)

[Lesson 1 - Defining a data source view within an Analysis Services project](#)

[Lesson 1-1 - Creating an Analysis Services project](#)

[Lesson 1-2 - Defining a data source](#)

Lesson 1-3 - Defining a data source view

Lesson 1-4 - Modifying default table names

Lesson 2 - Defining and deploying a cube

Lesson 2-1 - Defining a dimension

Lesson 2-2 - Defining a cube

Lesson 2-3 - Adding attributes to dimensions

Lesson 2-4 - Reviewing cube and dimension properties

Lesson 2-5 - Deploying an Analysis Services project

Lesson 2-6 - Browsing the cube

Lesson 3 - Modifying measures, attributes and hierarchies

Lesson 3-1 - Modifying measures

Lesson 3-2 - Modifying the customer dimension

Lesson 3-3 - Modifying the product dimension

Lesson 3-4 - Modifying the date dimension

Lesson 3-5 - Browsing the deployed cube

Lesson 4 - Defining advanced attribute and dimension properties

Lesson 4-1 - Using a modified version of the Analysis Services tutorial project

Lesson 4-2 - Defining parent attribute properties in a parent-child hierarchy

Lesson 4-3 - Automatically grouping attribute members

Lesson 4-4 - Hiding and disabling attribute hierarchies

Lesson 4-5 - Sorting attribute members based on a secondary attribute

Lesson 4-6 - Specifying attribute relationships between attributes in a user-defined hierarchy

Lesson 4-7 - Defining the unknown member and null processing properties

Lesson 5 - Defining relationships between dimensions and measure groups

Lesson 5-1 - Defining a referenced relationship

Lesson 5-2 - Defining a fact relationship

Lesson 5-3 - Defining a many-to-many relationship

Lesson 5-4 - Defining dimension granularity within a measure group

Lesson 6 - Defining calculations

Lesson 6-1 - Defining calculated members

Lesson 6-2 - Defining named sets

Lesson 7 - Defining Key Performance Indicators (KPIs)

- [Lesson 7-1 - Defining and browsing KPIs](#)
- [Lesson 8 - Defining actions](#)
 - [Lesson 8-1 - Defining and using a drillthrough action](#)
- [Lesson 9 - Defining perspectives and translations](#)
 - [Lesson 9-1 - Defining and browsing perspectives](#)
 - [Lesson 9-2 - Defining and browsing translations](#)
- [Lesson 10 - Defining administrative roles](#)
 - [Lesson 10 - Granting process database permissions](#)
- [Data Mining](#)
- [How-to](#)
 - [Install and configure](#)
 - [Install SQL Server Analysis Services](#)
 - [Install Analysis Services in Power Pivot Mode](#)
 - [Install an Analysis Services server in Power Pivot Mode](#)
 - [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2016\)](#)
 - [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)
 - [Configure Power Pivot and Deploy Solutions \(SharePoint 2016\)](#)
 - [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#)
 - [Configure Analysis Services and Kerberos Constrained Delegation \(KCD\)](#)
 - [Verify a Power Pivot for SharePoint installation](#)
 - [Use PowerShell to Verify Power Pivot for SharePoint](#)
 - [Verify cumulative update build version](#)
 - [Post-install configuration](#)
 - [Post install and configuration overview](#)
 - [Configure the Windows Firewall](#)
 - [Configure the service account](#)
 - [Add administrators](#)
 - [Features off by default](#)
 - [Server groups in SSMS](#)
 - [Determine the Server Mode](#)
 - [Rename an Analysis Services instance](#)
 - [Tabular modeling](#)

What is Analysis Services?

9/5/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Analysis Services is an analytical data engine (Vertipaq) used in decision support and business analytics. It provides enterprise-grade semantic data models for business reports and client applications such as Power BI, Excel, Reporting Services reports, and other data visualization tools. Analysis Services is available in different platforms:

SQL Server Analysis Services - Installed as an on-premises server instance, SQL Server Analysis Services supports tabular models at all compatibility levels (depending on version), multidimensional models, data mining, and Power Pivot for SharePoint.

Azure Analysis Services - Created as an Azure resource, Azure Analysis Services server resources support tabular models at the 1200 and higher compatibility levels. DirectQuery, partitions, row-level security, bi-directional relationships, and translations are all supported.

Power BI Premium (Preview) - The Analysis Services Vertipaq engine provides programmability, client application, and tool support for Power BI Premium datasets through client libraries and APIs that support the open-standard XMLA protocol. Currently, Power BI Premium datasets support connect and *read-only* operations from Microsoft and third-party [client applications and tools](#) through XMLA endpoints.

Documentation

Analysis Services documentation is located at different places in docs.microsoft.com depending on the platform or version you're using. In general, [Azure Analysis Services documentation](#) is included with Azure documentation. If you're interested in having your tabular models in the cloud, it's best to start there.

Documentation you see in the Table of Contents to the left is known as the core Analysis Services documentation. Core documentation can apply to just one platform, like SQL Server Analysis Services, or to all Analysis Services platforms including Azure Analysis Services. This is because how you create and deploy a tabular model, or manage certain server properties or databases is much the same, regardless of platform.

In the core documentation, at the top of each article an **Applies To** banner indicates the platforms the article applies to. Keep in mind, feature and functionality changes are happening to each platform all the time. When they do, we make every effort to update the documentation.

Looking for **SQL Server 2014 Analysis Services** documentation? - SQL Server 2014 Analysis Services documentation is kept separate from later version documentation. This is due to changing documentation models used on docs.microsoft.com compared to MSDN, where SQL Server 2014 and earlier Books Online documentation was originally published. Go to [SQL Server 2014 Analysis Services documentation](#). Need to go back even further? See [SQL Server previous versions documentation](#).

[What is Power BI Premium?](#)

What's New in SQL Server Analysis Services

11/8/2019 • 26 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

This article summarizes new features and improvements in the most recent versions of SQL Server Analysis Services (SSAS). New features and improvements are cumulative.

SQL Server 2019 Analysis Services

Tabular model compatibility level

This release introduces the 1500 [compatibility level](#) for tabular models.

Query interleaving

Query interleaving is a tabular mode system configuration that can improve user query response times in high-concurrency scenarios. Query interleaving with *short query bias* allows concurrent queries to share CPU resources. To learn more, see [Query interleaving](#).

Calculation groups in tabular models

Calculation groups can significantly reduce the number of redundant measures by grouping common measure expressions as *calculation items*. Calculation groups are shown in reporting clients as a table with a single column. Each value in the column represents a reusable calculation, or calculation item, that can be applied to any of the measures. A calculation group can have any number of calculation items. Each calculation item is defined by a DAX expression. To learn more, see [Calculation groups](#).

Governance setting for Power BI cache refreshes

The **ClientCacheRefreshPolicy** property setting is now supported in SSAS 2019 and later. This property setting is already available for Azure Analysis Services. The Power BI service caches dashboard tile data and report data for initial load of Live Connect report, causing an excessive number of cache queries being submitted to the engine, and in extreme cases overload the server. The **ClientCacheRefreshPolicy** property allows you to override this behavior at the server level. To learn more, see [General Properties](#).

Online attach

This feature provides the ability to attach a tabular model as an online operation. Online attach can be used for synchronization of read-only replicas in on-premises query scale-out environments. To perform an online-attach operation, use the **AllowOverwrite** option of the Attach XMLA command.

```
<Attach xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Folder>C:\Program Files\Microsoft SQL Server\MSAS15\OLAP\Data\AdventureWorks.0.db\</Folder>
  <AllowOverwrite>True</AllowOverwrite>
</Attach>
```

This operation may require *double the model memory* to keep the old version online while loading the new version.

A typical usage pattern could be as follows:

1. DB1 (version 1) is already attached on read-only server B.
2. DB1 (version 2) is processed on the write server A.

3. DB1 (version 2) is detached and placed on a location accessible to server B (either via a shared location, or using robocopy, etc.).
4. The command with AllowOverwrite=True is executed on server B with the new location of DB1 (version 2).

Without this feature, admins are first required to detach the database and then attach the new version of the database. This leads to downtime when the database is unavailable to users, and queries against it will fail.

When this new flag is specified, version 1 of the database is deleted atomically within the same transaction with no downtime. However, it comes at the cost of having both databases loaded into memory simultaneously.

Many-to-many relationships in tabular models

This improvement allows many-to-many relationships between tables where both columns are non-unique. A relationship can be defined between a dimension and fact table at a granularity higher than the key column of the dimension. This avoids having to normalize dimension tables and can improve the user experience because the resulting model has a smaller number of tables with logically grouped columns.

Many-to-many relationships require models be at the 1500 and higher compatibility level. You can create many-to-many relationships by using Visual Studio 2019 with Analysis Services projects VSIX update 2.9.2 and higher, the Tabular Object Model (TOM) API, Tabular Model Scripting Language (TMSL), and the open-source Tabular Editor tool.

Memory settings for resource governance

The following property settings provide improved resource governance:

- **Memory\QueryMemoryLimit** - This memory property can be used to limit memory spools built by DAX queries submitted to the model.
- **DbpropMsmdRequestMemoryLimit** - This XMLA property can be used to override the Memory\QueryMemoryLimit server property value for a connection.
- **OLAP\Query\RowsetSerializationLimit** - This server property limits the number of rows returned in a rowset, protecting server resources from extensive data export usage. This property applies to both DAX and MDX queries.

These properties can be set by using the latest version of SQL Server Management Studio (SSMS). These settings are already available for Azure Analysis Services.

SQL Server 2017 Analysis Services

SQL Server 2017 Analysis Services see some of the most important enhancements since SQL Server 2012. Building on the success of Tabular mode (first introduced in SQL Server 2012 Analysis Services), this release makes tabular models more powerful than ever.

Multidimensional mode and Power Pivot for SharePoint mode are a staple for many Analysis Services deployments. In the Analysis Services product lifecycle, these modes are mature. There are no new features for either of these modes in this release. However, bug fixes and performance improvements are included.

The features described here are included in SQL Server 2017 Analysis Services. But in order to take advantage of them, you must also use the latest versions of Visual Studio with Analysis Services projects and SQL Server Management Studio (SSMS). Analysis Services projects and SSMS are updated monthly with new and improved features that typically coincide with new functionality in SQL Server.

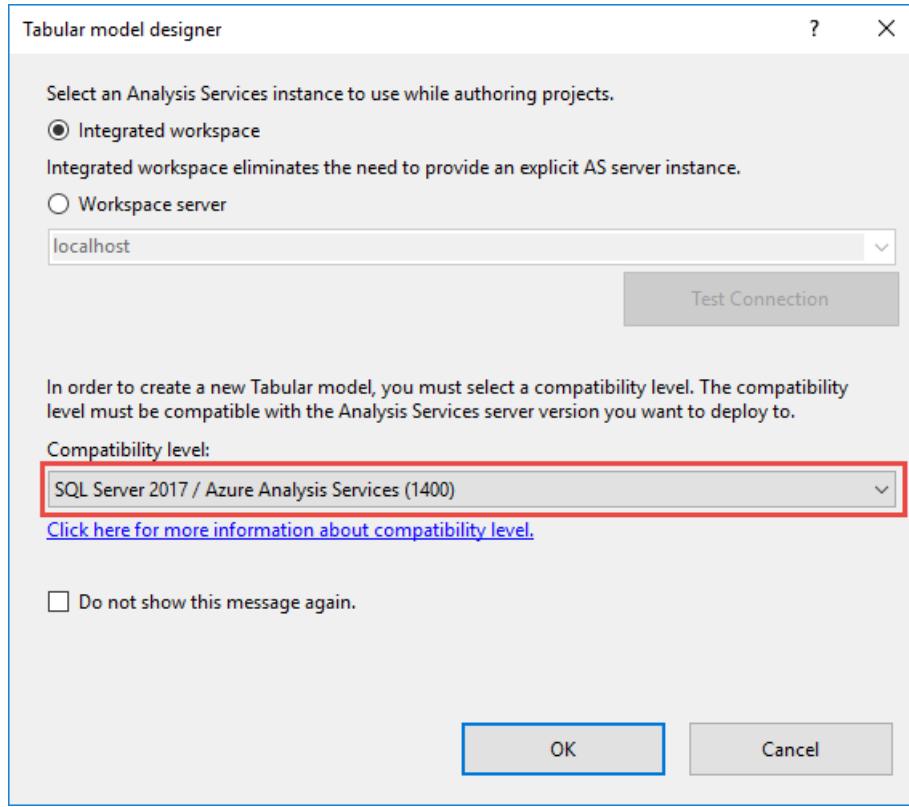

While it's important to learn about all the new features, it's also important to know what is being deprecated and discontinued in this release and future releases. Be sure to check out [Analysis Services backward compatibility](#).

Let's take a look at some of the key new features in this release.

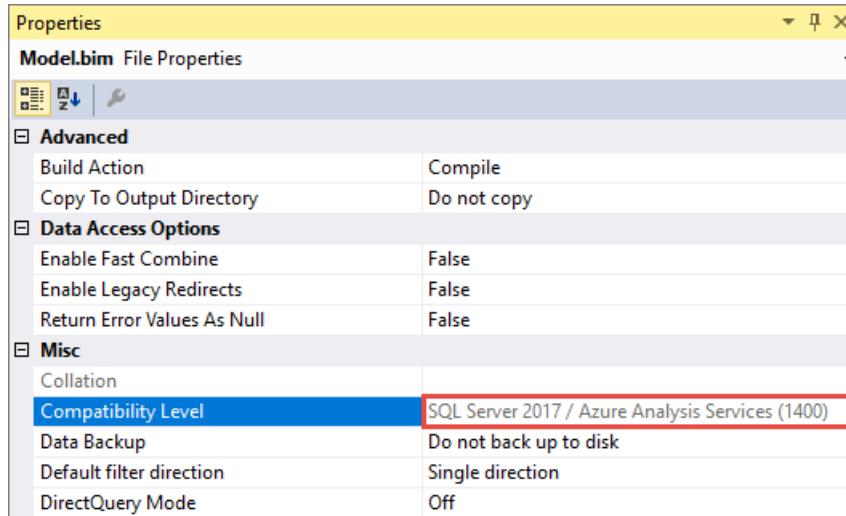

1400 Compatibility level for tabular models

To take advantage of many of the new features and functionality described here, new or existing tabular models must be set or upgraded to the 1400 compatibility level. Models at the 1400 compatibility level cannot be deployed to SQL Server 2016 SP1 or earlier, or downgraded to lower compatibility levels. To learn more, see [Compatibility level for Analysis Services tabular models](#).

In Visual Studio, you can select the new 1400 compatibility level when creating new tabular model projects.

To upgrade an existing tabular model in Visual Studio, in Solution Explorer, right-click **Model.bim**, and then in **Properties**, set the **Compatibility Level** property to **SQL Server 2017 (1400)**.

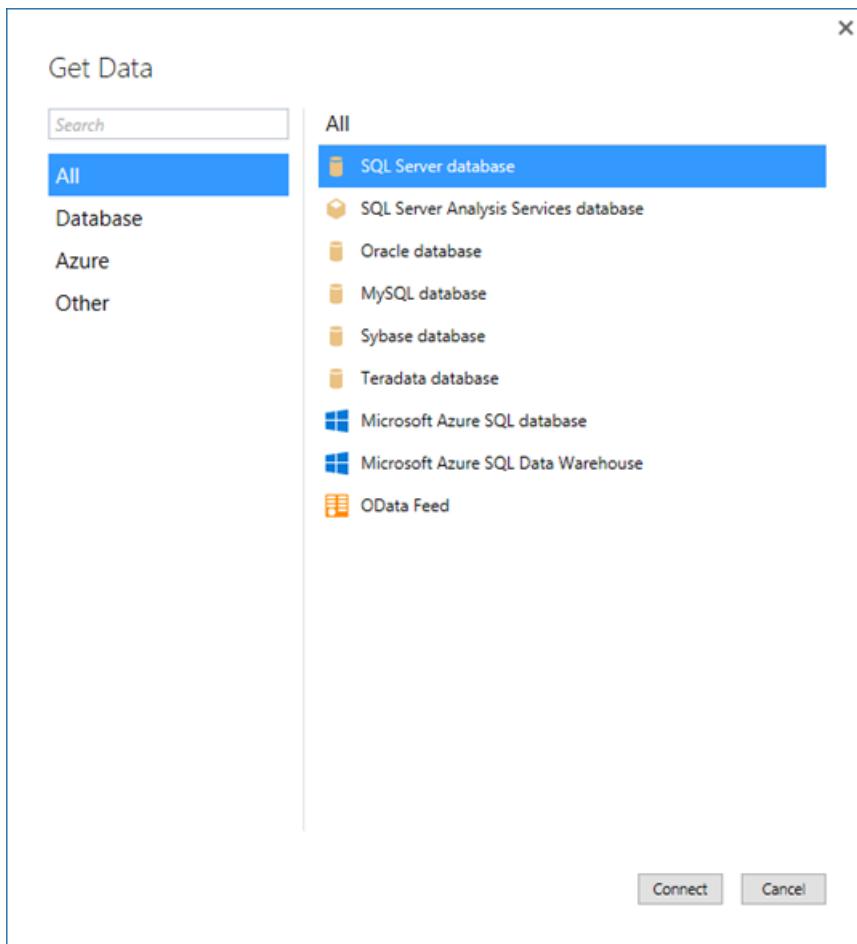

It's important to keep in mind, once you upgrade an existing model to 1400, you can't downgrade. Be sure to keep a backup of your 1200 model database.

Modern Get Data experience

When it comes to importing data from data sources into your tabular models, SSDT introduces the modern **Get Data** experience for models at the 1400 compatibility level. This new feature is based on similar functionality in Power BI Desktop and Microsoft Excel 2016. The modern Get Data experience provides immense data transformation and data mashup capabilities by using the Get Data query builder and M expressions.

The modern Get Data experience provides support for a wide range of data sources. Going forward, updates will include support for even more.

A powerful and intuitive user interface makes selecting your data and data transformation/mashup capabilities easier than ever.

```

let
    Source = "#"SQL/myserver;AdventureWorks",
    dbo_DimCustomer = Source{[Schema="dbo",Item="DimCustomer"]}[Data],
    #"Removed Columns" = Table.RemoveColumns(dbo_DimCustomer,{"GeographyKey"})
in
    #"Removed Columns"

```

✓ No syntax errors have been detected.

Done Cancel

31 COLUMNS, 999+ ROWS PREVIEW DOWNLOADED AT 2:00 PM

The modern Get Data experience and M mashup capabilities do not apply to existing tabular models upgraded from the 1200 compatibility level to 1400. The new experience only applies to new models created at the 1400 compatibility level.

Encoding hints

This release introduces encoding hints, an advanced feature used to optimize processing (data refresh) of large in-memory tabular models. To better understand encoding, see [Performance Tuning of Tabular Models in SQL Server 2012 Analysis Services](#) whitepaper to better understand encoding.

- Value encoding provides better query performance for columns that are typically only used for aggregations.
- Hash encoding is preferred for group-by columns (often dimension-table values) and foreign keys. String columns are always hash encoded.

Numeric columns can use either of these encoding methods. When Analysis Services starts processing a table, if either the table is empty (with or without partitions) or a full-table processing operation is being performed, samples values are taken for each numeric column to determine whether to apply value or hash encoding. By default, value encoding is chosen when the sample of distinct values in the column is large enough - otherwise hash encoding usually provides better compression. It is possible for Analysis Services to change the encoding method after the column is partially processed based on further information about the data distribution, and restart the encoding process; however, this increases processing time and is inefficient. The performance-tuning whitepaper discusses re-encoding in more detail and describes how to detect it using SQL Server Profiler.

Encoding hints allow the modeler to specify a preference for the encoding method given prior knowledge from data profiling and/or in response to re-encoding trace events. Since aggregation over hash-encoded columns is slower than over value-encoded columns, value encoding may be specified as a hint for such columns. It is not guaranteed that the preference is applied. It is a hint as opposed to a setting. To specify an encoding hint, set the EncodingHint property on the column. Possible values are "Default", "Value" and "Hash". The following snippet of

JSON-based metadata from the Model.bim file specifies value encoding for the Sales Amount column.

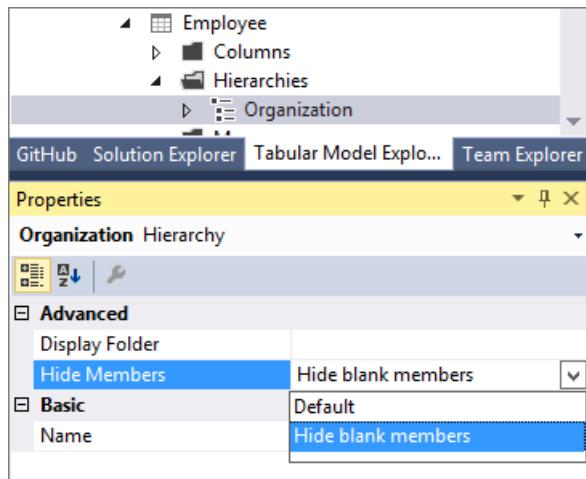

```
{  
    "name": "Sales Amount",  
    "dataType": "decimal",  
    "sourceColumn": "SalesAmount",  
    "formatString": "\\\$#,0.00;(\\\$#,0.00);\\\$#,0.00",  
    "sourceProviderType": "Currency",  
    "encodingHint": "Value"  
}
```

Ragged hierarchies

In tabular models, you can model parent-child hierarchies. Hierarchies with a differing number of levels are often referred to as ragged hierarchies. By default, ragged hierarchies are displayed with blanks for levels below the lowest child. Here's an example of a ragged hierarchy in an organizational chart:

	A	B
1	Row Labels	Reseller Total Sales
2	Ken Sánchez	\$80,450,596.98
3	Brian Welcker	\$80,450,596.98
4	Amy Alberts	\$15,535,946.26
5		\$732,078.44
6		\$732,078.44
7		\$732,078.44
8	Jae Pak	\$8,503,338.65
9	Rachel Valdez	\$1,790,640.23
10	Ranjit Varkey Chudukatil	\$4,509,888.93
11	Stephen Jiang	\$63,320,315.35
12		\$1,092,123.86
13	David Campbell	\$3,729,945.35
14		\$3,729,945.35

This release introduces the **Hide Members** property. You can set the **Hide Members** property for a hierarchy to **Hide blank members**.

NOTE

Blank members in the model are represented by a DAX blank value, not an empty string.

When set to **Hide blank members**, and the model deployed, an easier to read version of the hierarchy is shown in reporting clients like Excel.

A	B
1 Row Labels	Reseller Total Units
2 Ken Sánchez	209,274
3 Brian Welcker	209,274
4 Amy Alberts	47,214
5 Jae Pak	26,231
6 Rachel Valdez	6,898
7 Ranjit Varkey Chudukatil	14,085
8 Stephen Jiang	157,112
9 David Campbell	8,172
10 Garrett Vargas	11,544

Detail Rows

You can now define a custom row set contributing to a measure value. Detail Rows is similar to the default drillthrough action in multidimensional models. This allows end-users to view information in more detail than the aggregated level.

The following PivotTable shows Internet Total Sales by year from the Adventure Works sample tabular model. You can right-click a cell with an aggregated value from the measure and then click **Show Details** to view the detail rows.

A	B
1 Row Labels	Internet Total Sale
2 +2010	\$43,421.04
3 +2011	\$7,075,525.9
4 +2012	\$5,842,485.2
5 +2013	\$16,351,550.3
6 +2014	\$45,694.7
7 Grand Total	\$29,358,677.2
8	
9	
10	
11	
12	
13	
14	
15	
16	
17	
18	
19	

By default, the associated data in the Internet Sales table is displayed. This limited behavior is often not meaningful for the user because the table may not have the necessary columns to show useful information such as customer name and order information. With Detail Rows, you can specify a **Detail Rows Expression** property for measures.

Detail Rows Expression property for measures

The **Detail Rows Expression** property for measures allows model authors to customize the columns and rows returned to the end-user.

The `SELECTCOLUMNS` DAX function is commonly used in a Detail Rows Expression. The following example defines the columns to be returned for rows in the Internet Sales table in the sample Adventure Works tabular model:

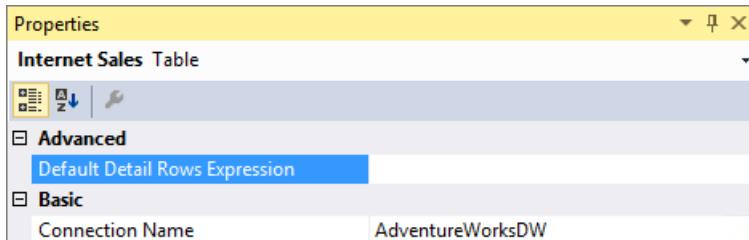

```
SELECTCOLUMNS(
    'Internet Sales',
    "Customer First Name", RELATED( Customer[Last Name]),
    "Customer Last Name", RELATED( Customer[First Name]),
    "Order Date", 'Internet Sales'[Order Date],
    "Internet Total Sales", [Internet Total Sales]
)
```

With the property defined and the model deployed, a custom row set is returned when the user selects **Show Details**. It automatically honors the filter context of the cell that was selected. In this example, only the rows for 2010 value are displayed:

	A	B	C	D
1	Data returned for Internet Total Sales, 2010 (First 1000 rows).			
2				
3	[Customer First Name] ▾ [Customer Last Name] ▾ [Order Date] ▾ [Internet Total Sales] ▾			
4	Colin	Anand	12/30/2010	3578.27
5	Edward	Brown	12/31/2010	3578.27
6	Emma	Brown	12/31/2010	3578.27
7	Ruben	Prasad	12/29/2010	699.0982
8	Sydney	Wright	12/29/2010	3399.99

Default Detail Rows Expression property for tables

In addition to measures, tables also have a property to define a detail rows expression. The **Default Detail Rows Expression** property acts as the default for all measures within the table. Measures that do not have their own expression defined inherit the expression from the table and show the row set defined for the table. This allows reuse of expressions, and new measures added to the table later automatically inherits the expression.

DETAILROWS DAX Function

Included in this release is a new `DETAILROWS` DAX function that returns the row set defined by the detail rows expression. It works similarly to the `DRILLTHROUGH` statement in MDX, which is also compatible with detail rows expressions defined in tabular models.

The following DAX query returns the row set defined by the detail rows expression for the measure or its table. If no expression is defined, the data for the Internet Sales table is returned because it's the table containing the measure.

```
EVALUATE DETAILROWS([Internet Total Sales])
```

Object-level security

This release introduces [object-level security](#) for tables and columns. In addition to restricting access to table and column data, sensitive table and column names can be secured. This helps prevent a malicious user from discovering such a table exists.

Object-level security must be set using the JSON-based metadata, Tabular Model Scripting Language (TMSL), or

Tabular Object Model (TOM).

For example, the following code helps secure the Product table in the sample Adventure Works tabular model by setting the **MetadataPermission** property of the **TablePermission** class to **None**.

```
//Find the Users role in Adventure Works and secure the Product table
ModelRole role = db.Model.Roles.Find("Users");
Table productTable = db.Model.Tables.Find("Product");
if (role != null && productTable != null)
{
    TablePermission tablePermission;
    if (role.TablePermissions.Contains(productTable.Name))
    {
        tablePermission = role.TablePermissions[productTable.Name];
    }
    else
    {
        tablePermission = new TablePermission();
        role.TablePermissions.Add(tablePermission);
        tablePermission.Table = productTable;
    }
    tablePermission.MetadataPermission = MetadataPermission.None;
}
db.Update(UpdateOptions.ExpandFull);
```

Dynamic Management Views (DMVs)

DMVs are queries in SQL Server Profiler that return information about local server operations and server health. This release includes improvements to [Dynamic Management Views \(DMV\)](#) for tabular models at the 1200 and 1400 compatibility levels.

[DISCOVER_CALC_DEPENDENCY](#) Now works with tabular 1200 and higher models. Tabular 1400 and higher models show dependencies between M partitions, M expressions and structured data sources. To learn more, see the [Analysis Services blog](#).

[MDSHEMA_MEASUREGROUP_DIMENSIONS](#) Improvements are included for this DMV, which is used by various client tools to show measure dimensionality. For example, the Explore feature in Excel Pivot Tables allows the user to cross-drill to dimensions related to the selected measures. This release corrects the cardinality columns, which were previously showing incorrect values.

DAX enhancements

One of the most important pieces of new DAX functionality is the new [IN Operator / CONTAINSROW Function](#) for DAX expressions. This is similar to the `TSQL IN` operator commonly used to specify multiple values in a `WHERE` clause.

Previously, it was common to specify multi-value filters using the logical `OR` operator, like in the following measure expression:

```
Filtered Sales:=CALCULATE (
    [Internet Total Sales],
    'Product'[Color] = "Red"
    || 'Product'[Color] = "Blue"
    || 'Product'[Color] = "Black"
)
```

This is simplified using the `IN` operator:

```
Filtered Sales:=CALCULATE (
    [Internet Total Sales], 'Product'[Color] IN { "Red", "Blue", "Black" }
)
```

In this case, the `IN` operator refers to a single-column table with 3 rows; one for each of the specified colors. Note the table constructor syntax uses curly braces.

The `IN` operator is functionally equivalent to the `CONTAINSROW` function:

```
Filtered Sales:=CALCULATE (
    [Internet Total Sales], CONTAINSROW({ "Red", "Blue", "Black" }, 'Product'[Color])
)
```

The `IN` operator can also be used effectively with table constructors. For example, the following measure filters by combinations of product color and category:

```
Filtered Sales:=CALCULATE (
    [Internet Total Sales],
    FILTER( ALL('Product'),
        ( 'Product'[Color] = "Red" && Product[Product Category Name] = "Accessories" )
        || ( 'Product'[Color] = "Blue" && Product[Product Category Name] = "Bikes" )
        || ( 'Product'[Color] = "Black" && Product[Product Category Name] = "Clothing" )
    )
)
```

By using the new `IN` operator, the measure expression above is now equivalent to the one below:

```
Filtered Sales:=CALCULATE (
    [Internet Total Sales],
    FILTER( ALL('Product'),
        ('Product'[Color], Product[Product Category Name]) IN
        { ( "Red", "Accessories" ), ( "Blue", "Bikes" ), ( "Black", "Clothing" ) }
    )
)
```

Additional improvements

In addition to all the new features, Analysis Services, SSDT, and SSMS also include the following improvements:

- Hierarchy and column reuse surfaced in more helpful locations in the Power BI field list.
- Date relationships to easily create relationships to date dimensions based on date fields.
- Default installation option for Analysis Services is now for tabular mode.
- New Get Data (Power Query) data sources.
- DAX Editor for SSDT.
- Existing DirectQuery data sources support for M queries.
- SSMS improvements, such as viewing, editing, and scripting support for structured data sources.

SQL Server 2016 Analysis Services

SQL Server 2016 Analysis Services includes many new enhancements providing improved performance, easier solution authoring, automated database management, enhanced relationships with bi-directional cross filtering, parallel partition processing, and much more. At the heart of most enhancements for this release is the new 1200 compatibility level for tabular model databases.

SQL Server 2016 Service Pack 1 (SP1) Analysis Services

[Download SQL Server 2016 SP1](#)

SQL Server 2016 Service Pack 1 Analysis Services provides improved performance and scalability through Non-Uniform Memory Access (NUMA) awareness and optimized memory allocation based on **Intel Threading Building Blocks** (Intel TBB). This new functionality helps lower Total Cost of Ownership (TCO) by supporting more users on fewer, more powerful enterprise servers.

In particular, SQL Server 2016 SP1 Analysis Services features improvements in these key areas:

- **NUMA awareness** - For better NUMA support, the in-memory (VertiPaq) engine inside Analysis Services now maintains a separate job queue on each NUMA node. This guarantees the segment scan jobs run on the same node where the memory is allocated for the segment data. Note, NUMA awareness is only enabled by default on systems with at least four NUMA nodes. On two-node systems, the costs of accessing remote allocated memory generally doesn't warrant the overhead of managing NUMA specifics.
- **Memory allocation** - Analysis Services has been accelerated with Intel Threading Building Blocks, a scalable allocator that provides separate memory pools for every core. As the number of cores increases, the system can scale almost linearly.
- **Heap fragmentation** - The Intel TBB-based scalable allocator also helps to mitigate performance problems due to heap fragmentation that have been shown to occur with the Windows Heap.

Performance and scalability testing showed significant gains in query throughput when running SQL Server 2016 SP1 Analysis Services on large multi-node enterprise servers.

While most enhancements in this release are specific to tabular models, a number of enhancements have been made to multidimensional models; for example, distinct count ROLAP optimization for data sources like DB2 and Oracle, drill-through multi-selection support with Excel 2016, and Excel query optimizations.

SQL Server 2016 General Availability (GA) Analysis Services

Modeling

Improved modeling performance for tabular 1200 models

For tabular 1200 models, metadata operations in SSDT are much faster than tabular 1100 or 1103 models. By comparison, on the same hardware, creating a relationship on a model set to the SQL Server 2014 compatibility level (1103) with 23 tables takes 3 seconds, whereas the same relationship on a model created set to compatibility level 1200 takes just under a second.

Project templates added for tabular 1200 models in SSDT

With this release, you no longer need two versions of SSDT for building relational and BI projects. [SQL Server Data Tools for Visual Studio 2015](#) adds project templates for Analysis Services solutions, including **Analysis Services Tabular Projects** used for building models at the 1200 compatibility level. Other Analysis Services project templates for multidimensional and data mining solutions are also included, but at the same functional level (1100 or 1103) as in previous releases.

Display folders

Display folders are now available for tabular 1200 models. Defined in SQL Server Data Tools and rendered in client applications like Excel or Power BI Desktop, display folders help you organize large numbers of measures into individual folders, adding a visual hierarchy for easier navigation in field lists.

Bi-directional cross filtering

New in this release is a built-in approach for enabling bi-directional cross filters in tabular models, eliminating the need for hand-crafted DAX workarounds for propagating filter context across table relationships. Filters are only auto-generated when the direction can be established with a high degree of certainty. If there is ambiguity in the form of multiple query paths across table relationships, a filter won't be created automatically. See [Bi-directional cross filters for tabular models in SQL Server 2016 Analysis Services](#) for details.

Translations

You can now store translated metadata in a tabular 1200 model. Metadata in the model includes fields for **Culture**,

translated captions, and translated descriptions. To add translations, use the **Model > Translations** command in Visual Studio with Analysis Services projects. See [Translations in tabular models \(Analysis Services\)](#) for details.

Pasted tables

You can now upgrade an 1100 or 1103 tabular model to 1200 when the model contains pasted tables. We recommend using Visual Studio with Analysis Services projects. In SSDT, set **CompatibilityLevel** to 1200 and then deploy to a SQL Server 2017 instance of Analysis Services. See [Compatibility Level for Tabular models in Analysis Services](#) for details.

Calculated tables in SSDT

A *calculated table* is a model-only construction based on a DAX expression or query in SSDT. When deployed in a database, a calculated table is indistinguishable from regular tables.

There are several uses for calculated tables, including the creation of new tables to expose an existing table in a specific role. The classic example is a Date table that operates in multiple contexts (order date, ship date, and so forth). By creating a calculated table for a given role, you can now activate a table relationship to facilitate queries or data interaction using the calculated table. Another use for calculated tables is to combine parts of existing tables into an entirely new table that exists only in the model. See [Create a Calculated Table](#) to learn more.

Formula fixup

With formula fixup on a tabular 1200 model, SSDT will automatically update any measures that is referencing a column or table that was renamed.

Support for Visual Studio configuration manager

To support multiple environments, like Test and Pre-production environments, Visual Studio allows developers to create multiple project configurations using the configuration manager. Multidimensional models already leverage this but tabular models did not. With this release, you can now use configuration manager to deploy to different servers.

Instance management

Administer Tabular 1200 models in SSMS

In this release, an Analysis Services instance in Tabular server mode can run tabular models at any compatibility level (1100, 1103, 1200). The latest [SQL Server Management Studio](#) is updated to display properties and provide database model administration for tabular models at the 1200 compatibility level.

Parallel processing for multiple table partitions in tabular models

This release includes new parallel processing functionality for tables with two or more partitions, increasing processing performance. There are no configuration settings for this feature. For more information about configuring partitions and processing tables, see [Tabular Model Partitions](#).

Add computer accounts as Administrators in SSMS

Analysis Services administrators can now use SQL Server Management Studio to configure computer accounts to be members of the Analysis Services administrators group. In the **Select Users or Groups** dialog, set the **Locations** for the computers domain and then add the **Computers** object type. For more information, see [Grant server admin rights to an Analysis Services instance](#).

DBCC for Analysis Services

Database Consistency Checker (DBCC) runs internally to detect potential data corruption issues on database load, but can also be run on demand if you suspect problems in your data or model. DBCC runs different checks depending on whether the model is tabular or multidimensional. See [Database Consistency Checker \(DBCC\) for Analysis Services tabular and multidimensional databases](#) for details.

Extended Events updates

This release adds a graphical user interface to SQL Server Management Studio to configure and manage Analysis Services Extended Events. You can set up live data streams to monitor server activity in real time, keep session data loaded in memory for faster analysis, or save data streams to a file for offline analysis. For more information, see [Monitor Analysis Services with SQL Server Extended Events](#) and [Using extended events with Analysis Services](#)

(Guy in a Cube blog post and video).

Scripting

PowerShell for Tabular models

This release includes PowerShell enhancements for tabular models at compatibility level 1200. You can use all of the applicable cmdlets, plus cmdlets specific to Tabular mode: `Invoke-ProcessASDatabase` and `Invoke-ProcessTable` cmdlet.

SSMS scripting database operations

In the [latest SQL Server Management Studio \(SSMS\)](#), script is now enabled for database commands, including Create, Alter, Delete, Backup, Restore, Attach, Detach. Output is Tabular Model Scripting Language (TMSL) in JSON. See [Tabular Model Scripting Language \(TMSL\) Reference](#) for more information.

Analysis Services Execute DDL Task

Analysis Services Execute DDL Task now also accepts Tabular Model Scripting Language (TMSL) commands.

SSAS PowerShell cmdlet

SSAS PowerShell cmdlet **Invoke-ASCmd** now accepts Tabular Model Scripting Language (TMSL) commands. Other SSAS PowerShell cmdlets may be updated in a future release to use the new tabular metadata (exceptions will be called out in the release notes).

See Analysis Services PowerShell Reference for details.

Tabular Model Scripting Language (TMSL) supported in SSMS

Using the [latest version of SSMS](#), you can now create scripts to automate most administrative tasks for tabular 1200 models. Currently, the following tasks can be scripted: Process at any level, plus CREATE, ALTER, DELETE at the database level.

Functionally, TMSL is equivalent to the XMLA ASSL extension that provides multidimensional object definitions, except that TMSL uses native descriptors like **model**, **table**, and **relationship** to describe tabular metadata. See [Tabular Model Scripting Language \(TMSL\) Reference](#) for details about the schema.

A generated JSON-based script for a tabular model might look like the following:

```
{  
  "create": {  
    "database": {  
      "name": "AdventureWorksTabular1200",  
      "id": "AdventureWorksTabular1200",  
      "compatibilityLevel": 1200,  
      "readWriteMode": "readWrite",  
      "model": {}  
    }  
  }  
}
```

The payload is a JSON document that can be as minimal as the example shown above, or highly embellished with the full set of object definitions. [Tabular Model Scripting Language \(TMSL\) Reference](#) describes the syntax.

At the database level, CREATE, ALTER, and DELETE commands will output TMSL script in the familiar XMLA window. Other commands, such as Process, can also be scripted in this release. Script support for many other actions may be added in a future release.

SCRIPTABLE COMMANDS	DESCRIPTION
create	Adds a database, connection, or partition. The ASSL equivalent is CREATE.

SCRIPTABLE COMMANDS	DESCRIPTION
createOrReplace	Updates an existing object definition (database, connection, or partition) by overwriting a previous version. The ASSL equivalent is ALTER with AllowOverwrite set to true and ObjectDefinition to ExpandFull.
delete	Removes an object definition. ASSL equivalent is DELETE.
refresh	Processes the object. ASSL equivalent is PROCESS.

DAX

Improved DAX formula editing

Updates to the formula bar help you write formulas with more ease by differentiating functions, fields and measures using syntax coloring, it provides intelligent function and field suggestions and tells you if parts of your DAX expression are wrong using error *squiggles*. It also allows you to use multiple lines (Alt + Enter) and indentation (Tab). The formula bar now also allows you to write comments as part of your measures, just type "://" and everything after these characters on the same line will be considered a comment.

DAX variables

This release now includes support for variables in DAX. Variables can now store the result of an expression as a named variable, which can then be passed as an argument to other measure expressions. Once resultant values have been calculated for a variable expression, those values do not change, even if the variable is referenced in another expression. For more information, see [VAR Function](#).

New DAX functions

With this release, DAX introduces over fifty new functions to support faster calculations and enhanced visualizations in Power BI. To learn more, see [New DAX Functions](#).

Save incomplete measures

You can now save incomplete DAX measures directly in a tabular 1200 model project and pick it up again when you are ready to continue.

Additional DAX enhancements

- Non empty calculation - Reduces the number of scans needed for non empty.
- Measure Fusion - Multiple measures from the same table will be combined into a single storage engine - query.
- Grouping sets - When a query asks for measures at multiple granularities (Total/Year/Month), a single - query is sent at the lowest level and the rest of the granularities are derived from the lowest level.
- Redundant join elimination - A single query to the storage engine returns both the dimension columns and the measure values.
- Strict evaluation of IF/SWITCH - A branch whose condition is false will no longer result in storage engine queries. Previously, branches were eagerly evaluated but results discarded later on.

Developer

[Microsoft.AnalysisServices.Tabular namespace for Tabular 1200 programmability in AMO](#)

Analysis Services Management Objects (AMO) is updated to include a new tabular namespace for managing a Tabular Mode instance of SQL Server 2016 Analysis Services, as well as provide the data definition language for creating or modifying tabular 1200 models programmatically. Visit [Microsoft.AnalysisServices.Tabular](#) to read up on the API.

Analysis Services Management Objects (AMO) updates

[Analysis Services Management Objects \(AMO\)](#) has been re-factored to include a second assembly, Microsoft.AnalysisServices.Core.dll. The new assembly separates out common classes like Server, Database, and Role that have broad application in Analysis Services, irrespective of server mode. Previously, these classes were part of the original Microsoft.AnalysisServices assembly. Moving them to a new assembly paves the way for future

extensions to AMO, with clear division between generic and context-specific APIs. Existing applications are unaffected by the new assemblies. However, should you choose to rebuild applications using the new AMO assembly for any reason, be sure to add a reference to Microsoft.AnalysisServices.Core. Similarly, PowerShell scripts that load and call into AMO must now load Microsoft.AnalysisServices.Core.dll. Be sure to update any scripts.

JSON editor for BIM files

Code View in Visual Studio 2015 now renders the BIM file in JSON format for tabular 1200 models. The version of Visual Studio determines whether the BIM file is rendered in JSON via the built-in JSON Editor, or as simple text.

To use the JSON editor, with the ability to expand and collapse sections of the model, you will need the latest version of SQL Server Data Tools plus Visual Studio 2015 (any edition, including the free Community edition). For all other versions of SSDT or Visual Studio, the BIM file is rendered in JSON as simple text. At a minimum, an empty model will contain the following JSON:

```
```json
{
 "name": "SemanticModel",
 "id": "SemanticModel",
 "compatibilityLevel": 1200,
 "readWriteMode": "ReadWrite",
 "model": {}
}
```

```

WARNING

Avoid editing the JSON directly. Doing so can corrupt the model.

New elements in MS-CSDLBI 2.0 schema

The following elements have been added to the **TProperty** complex type defined in the [MS-CSDLBI] 2.0 schema:

| ELEMENT | DEFINITION |
|--------------|--|
| DefaultValue | A property that specifies the value used when evaluating the query. The DefaultValue property is optional, but it is automatically selected if the values from the member cannot be aggregated. |
| Statistics | A set of statistics from the underlying data that is associated with the column. These statistics are defined by the TPropertyStatistics complex type and are provided only if they are not computationally expensive to generate, as described in section 2.1.13.5 of the Conceptual Schema Definition File Format with Business Intelligence Annotations document. |

DirectQuery

New DirectQuery implementation

This release sees significant enhancements in DirectQuery for tabular 1200 models. Here's a summary:

- DirectQuery now generates simpler queries that provide better performance.
- Extra control over defining sample datasets used for model design and testing.
- Row level security (RLS) is now supported for tabular 1200 models in DirectQuery mode. Previously, the presence of RLS prevented deploying a tabular model in DirectQuery mode.
- Calculated columns are now supported for tabular 1200 models in DirectQuery mode. Previously, the presence

of calculated columns prevented deploying a tabular model in DirectQuery mode.

- Performance optimizations include redundant join elimination for VertiPaq and DirectQuery.

New data sources for DirectQuery mode

Data sources supported for tabular 1200 models in DirectQuery mode now include Oracle, Teradata and Microsoft Analytics Platform (formerly known as Parallel Data Warehouse). To learn more, see [DirectQuery Mode](#).

Earlier versions

[SQL Server 2014 Analysis Services](#)

Analysis Services features supported by SQL Server editions

10/22/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

This article describes features supported by different editions of SQL Server 2016, 2017, 2019 Analysis Services. Evaluation edition supports Enterprise edition features.

Analysis Services (servers)

| FEATURE | ENTERPRISE | STANDARD | WEB | EXPRESS WITH ADVANCED SERVICES | EXPRESS WITH TOOLS | EXPRESS | DEVELOPER |
|--|--|----------------------------|-----|--------------------------------|--------------------|---------|--|
| Scalable shared databases | Yes | | | | | | Yes |
| Backup/Restore & Attach/Detach databases | Yes | Yes | | | | | Yes |
| Synchronize databases | Yes | | | | | | Yes |
| Failover cluster instances | Yes
Number of nodes is the operating system maximum | Yes
Support for 2 nodes | | | | | Yes
Number of nodes is the operating system maximum |
| Programmability (AMO, ADOMD.NET, OLEDB, XML/A, ASSL, TMSL) | Yes | Yes | | | | | Yes |

Tabular models

| Feature | Enterprise | Standard | Web | Express with Advanced Services | Express with Tools | Express | Developer |
|--|---|---|-----|--------------------------------|--------------------|---------|---|
| Hierarchies | Yes | Yes | | | | | Yes |
| KPIs | Yes | Yes | | | | | Yes |
| Perspectives | Yes | | | | | | Yes |
| Translations | Yes | Yes | | | | | Yes |
| DAX calculations, DAX queries, MDX queries | Yes | Yes | | | | | Yes |
| Row-level security | Yes | Yes | | | | | Yes |
| Multiple partitions | Yes | | | | | | Yes |
| Calculation groups | Yes
(beginning with SQL Server 2019) | Yes
(beginning with SQL Server 2019) | | | | | Yes
(beginning with SQL Server 2019) |
| Query interleaving | Yes
(beginning with SQL Server 2019) | Yes
(beginning with SQL Server 2019) | | | | | Yes
(beginning with SQL Server 2019) |
| Many-to-many relationships | Yes
(beginning with SQL Server 2019) | Yes
(beginning with SQL Server 2019) | | | | | Yes
(beginning with SQL Server 2019) |
| In-memory storage mode | Yes | Yes | | | | | Yes |
| DirectQuery mode | Yes | Yes
(beginning with SQL Server 2019) | | | | | Yes |

Multidimensional models

| Feature | Enterprise | Standard | Web | Express with Advanced Services | Express with Tools | Express | Developer |
|---|------------------|------------------|-----|--------------------------------|--------------------|---------|------------------|
| Semi-additive measures | Yes | No ¹ | | | | | Yes |
| Hierarchies | Yes | Yes | | | | | Yes |
| KPIs | Yes | Yes | | | | | Yes |
| Perspectives | Yes | | | | | | Yes |
| Actions | Yes | Yes | | | | | Yes |
| Account intelligence | Yes | Yes | | | | | Yes |
| Time intelligence | Yes | Yes | | | | | Yes |
| Custom rollups | Yes | Yes | | | | | Yes |
| Writeback cube | Yes | Yes | | | | | Yes |
| Writeback dimensions | Yes ² | | | | | | Yes ² |
| Writeback cells | Yes | Yes | | | | | Yes |
| Drillthrough | Yes | Yes | | | | | Yes |
| Advanced hierarchy types (parent-child and ragged hierarchies) | Yes | Yes | | | | | Yes |
| Advanced dimensions (reference dimensions, many-to-many dimensions) | Yes | Yes | | | | | Yes |
| Linked measures and dimensions | Yes | Yes ³ | | | | | Yes |

| Feature | Enterprise | Standard | Web | Express with Advanced Services | Express with Tools | Express | Developer |
|--|------------|--------------|-----|--------------------------------|--------------------|---------|-----------|
| Translations | Yes | Yes | | | | | Yes |
| Aggregations | Yes | Yes | | | | | Yes |
| Multiple partitions | Yes | Yes, up to 3 | | | | | Yes |
| Proactive caching | Yes | | | | | | Yes |
| Custom assemblies (stored procedures) | Yes | Yes | | | | | Yes |
| MDX queries and scripts | Yes | Yes | | | | | Yes |
| DAX queries | Yes | Yes | | | | | Yes |
| Role-based security model | Yes | Yes | | | | | Yes |
| Dimension and cell-level security | Yes | Yes | | | | | Yes |
| Scalable string storage | Yes | Yes | | | | | Yes |
| MOLAP, ROLAP, and HOLAP storage models | Yes | Yes | | | | | Yes |
| Binary and compressed XML transport | Yes | Yes | | | | | Yes |
| Push-mode processing | Yes | | | | | | Yes |
| Measure expressions | Yes | | | | | | Yes |

[1] The LastChild semi-additive measure is supported in Standard edition, but other semi-additive measures, such as None, FirstChild, FirstNonEmpty, LastNonEmpty, AverageOfChildren, and ByAccount, are not. Additive measures, such as Sum, Count, Min, Max, and non-additive measures (DistinctCount) are supported on all editions.

[2] Writeback dimensions are discontinued in SQL Server Analysis Services 2019 and later.

[3] Standard edition supports linking measures and dimensions within the same database, but not from other databases or instances.

Power Pivot for SharePoint

| FEATURE | ENTERPRISE | STANDARD | WEB | EXPRESS WITH ADVANCED SERVICES | EXPRESS WITH TOOLS | EXPRESS | DEVELOPER |
|--|------------|----------|-----|--------------------------------|--------------------|---------|-----------|
| SharePoint farm integration based on shared service architecture | Yes | | | | | | Yes |
| Usage reporting | Yes | | | | | | Yes |
| Health monitoring rules | Yes | | | | | | Yes |
| Power Pivot gallery | Yes | | | | | | Yes |
| Power Pivot data refresh | Yes | | | | | | Yes |
| Power Pivot data feeds | Yes | | | | | | Yes |

Data Mining

NOTE

Data mining is [deprecated](#) in SQL Server Analysis Services 2017.

| FEATURE NAME | ENTERPRISE | STANDARD | WEB | EXPRESS WITH ADVANCED SERVICES | EXPRESS WITH TOOLS | EXPRESS | DEVELOPER |
|---------------------|------------|----------|-----|--------------------------------|--------------------|---------|-----------|

| Multiple prediction targets for naïve Bayes, neural network and logistic regression | Yes | | | | | | Yes |

SQL Server Analysis Services backward compatibility (2019, 2017, 2016)

10/22/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

This article describes changes in feature availability and behavior between the current version and the previous versions.

Definitions

A *deprecated feature* will be discontinued from the product in a future release, but is still supported and included in the current release to maintain backward compatibility. It's recommended you discontinue using deprecated features in new and existing projects to maintain compatibility with future releases. Documentation is not updated for deprecated features.

A *discontinued feature* was deprecated in an earlier release. It may continue to be included in the current release, but is no longer supported. Discontinued features may be removed entirely in a future release or update.

A *breaking change* causes a feature, data model, application code, or script to no longer function after upgrading to the current release.

A *behavior change* affects how the same feature works in the current release as compared to the previous release. Only significant behavior changes are described. Changes in user interface are not included.

SQL Server 2019

Deprecated features

There are no deprecated features announced with this release.

Discontinued features

There are no discontinued features announced with this release.

Breaking changes

There are no breaking changes in this release.

Behavior changes

There are no breaking changes in this release.

SQL Server 2017

Deprecated features

The following features are deprecated in this release:

| Mode/Category | Feature |
|------------------|-------------|
| Multidimensional | Data Mining |

| | |
|---|---|
| Multidimensional | Remote linked measure groups |
| Tabular | Models at the 1100 and 1103 compatibility level |
| Tabular | Tabular Object Model properties: Column.TableDetailPosition, Column.IsDefaultLabel, Column.IsDefaultImage |
| Tools | <p>SQL Server Profiler for Trace Capture</p> <p>The replacement is to use Extended Events Profiler embedded in SQL Server Management Studio.</p> <p>See Monitor Analysis Services with SQL Server Extended Events.</p> |
| Tools | <p>Server Profiler for Trace Replay</p> <p>Replacement. There is no replacement.</p> |
| Trace Management Objects and Trace APIs | <p>Microsoft.AnalysisServices.Trace objects (contains the APIs for Analysis Services Trace and Replay objects). The replacement is multi-part:</p> <ul style="list-style-type: none"> - Trace Configuration: Microsoft.SqlServer.Management.XEvent - Trace Reading: Microsoft.SqlServer.XEvent.Linq - Trace Replay: None |

Discontinued features

The following features were deprecated in an earlier release and are no longer supported in this release.

| Mode/Category | Feature |
|------------------|--|
| Tabular | VertipaqPagingPolicy memory property value (2), enable paging to disk using memory mapped files. |
| Multidimensional | Remote partitions |
| Multidimensional | Remote linked measure groups |
| Multidimensional | Dimensional writeback |
| Multidimensional | Linked dimensions |

Breaking changes

There are no breaking changes in this release.

Behavior changes

Changes to MDSHEMA_MEASUREGROUP_DIMENSIONS and DISCOVER_CALC_DEPENDENCY, detailed in the [What's new in SQL Server 2017 CTP 2.1 for Analysis Services](#) announcement.

SQL Server 2016

Deprecated features

The following features are deprecated in this release:

| Mode/Category | Feature |
|---|---|
| Multidimensional | Remote partitions |
| Multidimensional | Remote linked measure groups |
| Multidimensional | Dimensional writeback |
| Multidimensional | Linked dimensions |
| Multidimensional | SQL Server table notifications for proactive caching.
The replacement is to use polling for proactive caching.
See Proactive Caching (Dimensions) and Proactive Caching (Partitions) . |
| Multidimensional | Session cubes. There is no replacement. |
| Multidimensional | Local cubes. There is no replacement. |
| Tabular | Tabular model 1100 and 1103 compatibility levels will not be supported in a future release. The replacement is to set models at compatibility level 1200 or higher, converting model definitions to tabular metadata. See Compatibility Level for Tabular models in Analysis Services . |
| Tools | SQL Server Profiler for Trace Capture

The replacement is to use Extended Events Profiler embedded in SQL Server Management Studio.
See Monitor Analysis Services with SQL Server Extended Events . |
| Tools | Server Profiler for Trace Replay
Replacement. There is no replacement. |
| Trace Management Objects and Trace APIs | Microsoft.AnalysisServices.Trace objects (contains the APIs for Analysis Services Trace and Replay objects). The replacement is multi-part:

- Trace Configuration: Microsoft.SqlServer.Management.XEvent
- Trace Reading: Microsoft.SqlServer.XEvent.Linq
- Trace Replay: None |

NOTE

Previously deprecated feature announcements from SQL Server 2014 (12.x) remain in effect. Because the code supporting those features has not yet been cut from the product, many of these features are still present in this release. While previously deprecated features might be accessible, they are still considered deprecated and could be physically removed from the product at any time.

Discontinued features

The following features were deprecated in an earlier release and are no longer supported in this release.

| Feature | Replacement or workaround |
|--|---|
| CalculationPassValue (MDX) | None. This feature was deprecated in SQL Server 2005. |
| CalculationCurrentPass (MDX) | None. This feature was deprecated in SQL Server 2005. |
| NON_EMPTY_BEHAVIOR query optimizer hint | None. This feature was deprecated in SQL Server 2008. |
| COM assemblies | None. This feature was deprecated in SQL Server 2008. |
| CELL_EVALUATION_LIST intrinsic cell property | None. This feature was deprecated in SQL Server 2005. |

NOTE

Previously deprecated feature announcements from SQL Server 2014 (12.x) remain in effect. Because the code supporting those features has not yet been cut from the product, many of these features are still present in this release. While previously deprecated features might be accessible, they are still considered deprecated and could be physically removed from the product at any time.

Breaking changes

.NET 4.0 version upgrade

Analysis Services Management Objects (AMO), ADOMD.NET, and Tabular Object Model (TOM) client libraries now target the .NET 4.0 runtime. This can be a breaking change for applications that target .NET 3.5. Applications using newer versions of these assemblies must now target .NET 4.0 or later.

AMO version upgrade

This release is a version upgrade for [Analysis Services Management Objects \(AMO\)](#) and is a breaking change under certain circumstances. Existing code and scripts that call into AMO will continue to run as before if you upgrade from a previous version. However, if you need to *recompile* your application and you are targeting a SQL Server 2016 Analysis Services instance, you must add the following namespace to make your code or script operational:

```
using Microsoft.AnalysisServices;
using Microsoft.AnalysisServices.Core;
```

The [Microsoft.AnalysisServices.Core](#) namespace is now required whenever you reference the Microsoft.AnalysisServices assembly in your code. Objects that were previously only in the **Microsoft.AnalysisServices** namespace are moved to the Core namespace in this release if the object is used the same way in both tabular and multidimensional scenarios. For example, server-related APIs are relocated to the Core namespace.

Although there are now multiple namespaces, both exist in the same assembly (Microsoft.AnalysisServices.dll).

XEvent DISCOVER changes

To better support XEvent DISCOVER streaming in SSMS for SQL Server 2016 Analysis Services,

`DISCOVER_XEVENT_TRACE_DEFINITION` is replaced with the following XEvent traces:

- DISCOVER_XEVENT_PACKAGES
- DISCOVER_XEVENT_OBJECT
- DISCOVER_XEVENT_OBJECT_COLUMNS

- DISCOVER_XEVENT_SESSION_TARGETS

Behavior changes

Revisions to default values, manual configuration required to complete an upgrade or restore functionality, or a new implementation of an existing feature are all examples of a behavior change in the product.

Feature behaviors that changed in this release, yet do not break an existing model or code post-upgrade, are listed here.

Analysis Services in SharePoint mode

Running the Power Pivot Configuration wizard is no longer required as a post-installation task. This is true for all supported versions of SharePoint that load models from the current SQL Server 2016 Analysis Services.

DirectQuery mode for Tabular models

DirectQuery is a data access mode for tabular models, where query execution is performed on a backend relational database, retrieving a result set in real time. It's often used for very large datasets that cannot fit in memory or when data is volatile and you want the most recent data returned in queries against a tabular model.

DirectQuery has existed as a data access mode for the last several releases. In SQL Server 2016 Analysis Services, the implementation has been slightly revised, assuming the tabular model is at compatibility level 1200 or higher. DirectQuery has fewer restrictions than before. It also has different database properties.

If you are using DirectQuery in an existing tabular model, you can keep the model at its currently compatibility level of 1100 or 1103 and continue to use DirectQuery as its implemented for those levels. Alternatively, you can upgrade to 1200 or higher to benefit from enhancements made to DirectQuery.

There is no in-place upgrade of a DirectQuery model because the settings from older compatibility levels do not have exact counterparts in the newer 1200 and higher compatibility levels. If you have an existing tabular model that runs in DirectQuery mode, you should open the model in SQL Server Data Tools, turn DirectQuery off, set the **Compatibility Level** property to 1200 or higher, and then reconfigure the DirectQuery properties. See [DirectQuery Mode](#) for details.

Power Pivot for SharePoint

9/12/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services (2016 and later) ✗ Azure Analysis Services ✗ Power BI Premium

Analysis Services in Power Pivot mode provides server hosting of Power Pivot data in a SharePoint farm. Power Pivot data is an analytical data model users create with Power Pivot in Excel. Server hosting of workbooks requires SharePoint, Excel Services, and an installation of Power Pivot for SharePoint. Data is loaded on Power Pivot for SharePoint instances where it can be refreshed at scheduled intervals using the Power Pivot data refresh capability.

IMPORTANT

SQL Server Analysis Services Power Pivot mode remains supported for SharePoint 2016 and SharePoint 2013. However, Microsoft's BI strategy has shifted away from Power Pivot in Excel integration with SharePoint. [Power BI](#) and [Power BI Report Server](#) are now the recommended platforms to host Excel workbooks with Power Pivot models.

Power Pivot for SharePoint 2019

Support for Power Pivot Gallery and Refresh was removed from SharePoint Server 2019, effectively ending Analysis Services Power Pivot for SharePoint support for SharePoint 2019 and later. To learn more, see [What's deprecated or removed from SharePoint Server 2019](#).

Power Pivot for SharePoint 2016

SQL Server 2019, 2017, 2016 Analysis Services Power Pivot mode supports SharePoint 2016 and Office Online Server usage of Excel workbooks containing data models and Reporting Services Power View reports.

Excel, within Office Online Server includes data model functionality to enable interaction with a Power Pivot workbook in the browser. You do not need to deploy the Power Pivot for SharePoint 2016 add-in into the farm. You only need to install an Analysis Services server in Power Pivot mode and register the server with Office Online Server.

Deploying the Power Pivot for SharePoint 2016 add-in enables additional functionality and features in your SharePoint farm. The additional features include Power Pivot Gallery and Schedule Data Refresh.

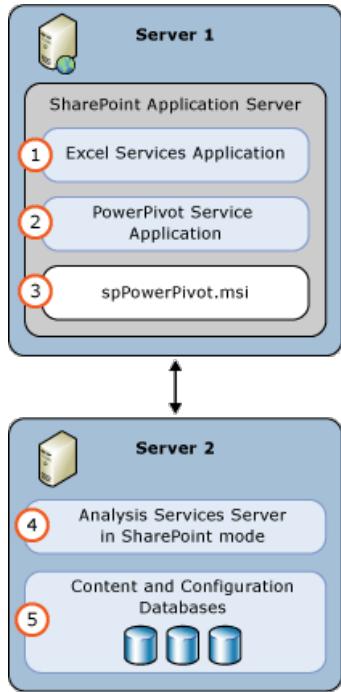

Power Pivot for SharePoint 2013

SQL Server 2019, 2017, 2016 Analysis Services Power Pivot mode supports Microsoft SharePoint 2013 Excel Services usage of Excel workbooks containing data models and Reporting Services Power View reports.

Excel Services in SharePoint 2013 includes data model functionality to enable interaction with a Power Pivot workbook in the browser. You do not need to deploy the Power Pivot for SharePoint 2013 add-in into the farm. You only need to install an Analysis Services server in SharePoint mode and register the server within the Excel Services **Data Model** settings.

Deploying the Power Pivot for SharePoint 2013 add-in enables additional functionality and features in your SharePoint farm. The additional features include Power Pivot Gallery, Schedule Data Refresh, and the Power Pivot Management Dashboard.

Installation and configuration

To learn more about installation and configuration, see [Install Analysis Services in Power Pivot Mode](#). Additional Power Pivot for SharePoint documentation common to all versions going back to SharePoint 2010 is available in the [SQL Server 2014 Analysis Services documentation](#).

Tools for Analysis Services

10/22/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Find the tools and applications you'll need for building Analysis Services models and managing deployed databases.

Create and deploy models

Tabular and multidimensional model projects are created by using project templates in Visual Studio with Analysis Services projects extensions (VSIX). Project templates provide model designers and wizards for creating the data model objects that comprise an Analysis Services solution. Analysis Services projects extensions are supported on all Visual Studio 2017 and later editions, including the free Community edition.

[Download Visual Studio](#)

[Download Analysis Services projects extension](#)

SQL Server Data Tools (SSDT) has been an integral part of creating Analysis Services solutions since SQL 2005. With the introduction of project extensions in Visual Studio, SSDT has been phased out in favor of Visual Studio with Analysis Services projects. Much of the Analysis Services documentation here refers to SSDT, and images often show SSDT windows and dialogs. While Visual Studio 2017 and later with Analysis Services extensions are installed differently and offer even more functionality, the user interface in Visual Studio is much the same as SSDT. Documentation will be updated with new naming and images over time.

Administer servers and databases

Azure portal

The [Azure portal](#) is the primary tool for creating and managing Azure Analysis Services resources. To learn more about the portal and other tools used with Azure Analysis Services, see [Azure Analysis Services tools](#).

SQL Server Management Studio

SQL Server Management Studio (SSMS) is the primary administration tool for Azure Analysis Services and SQL Server Analysis Services servers and deployed model databases. SSMS is a free web download updated monthly.

[Download SQL Server Management Studio](#)

SQL Server Profiler

[SQL Server Profiler](#), installed with SSMS, is a graphical user interface to SQL Trace for monitoring a server instance. You can capture and save data about each event to a file or table to analyze later.

XEvents

SSMS includes extended events (xEvents), providing a lightweight alternative to SQL Server Profiler traces used for monitoring activity and diagnosing problems on Analysis Services servers. See [Monitor Analysis Services with SQL Server Extended Events](#) to learn more.

PowerShell

PowerShell commands are used to perform many database administrative tasks in both Azure Analysis Services and SQL Server Analysis Services. To learn more, see [PowerShell reference](#).

Azure Analysis Services has its own set of PowerShell commands for managing Azure resources. To learn more, see [Manage Azure Analysis Services with PowerShell](#).

Comparing tabular and multidimensional solutions

10/22/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

SQL Server Analysis Services provides several approaches for creating a business intelligence semantic model: Tabular, Multidimensional, and Power Pivot for SharePoint.

Having more than one approach enables a modeling experience tailored to different business and user requirements. Multidimensional is a mature technology built on open standards, embraced by numerous vendors of BI software, but can be hard to master. Tabular offers a relational modeling approach that many developers find more intuitive. Power Pivot is even simpler, offering visual data modeling in Excel, with server support provided via SharePoint.

All models are deployed as databases that run on an Analysis Services instance, accessed by client tools using a single set of data providers, and visualized in interactive and static reports via Excel, Reporting Services, Power BI, and BI tools from other vendors.

Tabular and multidimensional solutions are built using Visual Studio and are intended for corporate BI projects that run on a standalone Analysis Services instance on-premises, and for tabular models, an [Azure Analysis Services](#) server in the cloud. Both solutions yield high performance analytical databases that integrate easily with BI clients. Yet each solution differs in how they are created, used, and deployed. The bulk of this topic compares these two types so that you can identify the right approach for you.

For new projects, we generally recommend tabular models. Tabular models are faster to design, test, and deploy; and will work better with the latest self-service BI applications and cloud services from Microsoft.

Overview of modeling types

New to Analysis Services? The following table enumerates the different models, summarizes the approach, and identifies the initial release vehicle.

NOTE

Azure Analysis Services supports tabular models at the 1200 and higher compatibility levels. However, not all tabular modeling functionality described in this topic is supported in Azure Analysis Services. While creating and deploying tabular models to Azure Analysis Services is much the same as it is for on-premises, it's important to understand the differences. To learn more , see [What is Azure Analysis Services?](#)

| Type | Modeling description | Released |
|---------|--|---|
| Tabular | Relational modeling constructs (model, tables, columns). Internally, metadata is inherited from OLAP modeling constructs (cubes, dimensions, measures). Code and script use OLAP metadata. | SQL Server 2012 and later (compatibility levels 1050 - 1103) ¹ |

| | | |
|----------------------------|---|--|
| Tabular in SQL Server 2016 | Relational modeling constructs (model, tables, columns), articulated in tabular metadata object definitions in Tabular Model Scripting Language (TMSL) and Tabular Object Model (TOM) code. | SQL Server 2016 (compatibility level 1200) |
| Tabular in SQL Server 2017 | Relational modeling constructs (model, tables, columns), articulated in tabular metadata object definitions in Tabular Model Scripting Language (TMSL) and Tabular Object Model (TOM) code. | SQL Server 2017 (compatibility level 1400) |
| Multidimensional | OLAP modeling constructs (cubes, dimensions, measures). | SQL Server 2000 and later |
| Power Pivot | Originally an add-in, but now fully integrated into Excel. Visual modeling only, over an internal Tabular infrastructure. You can import a Power Pivot model into Visual Studio to create a new Tabular model that runs on an Analysis Services instance. | via Excel and Power Pivot BI Desktop |

¹ Compatibility levels are significant in the current release due to tabular metadata engine and support for scenario-enabling features available only at the higher level. Later versions support earlier compatibility levels, but it is recommended you create new models or upgrade existing models to the highest compatibility level supported by the server version.

Model Features

The following table summarizes feature availability at the model level. Review this list to ensure that the feature you want to use is available in the type of model you plan to build.

| | Multidimensional | Tabular |
|---------------------|------------------|------------------|
| Actions | Yes | No |
| Aggregations | Yes | No |
| Calculated Column | No | Yes |
| Calculated Measures | Yes | Yes |
| Calculated Tables | No | Yes ¹ |
| Custom Assemblies | Yes | No |
| Custom Rollups | Yes | No |
| Default Member | Yes | No |
| Display folders | Yes | Yes ¹ |

| | | |
|----------------------------|-----|--|
| Distinct Count | Yes | Yes (via DAX) |
| Drillthrough | Yes | Yes (depends on client application) |
| Hierarchies | Yes | Yes |
| KPIs | Yes | Yes |
| Linked objects | Yes | Yes (linked tables) |
| M expressions | No | Yes ¹ |
| Many-to-many relationships | Yes | No (but there is bi-directional cross filters at 1200 and higher compatibility levels) |
| Named sets | Yes | No |
| Ragged Hierarchies | Yes | Yes ¹ |
| Parent-child Hierarchies | Yes | Yes (via DAX) |
| Partitions | Yes | Yes |
| Perspectives | Yes | Yes |
| Row-level Security | Yes | Yes |
| Object-level Security | Yes | Yes ¹ |
| Semi-additive Measures | Yes | Yes |
| Translations | Yes | Yes |
| User-defined Hierarchies | Yes | Yes |
| Writeback | Yes | No |

¹ See [Compatibility Level for Tabular models in Analysis Services](#) for information about functional differences between compatibility levels.

Data Considerations

Tabular and multidimensional models use imported data from external sources. The amount and type of data you need to import can be a primary consideration when deciding which model type best fits your data.

Compression

Both tabular and multidimensional solutions use data compression that reduces the size of the Analysis Services database relative to the data warehouse from which you are importing data. Because actual compression will vary based on the characteristics of the underlying data, there is no way to know precisely how much disk and memory will be required by a solution after data is processed and used in queries.

An estimate used by many Analysis Services developers is that primary storage of a multidimensional database will be about one third size of the original data. Tabular databases can sometimes get greater amounts of compression, about one tenth the size, especially if most of the data is imported from fact tables.

Size of the model and resource bias (in-memory or disk)

The size of an Analysis Services database is constrained only by the resources available to run it. The model type and storage mode will also play a role in how large the database can grow.

Tabular databases run either in-memory or in DirectQuery mode that offloads query execution to an external database. For tabular in-memory analytics, the database is stored entirely in memory, which means you must have sufficient memory to not only load all the data, but also additional data structures created to support queries.

DirectQuery, revamped in SQL Server 2016, has fewer restrictions than before, and better performance.

Leveraging the backend relational database for storage and query execution makes building a large scale Tabular model more feasible than was previously possible.

Historically, the largest databases in production are multidimensional, with processing and query workloads running independently on dedicated hardware, each one optimized for its respective use. Tabular databases are catching up quickly, and new advancements in DirectQuery will help close the gap even further.

For multidimensional offloading data storage and query execution is available via ROLAP. On a query server, rowsets can be cached, and stale ones paged out. Efficient and balanced use of memory and disk resources often guide customers to multidimensional solutions.

Under load, both disk and memory requirements for either solution type can be expected to increase as Analysis Services caches, stores, scans, and queries data. For more information about memory paging options, see [Memory Properties](#). To learn more about scale, see [High availability and Scalability in Analysis Services](#).

Power Pivot for Excel has an artificial file size limit of 2 gigabytes, which is imposed so that workbooks created in Power Pivot for Excel can be uploaded to SharePoint, which sets maximum limits on file upload size. One of the main reasons for migrating a Power Pivot workbook to a tabular solution on a standalone Analysis Services instance is to get around the file size limitation. For more information about configuring maximum file upload size, see [Configure Maximum File Upload Size \(Power Pivot for SharePoint\)](#).

Supported Data Sources

Tabular models can import data from relational data sources, data feeds, and some document formats. You can also use OLE DB for ODBC providers with tabular models. Tabular models at the 1400 compatibility level offer a significant increase in the variety of data sources from which you can import from. This is due to the introduction of the modern Get Data data query and import features in Visual Studio utilizing the M formula query language.

Multidimensional solutions can import data from relational data sources using OLE DB native and managed providers.

To view the list of external data sources that you can import to each model, see the following topics:

- [Data Sources Supported](#)
- [Supported Data Sources \(SSAS - Multidimensional\)](#)

Query and Scripting Language Support

Analysis Services includes MDX, DMX, DAX, XML/A, ASSL, and TMSL. Support for these languages can vary by model type. If query and scripting language requirements are a consideration, review the following list.

- Tabular model databases support DAX calculations, DAX queries, and MDX queries. This is true at all compatibilities levels. Script languages are ASSL (over XMLA) for compatibility levels 1050-1103, and TMSL (over XMLA) for compatibility level 1200 and higher.

- Power Pivot workbooks use DAX for calculations, and DAX or MDX for queries.
- Multidimensional model databases support MDX calculations, MDX queries, DAX queries, and ASSL.
- Data mining models support DMX and ASSL.
- Analysis Services PowerShell is supported for Tabular and Multidimensional models and databases.

All databases support XML/A.

Security Features

All Analysis Services solutions can be secured at the database level. More granular security options vary by mode. If granular security settings are requirement for your solution, review the following list to ensure the level of security you want is supported in the type of solution you want to build:

- Tabular model databases can use row-level security, using role-based permissions.
- Multidimensional model databases can use dimension and cell-level security, using role-based permissions.
- Power Pivot workbooks are secured at the file level, using SharePoint permissions.

Power Pivot workbooks can be restored to a Tabular mode server. Once the file is restored, it is decoupled from SharePoint, allowing you to use all tabular modeling features, including row-level security.

Design Tools

Data modeling skills and technical expertise can vary widely among users who are tasked with building analytical models. If tool familiarity or user expertise is a consideration for your solution, compare the following experiences for model creation.

| MODELING TOOL | HOW USED |
|---|--|
| Visual Studio with Analysis Services projects | Use to create tabular, multidimensional, and data mining solutions. This authoring environment uses the Visual Studio shell to provide workspaces, property panes, and object navigation. Technical users who already use Visual Studio will most likely prefer this tool for building business intelligence applications. |
| Power Pivot for Excel | Use to create a Power Pivot workbook that you later deploy to a SharePoint farm that has an installation of Power Pivot for SharePoint. Power Pivot for Excel has a separate application workspace that opens over Excel. It uses the same visual metaphors (tabbed pages, grid layout, and formula bar) as Excel. Users who are proficient in Excel will prefer this tool over Visual Studio with Analysis Services projects. |

Client Application Support

In-general, tabular and multidimensional solutions support client applications using one or more of the Analysis Services client libraries (MSOLAP, AMOMD, ADOMD). For example, Excel, Power BI Desktop, and custom applications.

If you are using Reporting Services, report feature availability varies across editions and server modes. For this reason, the type of report that you want to build might influence which server mode you choose to install.

Power View, a Reporting Services authoring tool that runs in SharePoint, is available on a report server that is deployed in a SharePoint 2010 farm. The only type of data source that can be used with this report is an Analysis

Services tabular model database or a Power Pivot workbook. This means that you must have a tabular mode server or a Power Pivot for SharePoint server to host the data source used by this type of report. You cannot use a multidimensional model as a data source for a Power View report. You must create a Power Pivot BI Semantic Model connection or a Reporting Services shared data source to use as the data source for a Power View report.

Report Builder and Report Designer can use any Analysis Services database, including Power Pivot workbooks that are hosted on Power Pivot for SharePoint.

Excel PivotTable reports are supported by all Analysis Services databases. Excel functionality is the same whether you use a tabular .database, multidimensional database, or Power Pivot workbook, although Writeback is only supported for multidimensional databases.

Globalization scenarios for Analysis Services

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Analysis Services stores and manipulates multilingual data and metadata for both tabular and multidimensional data models. Data storage is Unicode (UTF-16), in character sets that use Unicode encoding. If you load ANSI data into a data model, characters are stored using Unicode equivalent code points.

The implications of Unicode support means that Analysis Services can store data in any of the languages supported by the Windows client and server operating systems, allowing read, write, sort, and comparison of data in any character set used on a Windows computer. BI client applications consuming Analysis Services data can represent data in the user's language of choice, assuming the data exists in that language in the model.

Language support can mean different things to different people. The following list addresses a few common questions related to how Analysis Services supports languages.

- Data, as already noted, is stored in any Unicode-encoded character set found on a Windows client operating system.
- Metadata, such as object names, can be translated. Although support varies by model type, both multidimensional and tabular models support the addition of translated strings inside the model. You can define multiple translations, and then use a locale identifier to determine which translation is returned to the client. See [Features](#) below for more details
- Error, warning, and informational messages returned by the Analysis Services engine (msmdsrv) are localized into the 43 languages supported by Office and Office 365. No configuration is required to get messages in a specific language. The locale of the client application determines which strings are returned.
- Configuration file (msmdsrv.ini) and AMO PowerShell are in English only.
- Log files will contain a mix of English and localized messages, assuming you have installed a language pack on the Windows server that Analysis Services runs on.
- Documentation and tools, such as Management Studio and Visual Studio with Analysis Services projects, are translated into these languages: Chinese Simplified, Chinese Traditional, French, German, Italian, Japanese, Korean, Portuguese (Brazil), Russian, and Spanish. Culture is specified during installation.

For multidimensional models, Analysis Services lets you set language, collation, and translations independently throughout the object hierarchy. For tabular models, you can only add translations: language and collation are inherited by the host operating system.

Scenarios enabled through Analysis Services globalization features include:

- One data model provides multiple translated captions so that field names and values appear in the user's language of choice. For companies operating in bi-lingual countries such as Canada, Belgium, or Switzerland, supporting multiple languages across client and server applications is a standard coding requirement. This scenario is enabled through translations and currency conversions. See [Features](#) below for details and links.
- Development and production environments are geo-located in different countries. It's increasingly common to develop a solution in one country and then deploy it another. Knowing how to set language and collation properties is essential if you are tasked with preparing a solution developed in one language, for deployment on a server that uses a different language pack. Setting these properties allows you to

override the inherited defaults that you get from the original host system. See [Languages and Collations \(Analysis Services\)](#) for details about setting properties.

Features for building a globalized multi-lingual solution

At the client level, globalized applications that consume or manipulate Analysis Services multidimensional data can use the multilingual and multicultural features in Analysis Services.

You can retrieve data and metadata from Analysis Services objects on which translations have been defined automatically by providing a locale identifier when connecting to an Analysis Services instance.

See [Globalization Tips and Best Practices \(Analysis Services\)](#) for design and coding practices that can help you avoid problems related to multi-language data.

| Capability | Tabular | Multidimensional |
|--|---|--|
| Languages and Collations (Analysis Services) | Inherited from the operating system. | Inherited, but with the ability to override both language and collation for major objects in the model hierarchy. |
| Scope of translation support | Captions and descriptions. | Translations can be created for object names, captions, identifiers, and descriptions, can also be in any Unicode language and script. This is true even when the tools and environment are in another language. For example, in a development environment that uses English language and a Latin collation throughout the stack, you can include in your model an object that uses Cyrillic characters in its name. |
| Implementing translation support | Create using Visual Studio with Analysis Services projects to generate translation files that you fill in and then import back into the model.

See Translations in Tabular models (Analysis Services) for details. | Create using Visual Studio with Analysis Services projects to define the translations for the caption, description, and account types for cubes and measures, dimension and attributes.

See Translations in Multidimensional Models (Analysis Services) for more information. |
| Currency conversion | Not available. | Currency conversion is through specialized MDX scripts that convert measures containing currency data. You can use the Business Intelligence Wizard in SQL Server Data Tools - Business Intelligence to generate an MDX script that uses a combination of data and metadata from dimensions, attributes, and measure groups to convert measures containing currency data. See Currency Conversions (Analysis Services) . |

Languages and Collations (Analysis Services)

9/6/2019 • 13 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Analysis Services supports the languages and collations provided by Microsoft Windows operating systems.

Language and **Collation** properties are initially set at the instance level during installation, but can be changed afterwards at different levels of the object hierarchy.

In a multidimensional model (only), you can set these properties on a database or cube - you can also set them on translations that you create for objects within a cube. In a tabular model, language and collation are inherited from the host operating system.

When setting **Language** and **Collation** in a multidimensional model, you are either specifying settings used by the data model during processing and query execution, or you are equipping a model with multiple translations so that foreign language speakers can work with the model in their native language. Explicitly setting **Language** and **Collation** properties on an object (database, model, or cube) is for situations where the development environment and production server are configured for different locales, and you want to be sure that the language and collation matches those of the intended target environment.

Objects that support Language and Collation properties

Language and **Collation** properties are often exposed together - where you can set **Language**, you can also set **Collation**.

You can set **Language** and **Collation** on these objects:

- **Instance.** All projects deployed to the instance will adopt the language and collation of the instance, assuming the language and collation are undefined. By default, a multidimensional model leaves language and collation empty. When the project is deployed, the resulting database and cubes get the language and collation of the instance.

Initially, language and collation properties are established during setup but an administrator can override them in Management Studio. See [Change the default language or collation on the instance](#) for details.

- **Database.** To break inheritance, you can explicitly set language and collation at the project level that is used by all cubes contained in the database. Unless you indicate otherwise, all cubes in the database will get the language and collation you specify at this level. If you routinely code and deploy to different locales (for example, developing the solution on a Chinese computer, but deploying it to a server owned by a French subsidiary), setting language and collation at the database level is the first and most important step to ensuring the solution works in the target environment. The best place to set these properties is inside the project (via the **Edit Database** command on the project).
- **Database dimension.** Although the designer exposes **Language** and **Collation** properties on a database dimension, setting properties on this object is not useful. Database dimensions are not used as standalone objects, so it could be difficult if not impossible to make use of the properties you define. When in a cube, a dimension always inherits **Language** and **Collation** from its cube parent. Any values you might have set on the standalone database dimension object are ignored.
- **Cube.** As the primary query structure, you can set language and collation at the cube level. For example, you might want to create multiple language versions of a cube, such as English and Chinese versions, within the same project, where each cube has its own language and collation.

Whatever language and collation you set on the cube is used by all measures and dimensions contained in the cube. The only way to set collation properties at a finer grain is if you are creating translations on a dimension attribute. Otherwise, assuming no translations at the attribute level, there is one collation per cube.

Additionally, you can set **Language**, by itself, on a **Translation** object.

A translation object is created when you add translations to a cube or dimension. **Language** is part of the translation definition. **Collation**, on the other hand, is set on the cube or higher, and shared by all translations. This is evident in the XMLA of a cube containing translations, where you will see multiple language properties (one for each translation), but only one collation. Note that there is one exception for dimension attribute translations, where you can override cube collation to specify an attribute collation that matches the source column (the database engine supports setting collation on individual columns, and it's common to configure individual translations to obtain member data from different source columns). But otherwise, for all other translations, **Language** is used by itself, without a **Collation** corollary. See [Translation support in Analysis Services](#) for details.

Language support in Analysis Services

The **Language** property sets the locale of an object, used during processing, queries, and with **Captions** and **Translations** to support multi-lingual scenarios. Locales are based on a language identifier, such as English, and a territory, such as United States or Australia, that further refines date and time representations.

At the instance level, the property is set during installation and is based on the language of the Windows server operating system (one of 37 languages, assuming a language pack is installed). You cannot change the language in Setup.

Post-installation, you can override **Language** using the server properties page in Management Studio, or in the msmdsrv.ini configuration file. You can choose from many more languages, including all those supported by the Windows client. When set at the instance level, on the server, **Language** determines the locale of all databases that are subsequently deployed. For example, if you set **Language** to German, all databases that are deployed to the instance will have a Language property of 1031, the LCID for German.

Value of the **Language** property is a Locale Identifier (LCID)

Valid values include any LCID that appears in the drop-down list. In Management Studio and SQL Server Data Tools, LCIDs are represented in string equivalents. The same languages show up wherever the **Language** property is exposed, regardless of the tool. Having an identical list of languages ensures that you can implement and test translations consistently throughout the model.

Although Analysis Services lists the languages by name, the actual value stored for the property is an LCID. When setting a language property programmatically or through the msmdsrv.ini file, use the [locale identifier \(LCID\)](#) as the value. An LCID is a 32-bit value consisting of a language ID, sort ID, and reserved bits that identify a particular language. Analysis Services uses LCIDs to specify the selected language for Analysis Services instances and objects.

You can set the LCID using either hexadecimal or decimal formats. A few examples of valid values for the **Language** property include:

- 0x0409 or 1033 for **English (United States)**
- 0x0411 or 1041 for **Japanese**
- 0x0407 or 1031 for **Germany (German)**
- 0x0416 or 1046 for **Portuguese (Brazil)**.

To view a longer list, see [Locale IDs Assigned by Microsoft](#). For more background, see [Encoding and Code Pages](#).

NOTE

The **Language** property does not determine the language for returning system messages, or which strings appear in the user interface. Errors, warnings, and messages are localized into all languages supported in Office and Office 365 and are used automatically when the client connection specifies one of the supported locales.

Collation support in Analysis Services

Analysis Services uses Windows (versions _90 and _100) and binary collations exclusively. It does not use legacy SQL Server collations. Within a cube, a single collation is used throughout, with the exception of translations at the attribute level. For more information about defining attribute translations, see [Translation support in Analysis Services](#).

Collations control the case-sensitivity of all strings in a bicameral language script, with the exception of object identifiers. If you use upper and lower case characters in an object identifier, be forewarned that the case-sensitivity of object identifiers is determined not by the collation, but by Analysis Services. For object identifiers composed in English script, object identifiers are always case-insensitive, regardless of collation. Cyrillic and other bicameral languages do the opposite (always case-sensitive). See [Globalization Tips and Best Practices \(Analysis Services\)](#) for details.

Collation in Analysis Services is compatible with that of the SQL Server relational database engine, assuming you maintain parity in the sort options you select for each service. For example, if the relational database is accent sensitive, you should configure the cube the same way. Problems can occur when collations settings diverge. For an example and workarounds, see [Blanks in a Unicode string have different processing outcomes based on collation](#). To learn more about collation and the database engine, see [Collation and Unicode Support](#).

Collation Types

Analysis Services supports two collation types:

- **Windows collations (versions _90 and _100)**

Windows collation versions are _90 (an unmarked older version) and the newer _100 version. Only the _100 version shows the version number in the collation name:

- latin1_general
- latin1_general_100

A Windows collation sorts characters based on the linguistic and cultural characteristics of the language. In Windows, collations outnumber the locales (or languages) used with them, due to many languages sharing common alphabets and rules for sorting and comparing characters. For example, 33 Windows locales, including all the Portuguese and English Windows locales, use the Latin1 code page (1252) and follow a common set of rules for sorting and comparing characters.

NOTE

When deciding on a collation, you should go with the same collation used by the underlying database. However, if you can choose, the _100 version is more up-to-date and offers a more linguistically accurate cultural sorting convention.

- **Binary collations (either BIN or BIN2)**

Binary collations sort on Unicode code points, not on linguistic values. For example, Latin1_General_BIN and Japanese_BIN yield identical sorting results when used on Unicode data. Whereas a linguistic sort might yield results like aAbBcCdD, a binary sort would be ABCDabcd because the code point of all

uppercase characters is collectively higher than the code points of the lowercase characters.

Sort Order Options

Sort options are used to refine sorting and comparison rules based on case, accent, kana, and width sensitivity. For example, the default value of the **Collation** configuration property for Analysis Services is Latin1_General_AS_CS, specifying that the Latin1_General collation is used, with an accent-sensitive, case-sensitive sort order.

Note that BIN and BIN2 are mutually exclusive of other sort options, if you want to use BIN or BIN2, clear the sort option for Accent Sensitive. Similarly, when BIN2 is selected, the case-sensitive, case-insensitive, accent-sensitive, accent-insensitive, kana-sensitive, and width-sensitive options are not available.

The following table describes Windows collation sort order options and associated suffixes for Analysis Services.

| SORT ORDER (SUFFIX) | SORT ORDER DESCRIPTION |
|-------------------------------|---|
| Binary (_BIN) or BIN2 (_BIN2) | <p>There are two types of binary collations in SQL Server; the older BIN collations and the newer BIN2 collations. In a BIN collation all characters are sorted according to their code points. In a BIN collation only the first character is sorted according to the code point, and remaining characters are sorted according to their byte values. (Because the Intel platform is a little endian architecture, Unicode code characters are always stored byte-swapped.)</p> <p>For binary collations on Unicode data types, the locale is not considered in data sorts. For example, Latin_1_General_BIN and Japanese_BIN yield identical sorting results when they are used on Unicode data.</p> <p>Binary sort order is case sensitive and accent sensitive. Binary is also the fastest sorting order.</p> |
| Case-sensitive (_CS) | <p>Distinguishes between uppercase and lowercase letters. If selected, lowercase letters sort ahead of their uppercase versions. You can explicitly set case-insensitivity by specifying _CI. Collation-specific case settings do not apply to object identifiers, such as the ID of a dimension, cube, and other objects. See Globalization Tips and Best Practices (Analysis Services) for details.</p> |
| Accent-sensitive (_AS) | <p>Distinguishes between accented and unaccented characters. For example, 'a' is not equal to 'á'. If this option is not selected, Analysis Services considers the accented and unaccented versions of letters to be identical for sorting purposes. You can explicitly set accent-insensitivity by specifying _AI.</p> |
| Kana-sensitive (_KS) | <p>Distinguishes between the two types of Japanese kana characters: hiragana and katakana. If this option is not selected, Analysis Services considers hiragana and katakana characters to be equal for sorting purposes. There is no sort order suffix for kana-insensitive sorting.</p> |
| Width-sensitive (_WS) | <p>Distinguishes between a single-byte character and the same character when represented as a double-byte character. If this option is not selected, Analysis Services considers the single-byte and double-byte representation of the same character to be identical for sorting purposes. There is no sort order suffix for width-insensitive sorting.</p> |

Change the default language or collation on the instance

Default language and collation is established during setup, but can be changed as part of post-installation configuration. Changing the collation at the instance level is non-trivial and comes with these requirements:

- A service restart.
- Update the collation settings of existing objects. Collation settings are inherited once when the object is created. Subsequent changes to collation must be done manually. See [Change language and collation within a data model using XMLA](#) for tips on how to propagate collation changes throughout the model.
- Reprocess partitions and dimensions after the collation is updated.

You can use SQL Server Management Studio or AMO PowerShell to change the default language or collation at the server level. Alternatively, you can modify the <Language> and <CollationName> settings in the msmdsrv.ini file, specifying the LCID of the language.

1. In Management Studio, right-click server name | **Properties** | **Language/Collation**.
2. Choose the sort options. To select either **Binary** or **Binary 2**, first clear the checkbox for **Accent Sensitive**.

Note that collation and language are fully independent settings. If you change one, the values of the other are not filtered to show common combinations.

3. Update the data model to use the new collation (see the following section).
4. Restart the service.

Change the language or collation on a cube

1. In Solution Explorer, double-click the cube to open it in cube designer.
2. In either the Measures or Dimensions pane, select the top node. The top-level object for either pane is the cube.
3. In Properties, set **Language** and **Collation**. The values you choose will be used by all cube objects, including cube dimensions and measures, and affects processing and query operations.

The only way to embed alternate language and collation properties on objects within the cube is through translations. See [Translation support in Analysis Services](#) for details.

Change language and collation within a data model using XMLA

Language and collation settings are inherited once when the object is created. Subsequent changes to those properties must be done manually. One approach for changing collation multiple objects quickly is to use an ALTER command on an XMLA script.

By default, collation is set once, at the database level. Inheritance is implied throughout the rest of the object hierarchy. If you explicitly set **Collation** on objects within the cube, which is allowed on individual dimension attributes, it will appear in the XMLA definition. Otherwise, only the top-level collation property exists.

Before using XMLA to modify an existing database, make sure that you're not introducing discrepancies between the database and the source files used to build it. For example, you might want to use XMLA to quickly change language or collation for proof-of-concept testing, but then follow-up with changes to the source file (see [Change the language or collation on a cube](#)), redeploying the solution using the existing operating procedures already in place.

1. In Management Studio, right-click the database | **Script Database as** | **ALTER To** | **New Query Editor Window**.

2. Search and replace the existing language or collation with an alternative value.
3. Press F5 to execute the script.
4. Reprocess the cube.

Boost performance for English locales through EnableFast1033Locale

If you use the English (United States) language identifier (0x0409, or 1033) as the default language for the Analysis Services instance, you can get additional performance benefits by setting the **EnableFast1033Locale** configuration property, an advanced configuration property available only for that language identifier. Setting the value of this property to **true** enables Analysis Services to use a faster algorithm for string hashing and comparison. For more information about setting configuration properties, see [Server properties in Analysis Services](#).

GB18030 Support in Analysis Services

GB18030 is a separate standard used in the People's Republic of China for encoding Chinese characters. In GB18030, characters can be 1, 2, or 4 bytes in length. In Analysis Services, there is no data conversion when processing data from external sources. The data is simply stored as Unicode. At query time, a GB18030 conversion is performed through the Analysis Services client libraries (specifically, the MSOLAP.dll OLE DB provider) when text data is returned in query results, based on the client OS settings. The database engine also supports GB18030. For details, see [Collation and Unicode Support](#).

Translation support in Analysis Services

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Analysis Services data models, you can embed multiple translations of a caption or description to provide culture-specific strings based on the locale identifier (LCID). For multidimensional models, translations can be added for the database name, cube objects, and database dimension objects. For tabular models, you can translate table and column captions and descriptions.

Defining a translation creates the metadata and translated caption inside the model, but to render localized strings in a client application, you must either set the **Language** property on the object, or pass a **Culture** or **Locale Identifier** parameter on the connection string (for example, by setting `LocaleIdentifier=1036` to return French strings).

Plan on using **Locale Identifier** if you want to support multiple, simultaneous translations of the same object in different languages. Setting the **Language** property works, but it also impacts processing and queries, which could have unintended consequences. Setting **Locale Identifier** is the better choice because it's only used to return translated strings.

A translation consists of a locale identifier (LCID), a translated caption for the object (for example, the dimension or attribute name), and optionally, a binding to a column that provides data values in the target language. You can have multiple translations, but you can only use one for any given connection. There is no theoretical limit on the number of translations you can embed in model, but each translation adds complexity to testing, and all translations must share the same collation, so when designing your solution keep these natural constraints in mind.

TIP

You can use client applications such as Excel, SQL Server Management Studio, and SQL Server Profiler to return translated strings. See [Globalization Tips and Best Practices \(Analysis Services\)](#) for details.

How to add translated metadata to model in Analysis Services

Currency conversions in Analysis Services

7/16/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Analysis Services uses a combination of features, guided by Multidimensional Expressions (MDX) scripts, to provide currency conversion support in cubes supporting multiple currencies.

Currency conversion terminology

The following terminology is used to describe currency conversion functionality:

Pivot currency - Is the currency against which exchange rates are entered in the rate measure group.

Local currency - Is the currency used to store transactions on which measures to be converted are based.

Local currency can be identified by either:

- A currency identifier in the fact table stored with the transaction, as is commonly the case with banking applications where the transaction itself identifies the currency used for that transaction.
- A currency identifier associated with an attribute in a dimension table that is then associated with a transaction in the fact table, as is commonly the case in financial applications where a location or other identifier, such as a subsidiary, identifies the currency used for an associated transaction.

Reporting currency - Is the currency to which transactions are converted from the pivot currency.

NOTE

For many-to-one currency conversions, the pivot currency and reporting currency are the same.

Currency dimension - A database dimension defined with the following settings:

- The **Type** property of the dimension is set to Currency.
- The **Type** property of one attribute for the dimension is set to CurrencyName.

The values of this attribute must be used in all columns that should contain a currency identifier.

Rate measure group - A measure group in a cube, defined with the following settings:

- A regular dimension relationship exists between a currency dimension and the rate measure group.
- A regular dimension relationship exists between a time dimension and the rate measure group.
- Optionally, the **Type** property is set to ExchangeRate. While the Business Intelligence Wizard uses the relationships with the currency and time dimensions to identify likely rate measure groups, setting the **Type** property to ExchangeRate allows client applications to more easily identify rate measure groups.
- One or more measures, representing the exchange rates contained by the rate measure group.

Reporting currency dimension - Is the dimension, defined by the Business Intelligence Wizard after a currency conversion is defined, that contains the reporting currencies for that currency conversion. The reporting currency dimension is based on a named query, defined in the data source view on which the currency dimension associated with the rate measure group is based, from the dimension main table of the currency dimension. The

dimension is defined with the following settings:

- The **Type** property of the dimension is set to Currency.
- The **Type** property of the key attribute for the dimension is set to CurrencyName.
- The **Type** property of one attribute within the dimension is set to CurrencyDestination, and the column bound to the attribute contains the currency identifiers that represent the reporting currencies for the currency conversion.

Defining currency conversions

You can use the Business Intelligence Wizard to define currency conversion functionality for a cube, or you can manually define currency conversions using MDX scripts.

Prerequisites

Before you can define a currency conversion in a cube using the Business Intelligence Wizard, you must first define at least one currency dimension, at least one time dimension, and at least one rate measure group. From these objects, the Business Intelligence Wizard can retrieve the data and metadata used to construct the reporting currency dimension and MDX script needed to provide currency conversion functionality.

Decisions

You need to make the following decisions before the Business Intelligence Wizard can construct the reporting currency dimension and MDX script needed to provide currency conversion functionality:

- Exchange rate direction
- Converted members
- Conversion type
- Local currencies
- Reporting currencies

Exchange rate directions

The rate measure group contains measures representing exchange rates between local currencies and the pivot currency (commonly referred to as the corporate currency). The combination of exchange rate direction and conversion type determines the operation performed on measures to be converted by the MDX script generated using the Business Intelligence Wizard. The following table describes the operations performed depending on the exchange rate direction and conversion type, based on the exchange rate direction options and conversion directions available in the Business Intelligence Wizard.

| Exchange rate direction | Many-to-one | One-to-many | Many-to-many |
|--|---|---|--|
| n pivot currency to 1 sample currency | Multiply the measure to be converted by the exchange rate measure for the local currency in order to convert the measure into the pivot currency. | Divide the measure to be converted by the exchange rate measure for the reporting currency in order to convert the measure into the reporting currency. | Multiply the measure to be converted by the exchange rate measure for the local currency in order to convert the measure into the pivot currency, then divide the converted measure by the exchange rate measure for the reporting currency in order to convert the measure into the reporting currency. |

| | | | |
|--|---|---|--|
| n sample currency to 1 pivot currency | Divide the measure to be converted by the exchange rate measure for the local currency in order to convert the measure into the pivot currency. | Multiply the measure to be converted by the exchange rate measure for the reporting currency in order to convert the measure into the reporting currency. | Divide the measure to be converted by the exchange rate measure for the local currency in order to convert the measure into the pivot currency, then multiply the converted measure by the exchange rate measure for the reporting currency in order to convert the measure into the reporting currency. |
|--|---|---|--|

You choose the exchange rate direction on the **Set currency conversion options** page of the Business Intelligence Wizard. For more information about setting conversion direction, see [Set Currency Conversion Options \(Business Intelligence Wizard\)](#).

Converted members

You can use the Business Intelligence Wizard to specify which measures from the rate measure group are used to convert values for:

- Measures in other measure groups.
- Members of an attribute hierarchy for an account attribute in a database dimension.
- Account types, used by members of an attribute hierarchy for an account attribute in a database dimension.

The Business Intelligence Wizard uses this information within the MDX script generated by the wizard to determine the scope of the currency conversion calculation. For more information about specifying members for currency conversion, see [Select Members \(Business Intelligence Wizard\)](#).

Conversion types

The Business Intelligence Wizard supports three different types of currency conversion:

- **One-to-many**

Transactions are stored in the fact table in the pivot currency, and then converted to one or more other reporting currencies.

For example, the pivot currency can be set to United States dollars (USD), and the fact table stores transactions in USD. This conversion type converts these transactions from the pivot currency to the specified reporting currencies. The result is that transactions can be stored in the specified pivot currency and viewed either in the specified pivot currency or in any of the reporting currencies specified in the reporting currency dimension defined for the currency conversion.

- **Many-to-one**

Transactions are stored in the fact table in local currencies, and then converted into the pivot currency. The pivot currency serves as the only specified reporting currency in the reporting currency dimension.

For example, the pivot currency can be set to United States dollars (USD), and the fact table stores transactions in euros (EUR), Australian dollars (AUD), and Mexican pesos (MXN). This conversion type converts these transactions from their specified local currencies to the pivot currency. The result is that transactions can be stored in the specified local currencies and viewed in the pivot currency, which is specified in the reporting currency dimension defined for the currency conversion.

- **Many-to-many**

Transactions are stored in the fact table in local currencies. The currency conversion functionality converts such transactions into the pivot currency, and then to one or more other reporting currencies.

For example, the pivot currency can be set to United States dollars (USD), and the fact table stores transactions in euros (EUR), Australian dollars (AUD), and Mexican pesos (MXN). This conversion type converts these transactions from their specified local currencies to the pivot currency, and then the converted transactions are converted again from the pivot currency to the specified reporting currencies. The result is that transactions can be stored in the specified local currencies and viewed either in the specified pivot currency or in any of the reporting currencies that are specified in the reporting currency dimension defined for the currency conversion.

Specifying the conversion type allows the Business Intelligence Wizard to define the named query and dimension structure of the reporting currency dimension, as well as the structure of the MDX script defined for the currency conversion.

Local currencies

If you choose a many-to-many or many-to-one conversion type for your currency conversion, you need to specify how to identify the local currencies from which the MDX script generated by the Business Intelligence Wizard performs the currency conversion calculations. The local currency for a transaction in a fact table can be identified in one of two ways:

- The measure group contains a regular dimension relationship to the currency dimension. For example, in the Adventure Works DW Multidimensional 2012 sample Analysis Services database, the Internet Sales measure group has a regular dimension relationship to the Currency dimension. The fact table for that measure group contains a foreign key column that references the currency identifiers in the dimension table for that dimension. In this case, you can select the attribute from the currency dimension that is referenced by the measure group to identify the local currency for transactions in the fact table for that measure group. This situation most often occurs in banking applications, where the transaction itself determines the currency used within the transaction.
- The measure group contains a referenced dimension relationship to the currency dimension, through another dimension that directly references the currency dimension. For example, in the Adventure Works DW Multidimensional 2012 sample Analysis Services database, the Financial Reporting measure group has a referenced dimension relationship to the Currency dimension through the Organization dimension. The fact table for that measure group contains a foreign key column that references members in the dimension table for the Organization dimension. The dimension table for the Organization dimension, in turn, contains a foreign key column that references the currency identifiers in the dimension table for the Currency dimension. This situation most often occurs in financial reporting applications, where the location or subsidiary for a transaction determines the currency for the transaction. In this case, you can select the attribute that references the currency dimension from the dimension for the business entity.

Reporting currencies

If you choose a many-to-many or one-to-many conversion type for your currency conversion, you need to specify the reporting currencies for which the MDX script generated by the Business Intelligence Wizard performs the currency conversion calculations. You can either specify all the members of the currency dimension related to the rate measure group, or select individual members from the dimension.

The Business Intelligence Wizard creates a reporting currency dimension, based on a named query constructed from the dimension table for the currency dimension using the selected reporting currencies.

NOTE

If you select the one-to-many conversion type, a reporting currency dimension is also created. The dimension contains only one member representing the pivot currency, because the pivot currency is also used as the reporting currency for a one-to-many currency conversion.

A separate reporting currency dimension is defined for each currency conversion defined in a cube. You can change the name of the reporting currency dimensions after creation, but if you do so you must also update the MDX script generated for that currency conversion to ensure that the correct name is used by the script command when referencing the reporting currency dimension.

Defining multiple currency conversions

Using the Business Intelligence Wizard, you can define as many currency conversions as needed for your business intelligence solution. You can either overwrite an existing currency conversion or append a new currency conversion to the MDX script for a cube. Multiple currency conversions defined in a single cube provide flexibility in business intelligence applications that have complex reporting requirements, such as financial reporting applications that support multiple, separate conversion requirements for international reporting.

Currency conversion in multidimensional models by using Business Intelligence Wizard

The Business Intelligence Wizard identifies each currency conversion by framing the script commands for the currency conversion in the following comments:

```
//<Currency conversion>
```

```
...
```

```
[MDX statements for the currency conversion]
```

```
...
```

```
//</Currency conversion>
```

If you change or remove these comments, the Business Intelligence Wizard is unable to detect the currency conversion, so you should not change these comments.

The wizard also stores metadata in comments within these comments, including the creation date and time, the user, and the conversion type. These comments should also not be changed because the Business Intelligence Wizard uses this metadata when displaying existing currency conversions.

You can change the script commands contained in a currency conversion as needed. If you overwrite the currency conversion, however, your changes will be lost.

Globalization Tips and Best Practices (Analysis Services)

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Applies to: Multidimensional only

These tips and guidelines can help increase the portability of your business intelligence solutions and avoid errors that are directly related to language and collation settings.

Use similar collations throughout the stack

If possible, try to use the same collation settings in Analysis Services that you use for the database engine, striving for correspondence in width-sensitivity and case-sensitivity, and access-sensitivity.

Each service has its own collation settings, with the database engine default set to `SQL_Latin1_General_CI_AS` and Analysis Services set to `Latin1_General_AS`. The defaults are compatible in terms of case, width, and accent sensitivity. Be forewarned that if you vary the settings of either collation, you can run into problems when the collation properties diverge in fundamental ways.

Even when collation settings are functionally equivalent, you can run into a special case where an empty space anywhere within a string is interpreted differently by each service.

The space character is a 'special case' because it can be represented as a single-byte (SBCS) or double-byte character set (DBCS) in Unicode. In the relational engine, two compound strings separated by a space -- one using SBCS, the other in DBCS -- are considered identical. In Analysis Services, during processing, the same two compound strings are not identical, and the second instance will be flagged as a duplicate.

For more details and suggested workarounds, see [Blanks in a Unicode string have different processing outcomes based on collation](#).

Common collation recommendations

Analysis Services always presents the full list of all available languages and collations; it does not filter the collations based on the language you selected. Be sure to choose a workable combination.

Some of the more commonly used collations include those in the following list.

You should consider this list to be a starting point for further investigation, rather than a definitive recommendation that excludes other options. You might find that a collation not specifically recommended is the one that works best for your data. Thorough testing is the only way to verify whether data values are sorted and compared appropriately. As always, be sure to run both processing and query workloads when testing collation.

- Latin1_General_100_AS is often used for applications that use the 26 characters of the [ISO basic Latin alphabet](#).
- North European languages that include Scandinavian letters (such as ø) can use Finnish_Swedish_100.
- East European languages, such as Russian, often use Cyrillic_General_100.
- Chinese language and collations vary by region, but are generally either Chinese Simplified or Chinese Traditional.

In PRC and Singapore, Microsoft Support tends to see Simplified Chinese, with Pinyin as the preferred sort order. The recommended collations are Chinese_PRC (for SQL Server 2000), Chinese_PRC_90 (for SQL Server 2005) or Chinese_Simplified_Pinyin_100 (for SQL Server 2008 and later).

In Taiwan, it is more common to see Traditional Chinese with the recommended sort order is based on Stroke Count: Chinese_Taiwan_Stroke (for SQL Server 2000), Chinese_Taiwan_Stroke_90 (for SQL Server 2005) or Chinese_Traditional_Stroke_Count_100 (for SQL Server 2008 and later).

Other regions (such as Hong Kong and Macau) also use Traditional Chinese. For collations, in Hong Kong, it's not unusual to see Chinese_Hong_Kong_Stroke_90 (on SQL Server 2005). In Macau, Chinese_Traditional_Stroke_Count_100 (on SQL Server 2008 and later) is used fairly often.

- For Japanese, the most commonly used collation is Japanese_CI_AS. Japanese_XJIS_100 is used in installations supporting [JIS2004](#). Japanese_BIN2 is typically seen in data migration projects, with data originating from non-Windows platforms, or from data sources other than the SQL Server relational database engine.

Japanese_Bushu_Kakusu_100 is rarely seen in servers that run Analysis Services workloads.

- Korean_100 is recommended for Korean. Although Korean_Wansung_Unicode is still available in the list, it has been deprecated.

Case sensitivity of object identifiers

Starting in SQL Server 2012 SP2, case sensitivity of object IDs is enforced independently of the collation, but the behavior varies by language:

| LANGUAGE SCRIPT | CASE SENSITIVITY |
|--|--|
| Basic Latin alphabet | <p>Object identifiers expressed in Latin script (any of the 26 English upper or lower case letters) are treated as case-insensitive, regardless of collation. For example, the following object IDs are considered identical: 54321abcdef, 54321ABCDEF, 54321AbCdEf. Internally, Analysis Services treats the characters in the string as if all are uppercase, and then performs a simple byte comparison that is independent of language.</p> <p>Note that only the 26 characters are affected. If the language is West European, but uses Scandinavian characters, the additional character will not be upper-cased.</p> |
| Cyrillic, Greek, Coptic, Armenian | <p>Object identifiers in non-Latin bicameral script, such as Cyrillic, are always case-sensitive. For example, И́змерение and измерение are considered two distinct values, even though the only difference is the case of the first letter.</p> |

Implications of case-sensitivity for object identifiers

Only object identifiers, and not object names, are subject to the casing behaviors described in the table. If you see a change in how your solution works (a before and after comparison -- after installing SQL Server 2012 SP2 or later), it will most likely be a processing issue. Queries are not impacted by object identifiers. For both query languages (DAX and MDX), the formula engine uses the object name (not the identifier).

NOTE

Code changes related to case-sensitivity have been a breaking change for some applications. See [Breaking Changes to Analysis Services Features in SQL Server 2016](#) for more information.

Locale testing using Excel, SQL Server Profiler and SQL Server Management Studio

When testing translations, the connection must specify the LCID of the translation.

You can do this by hand editing the .odc file to include the locale identifier connection string property. Try this out with the Adventure Works sample multidimensional database.

- Search for existing .odc files. When you find the one for Adventure Works multidimensional, right-click the file to open it in Notepad.
- Add `Locale Identifier=1036` to the connection string. Save and close the file.
- Open Excel | **Data | Existing Connections**. Filter the list to just connections files on this computer. Find the connection for Adventure Works (look at the name carefully; you might have more than one). Open the connection.

You should see the French translations from the Adventure Works sample database.

| Montant Étendu | Column Labels | | | | | | | |
|--------------------|---------------|---------------------|------------------------|------------------------|------------------------|--------------------|-------------------------|--|
| Row Labels | | CY 2010 | CY 2011 | CY 2012 | CY 2013 | CY 2014 | Grand Total | |
| Accessoire | | \$1,695.67 | \$46,448.30 | \$149,738.89 | \$1,050,491.71 | \$30,371.35 | \$1,278,745.91 | |
| Vélo | | \$496,652.84 | \$23,598,927.04 | \$28,470,924.71 | \$42,548,662.26 | | \$95,115,166.84 | |
| Vêtements | | \$2,875.15 | \$137,791.42 | \$767,121.56 | \$1,215,466.43 | \$15,323.37 | \$2,138,577.94 | |
| Composant | | \$31,525.96 | \$1,643,653.12 | \$4,752,196.11 | \$5,376,916.21 | | \$11,804,291.40 | |
| Grand Total | | \$532,749.62 | \$25,426,819.87 | \$34,139,981.27 | \$50,191,536.61 | \$45,694.72 | \$110,336,782.09 | |

As a follow up, you can use SQL Server Profiler to confirm the locale. Click a `Session Initialize` event and then look at the property list in the text area below to find `<localeidentifier>1036</localeidentifier>`.

In Management Studio, you can specify Locale Identifier on a server connection.

- In Object Explorer | **Connect | Analysis Services | Options**, click the **Additional Connection Parameters** tab.
- Enter `Local Identifier=1036` and then click **Connect**.
- Execute an MDX query against the Adventure Works database. The query results should be the French translations.

select non empty [Date].[Calendar].[Calendar Year] on 0,
[Product].[Product Categories].members on 1
FROM [Adventure Works]

| | CY 2010 | CY 2011 | CY 2012 | CY 2013 |
|------------------------------|--------------|-----------------|-----------------|-----------------|
| Tous les Produits | \$489,328.58 | \$18,192,802.71 | \$28,193,631.53 | \$33,574,834.16 |
| Accessoire | \$1,695.67 | \$45,596.79 | \$145,107.49 | \$378,897.98 |
| Porte-vélo | (null) | (null) | \$14,905.27 | \$182,830.88 |
| Range-vélo | (null) | (null) | \$14,905.27 | \$182,830.88 |
| Range-vélo pour tous modèles | (null) | (null) | (null) | (null) |
| Bidon et porte-bidon | (null) | (null) | \$645.77 | \$6,830.84 |
| Porte-bidon de VTT | (null) | (null) | (null) | (null) |
| Porte-bidon de vélo de route | (null) | (null) | (null) | (null) |

Writing MDX queries in a solution containing Translations

Translations provide display information for the names of Analysis Services objects, but the identifiers for the same objects are not translated. Whenever possible, use the identifiers and keys for Analysis Services objects instead of the translated captions and names. For example, use member keys instead of member names for Multidimensional Expressions (MDX) statements and scripts to ensure portability across multiple languages.

NOTE

Recall that tabular object names are always case-insensitive, regardless of collation. Multidimensional object names, on the other hand, follow the case sensitivity of the collation. Since only multidimensional object names are case-sensitive make sure that all MDX queries referencing multidimensional objects are cased correctly.

Writing MDX queries containing Date and Time Values

The following suggestions to make your date and time-based MDX queries more portable across different languages:

1. Use numeric parts for comparisons and operations

When you perform month and day-of-week comparisons and operations, use the numeric date and time parts instead of the string equivalents (for example, use MonthNumberofYear instead of MonthName). Numeric values are least affected by differences in language translations.

2. Use string equivalents in a result set

When building result sets seen by end-users, consider using the string (such as MonthName) so that your multi-lingual audience can benefit from the translations you've provided.

3. Use ISO date formats for universal date and time information

One [Analysis Services expert](#) has this recommendation: "I always use the ISO date format yyyy-mm-dd for any date strings that I pass in to queries in SQL or MDX because it's unambiguous and will work regardless of the client or server's regional settings. I would agree that the server should defer to its regional settings when parsing an ambiguous date format, but I also think that if you've got an option that is not open to interpretation that you are better choosing that anyway".

4. Use the Format function to enforce a specific format, regardless of regional language settings

The following MDX query, borrowed from a forum post, illustrates how to use Format to return dates in a specific format, irrespective of the underlying regional settings.

```
WITH MEMBER [LinkTimeAdd11Date_Manual] as Format(dateadd("d",15,"2014-12-11"), "mm/dd/yyyy")
member [LinkTimeAdd15Date_Manual] as Format(dateadd("d",11,"2014-12-13"), "mm/dd/yyyy")
SELECT
{ [LinkTimeAdd11Date_Manual]
,[LinkTimeAdd15Date_Manual]
}
ON COLUMNS
FROM [Adventure Works]
```

Adventure Works Internet Sales tutorial (1400)

10/22/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

This tutorial provides lessons on how to create and deploy a tabular model at the **1400 compatibility level**. If you're new to Analysis Services and tabular modeling, completing this tutorial is the quickest way to learn how to create and deploy a basic tabular model by using Visual Studio. Once you have the prerequisites in-place, it should take two to three hours to complete.

What you learn

- How to create a new tabular model project at the **1400 compatibility level** in Visual Studio.
- How to import data from a relational database into a tabular model project workspace database.
- How to create and manage relationships between tables in the model.
- How to create calculated columns, measures, and Key Performance Indicators that help users analyze critical business metrics.
- How to create and manage perspectives and hierarchies that help users more easily browse model data by providing business and application-specific viewpoints.
- How to create partitions that divide table data into smaller logical parts that can be processed independent from other partitions.
- How to secure model objects and data by creating roles with user members.
- How to deploy a tabular model to an **Azure Analysis Services** server or **SQL Server Analysis Services** by using Visual Studio.

Prerequisites

To complete this tutorial, you need:

- An Azure Analysis Services server or a SQL Server 2017 Analysis Services server in Tabular mode. Sign up for a free [Azure Analysis Services trial](#) and [create a server](#) or download a free [SQL Server 2017 Developer Edition](#).
- An [Azure SQL Data Warehouse](#) with the **sample AdventureWorksDW database**, or an on-premises SQL Server Data Warehouse with an [AdventureWorksDW sample database](#). When installing an AdventureWorksDW database to an on-premises SQL Server Data Warehouse, use the sample database version that corresponds with your server version.

Important: If you install the sample database to an on-premises SQL Server Data Warehouse, and deploy your model to an Azure Analysis Services server, an [On-premises data gateway](#) is required.

- The latest version of [Visual Studio](#), and the latest [Microsoft Analysis Services Projects](#) (VSIX) package.
- The latest version of [SQL Server Management Studio \(SSMS\)](#).
- A client application such as [Power BI Desktop](#) or Excel.

Scenario

This tutorial is based on Adventure Works Cycles, a fictitious company. Adventure Works is a large, multinational manufacturing company that produces and distributes bicycles, parts, and accessories for commercial markets in North America, Europe, and Asia. The company employs 500 workers. Additionally, Adventure Works employs several regional sales teams throughout its market base. Your project is to create a tabular model for sales and marketing users to analyze Internet sales data in the AdventureWorksDW database.

To complete the tutorial, you must complete various lessons. In each lesson, there are tasks. Completing each task in order is necessary for completing the lesson. While in a particular lesson there may be several tasks that accomplish a similar outcome, but how you complete each task is slightly different. This method shows there is often more than one way to complete a task, and to challenge you by using skills you've learned in previous lessons and tasks.

The purpose of the lessons is to guide you through authoring a basic tabular model by using many of the features included in Visual Studio with Analysis Services projects. Because each lesson builds upon the previous lesson, you should complete the lessons in order.

This tutorial does not provide lessons about managing a server in Azure portal, managing a server or database by using SSMS, or using a client application to browse model data.

Lessons

This tutorial includes the following lessons:

| LESSON | ESTIMATED TIME TO COMPLETE |
|---|----------------------------|
| 1 - Create a new tabular model project | 10 minutes |
| 2 - Get data | 10 minutes |
| 3 - Mark as Date Table | 3 minutes |
| 4 - Create relationships | 10 minutes |
| 5 - Create calculated columns | 15 minutes |
| 6 - Create measures | 30 minutes |
| 7 - Create Key Performance Indicators (KPI) | 15 minutes |
| 8 - Create perspectives | 5 minutes |
| 9 - Create hierarchies | 20 minutes |
| 10 - Create partitions | 15 minutes |
| 11 - Create roles | 15 minutes |
| 12 - Analyze in Excel | 5 minutes |
| 13 - Deploy | 5 minutes |

Supplemental lessons

These lessons are not required to complete the tutorial, but can be helpful in better understanding advanced tabular model authoring features.

| LESSON | ESTIMATED TIME TO COMPLETE |
|------------------------------------|----------------------------|
| Detail Rows | 10 minutes |
| Dynamic security | 30 minutes |
| Ragged hierarchies | 20 minutes |

Next steps

To get started, see [Lesson 1: Create a new tabular model project](#).

Create a tabular model project

10/22/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you use Visual Studio with Microsoft Analysis Services Projects VSIX to create a new tabular model project at the 1400 compatibility level. Once your new project is created, you can begin adding data and authoring your model. This lesson also gives you a brief introduction to the tabular model authoring environment in Visual Studio.

Estimated time to complete this lesson: **10 minutes**

Prerequisites

This article is the first lesson in a tabular model authoring tutorial. To complete this lesson, there are several prerequisites you need to have in-place. To learn more, see [Analysis Services - Adventure Works tutorial](#).

Create a new tabular model project

To create a new tabular model project

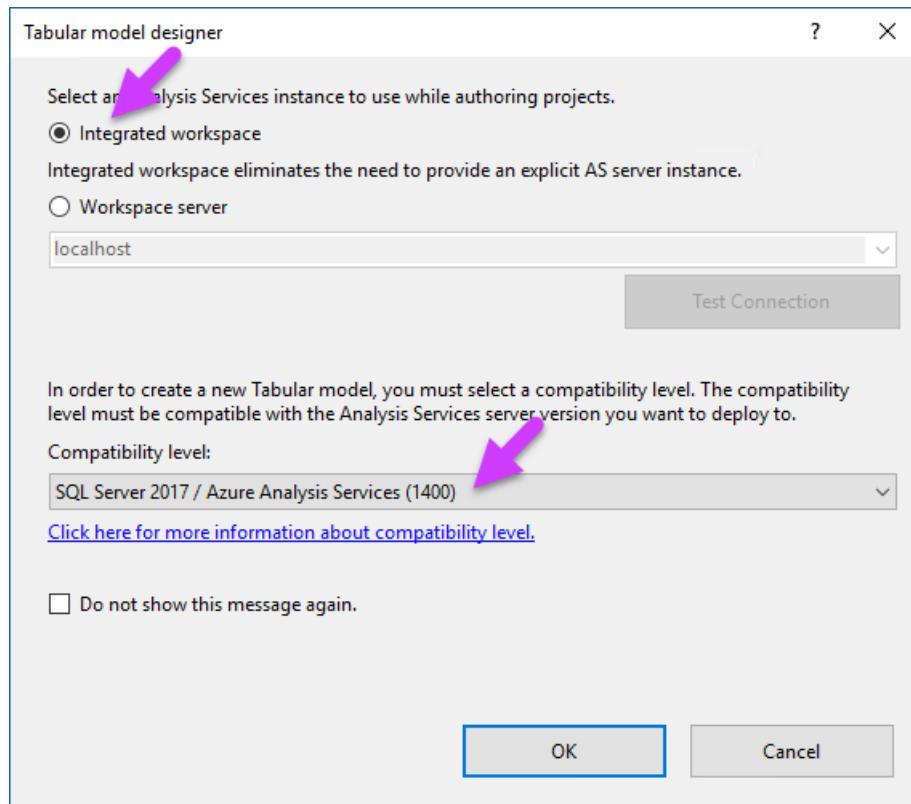

1. In Visual Studio, on the **File** menu, click **New > Project**.
2. In the **New Project** dialog box, expand **Installed > Business Intelligence > Analysis Services**, and then click **Analysis Services Tabular Project**.
3. In **Name**, type **AW Internet Sales**, and then specify a location for the project files.

By default, **Solution Name** is the same as the project name; however, you can type a different solution name.

4. Click **OK**.
5. In the **Tabular model designer** dialog box, select **Integrated workspace**.

The workspace hosts a tabular model database with the same name as the project during model authoring. Integrated workspace means Visual Studio uses a built-in instance, eliminating the need to install a separate Analysis Services server instance just for model authoring.

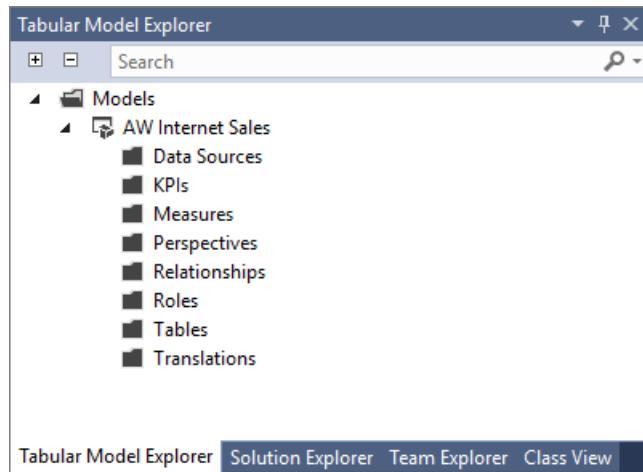

6. In **Compatibility level**, select **SQL Server 2017 / Azure Analysis Services (1400)**.

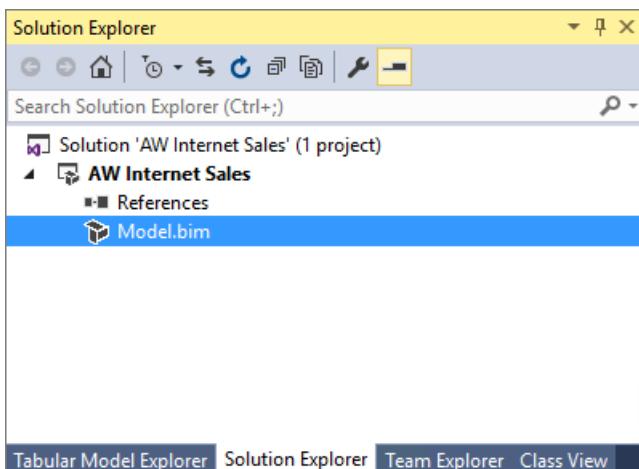

Understanding the tabular model authoring environment

Now that you've created a new tabular model project, let's take a moment to explore the tabular model authoring environment in Visual Studio.

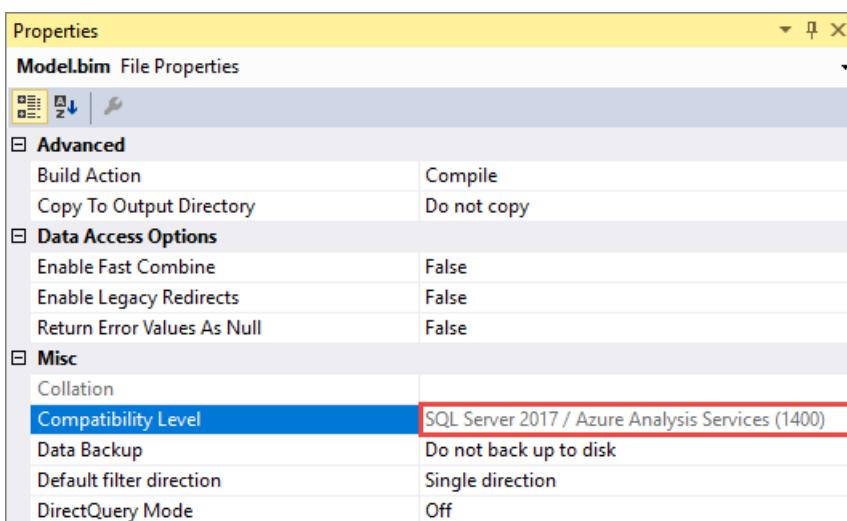

After your project is created, it opens in Visual Studio. On the right side, in **Tabular Model Explorer**, you see a tree view of the objects in your model. Since you haven't yet imported data, the folders are empty. You can right-click an object folder to perform actions, similar to the menu bar. As you step through this tutorial, you use the Tabular Model Explorer to navigate different objects in your model project.

Click the **Solution Explorer** tab. Here, you see your **Model.bim** file. If you don't see the designer window to the left (the empty window with the Model.bim tab), in **Solution Explorer**, under **AW Internet Sales Project**, double-click the **Model.bim** file. The Model.bim file contains the metadata for your model project.

Click **Model.bim**. In the **Properties** window, you see the model properties, most important of which is the **DirectQuery Mode** property. This property specifies if the model is deployed in In-Memory mode (Off) or DirectQuery mode (On). For this tutorial, you author and deploy your model in In-Memory mode.

When you create a model project, certain model properties are set automatically according to the Data Modeling settings that can be specified in the **Tools** menu > **Options** dialog box. Data Backup, Workspace Retention, and Workspace Server properties specify how and where the workspace database (your model authoring database) is backed up, retained in-memory, and built. You can change these settings later if necessary, but for now, leave these properties as they are.

In **Solution Explorer**, right-click **AW Internet Sales** (project), and then click **Properties**. The **AW Internet Sales Property Pages** dialog box appears. You set some of these properties later when you deploy your model.

When you installed the Analysis Services projects extension, several new menu items were added to the Visual Studio environment. Click the **Model** menu. From here, you can import data, refresh workspace data, browse your model in Excel, create perspectives and roles, select the model view, and set calculation options. Click the **Table** menu. From here, you can create and manage relationships, specify date table settings, create partitions, and edit table properties. If you click the **Column** menu, you can add and delete columns in a table, freeze columns, and specify sort order. The extension also adds some buttons to the bar. Most useful is the AutoSum feature to create a standard aggregation measure for a selected column. Other toolbar buttons provide quick access to frequently used features and commands.

Explore some of the dialogs and locations for various features specific to authoring tabular models. While some items are not yet active, you can get a good idea of the tabular model authoring environment.

What's next?

[Lesson 2: Get data.](#)

Get data

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you use **Get Data** to connect to the AdventureWorksDW sample database, select data, preview and filter, and then import into your model workspace.

Under the hood, Get Data is Power Query, which provides a vast array of tools for connecting to and reshaping data for modeling and analysis. To learn more, see [Power Query Documentation](#).

NOTE

Tasks and images in this tutorial show connecting to an AdventureWorksDW2014 database on an on-premises server. In some cases, an AdventureWorksDW database on Azure SQL Data Warehouse may show different objects; however, they are fundamentally the same.

Estimated time to complete this lesson: **10 minutes**

Prerequisites

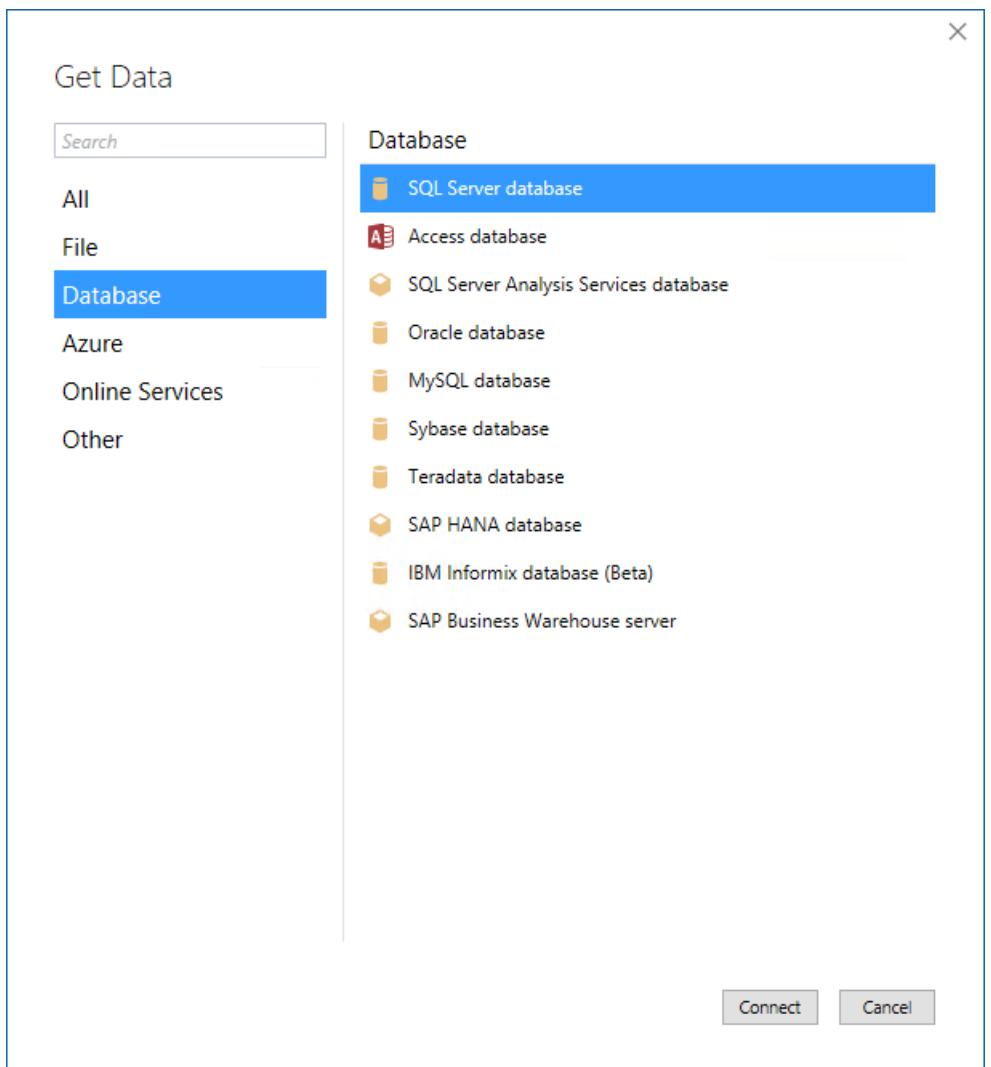

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 1: Create a new tabular model project](#).

Create a connection

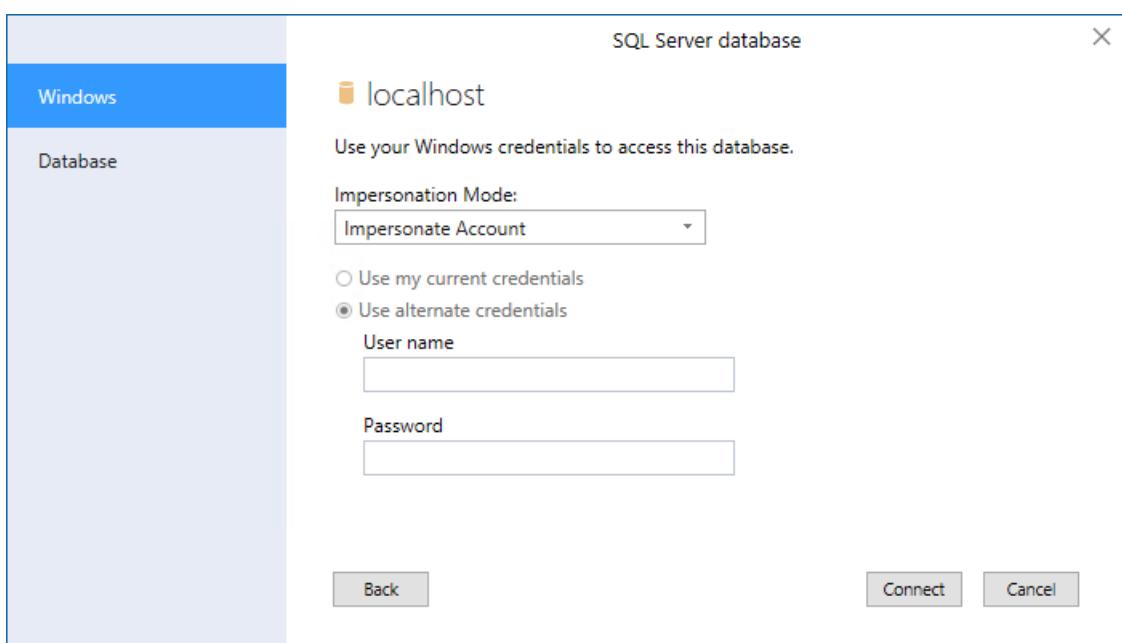

To create a connection to the AdventureWorksDW database

1. In **Tabular Model Explorer**, right-click **Data Sources** > **Import from Data Source**.

This launches **Get Data**, which guides you through connecting to a data source. If you don't see Tabular Model Explorer, in **Solution Explorer**, double-click **Model.bim** to open the model in the designer.

2. In Get Data, click **Database** > **SQL Server Database** > **Connect**.
3. In the **SQL Server Database** dialog, in **Server**, type the name of the server where you installed the AdventureWorksDW database, and then click **Connect**.
4. When prompted to enter credentials, you need to specify the credentials Analysis Services uses to connect to the data source when importing and processing data. In **Impersonation Mode**, select **Impersonate Account**, then enter credentials, and then click **Connect**. It's recommended you use an account where the password doesn't expire.

NOTE

Using a Windows user account and password provides the most secure method of connecting to a data source.

5. In Navigator, select the **AdventureWorksDW** database, and then click **OK**. This creates the connection to the database.
6. In Navigator, select the check box for the following tables: **DimCustomer**, **DimDate**, **DimGeography**, **DimProduct**, **DimProductCategory**, **DimProductSubcategory**, and **FactInternetSales**. After selecting the tables, click **Edit**.

The screenshot shows the Microsoft Data Explorer 'Navigator' window. On the left, a list of tables is displayed with checkboxes next to them. Several checkboxes are checked, including DimGeography, DimProduct, DimProductCategory, DimProductSubcategory, and FactInternetSales. FactInternetSales is highlighted with a yellow background. On the right, a preview of the FactInternetSales table is shown in a grid format. The columns are ProductKey, OrderDateKey, DueDateKey, ShipDateKey, CustomerKey, and Pro. The data is truncated due to size limits. At the bottom of the window, there are buttons for Load, Edit (which is highlighted with a red box), and Cancel.

| ProductKey | OrderDateKey | DueDateKey | ShipDateKey | CustomerKey | Pro |
|------------|--------------|------------|-------------|-------------|-----|
| 310 | 20101229 | 20110110 | 20110105 | 21768 | |
| 346 | 20101229 | 20110110 | 20110105 | 28389 | |
| 346 | 20101229 | 20110110 | 20110105 | 25863 | |
| 336 | 20101229 | 20110110 | 20110105 | 14501 | |
| 346 | 20101229 | 20110110 | 20110105 | 11003 | |
| 311 | 20101230 | 20110111 | 20110106 | 27645 | |
| 310 | 20101230 | 20110111 | 20110106 | 16624 | |
| 351 | 20101230 | 20110111 | 20110106 | 11005 | |
| 344 | 20101230 | 20110111 | 20110106 | 11011 | |
| 312 | 20101231 | 20110112 | 20110107 | 27621 | |
| 312 | 20101231 | 20110112 | 20110107 | 27616 | |
| 330 | 20101231 | 20110112 | 20110107 | 20042 | |
| 313 | 20101231 | 20110112 | 20110107 | 16351 | |
| 314 | 20101231 | 20110112 | 20110107 | 16517 | |

After you click **Edit**, Query Editor opens. In the next section, you select only the data you want to import.

Filter the table data

Tables in the AdventureWorksDW sample database have data that isn't necessary to include in your model. When possible, you want to filter out unnecessary data to save in-memory space used by the model. You filter out some of the columns from tables so they're not imported into the workspace database, or the model database after it has been deployed.

To filter the table data before importing

1. In Query Editor, select the **DimCustomer** table. A view of the DimCustomer table at the datasource (your AdventureWorksDW sample database) appears.
2. Multi-select (Ctrl + click) **SpanishEducation**, **FrenchEducation**, **SpanishOccupation**, **FrenchOccupation**, then right-click, and then click **Remove Columns**.

PREVIEW DOWNLOADED AT 2:26 PM

Since the values for these columns are not relevant to Internet sales analysis, there is no need to import these columns. Eliminating unnecessary columns makes your model smaller and more efficient.

TIP

If you make a mistake, you can backup by deleting a step in **APPLIED STEPS**.

Query Settings

| SpanishProductCategoryName |
| FrenchProductCategoryName |

DimProductSubcategory

| COLUMN |
|--------------------------------------|
| SpanishProductSubcategoryName |
| FrenchProductSubcategoryName |

FactInternetSales

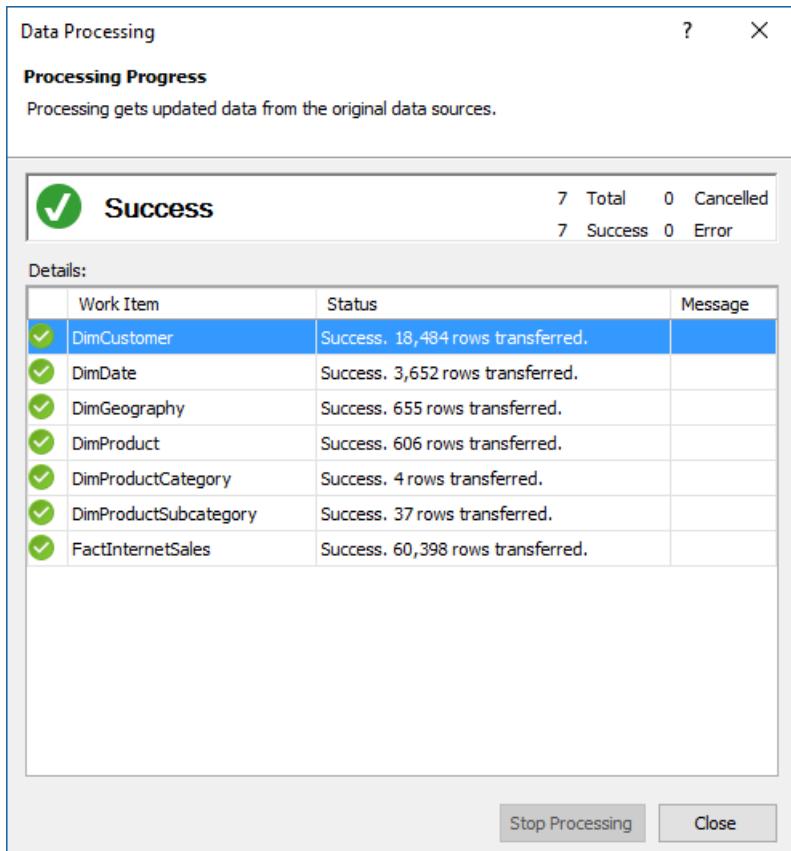

No columns removed.

Import the selected tables and column data

Now that you've previewed and filtered out unnecessary data, you can import the rest of the data you do want. The wizard imports the table data along with any relationships between tables. New tables and columns are created in the model and data that you filtered out is not imported.

To import the selected tables and column data

1. Review your selections. If everything looks okay, click **Import**. The Data Processing dialog shows the status of data being imported from your datasource into your workspace database.

2. Click **Close**.

Save your model project

It's important to frequently save your model project.

To save the model project

- Click **File > Save All**.

What's next?

[Lesson 3: Mark as Date Table.](#)

Mark as Date Table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In Lesson 2: Get data, you imported a dimension table named **DimDate**. While in your model this table is named DimDate, it can also be known as a *Date table*, in that it contains date and time data.

Whenever you use DAX time-intelligence functions, like when you create measures later, you must specify properties which include a *Date table* and a unique identifier *Date column* in that table.

In this lesson, you mark the **DimDate** table as the *Date table* and the **Date** column (in the Date table) as the *Date column* (unique identifier).

Before you mark the date table and date column, it's a good time to do a little housekeeping to make your model easier to understand. Notice in the DimDate table a column named **FullDateAlternateKey**. This column contains one row for every day in each calendar year included in the table. You use this column a lot in measure formulas and in reports. But, FullDateAlternateKey isn't really a good identifier for this column. You rename it to **Date**, making it easier to identify and include in formulas. Whenever possible, it's a good idea to rename objects like tables and columns to make them easier to identify in SSDT and client reporting applications.

Estimated time to complete this lesson: **Three minutes**

Prerequisites

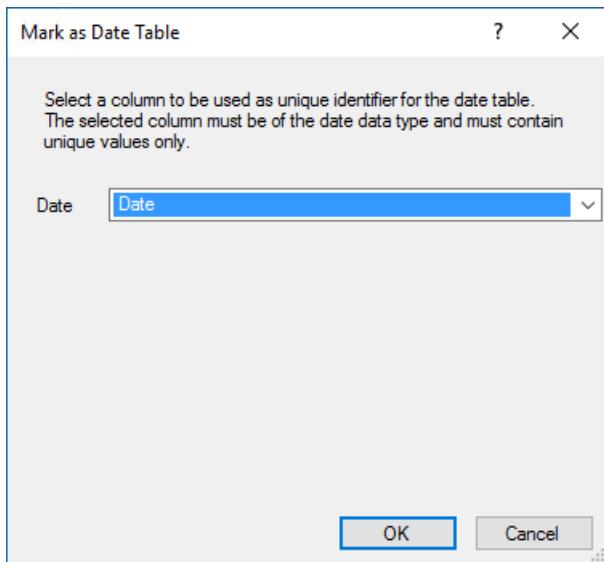

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 2: Get data](#).

To rename the **FullDateAlternateKey** column

1. In the model designer, click the **DimDate** table.
2. Double-click the header for the **FullDateAlternateKey** column, and then rename it to **Date**.

To set **Mark as Date Table**

1. Select the **Date** column, and then in the **Properties** window, under **Data Type**, make sure **Date** is selected.
2. Click the **Table** menu, then click **Date**, and then click **Mark as Date Table**.
3. In the **Mark as Date Table** dialog box, in the **Date** listbox, select the **Date** column as the unique identifier. It's usually selected by default. Click **OK**.

What's next?

[Lesson 4: Create relationships.](#)

Create relationships

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services (starting with 2017) ✓ Azure Analysis Services ✗ Power BI Premium

In this lesson, you verify the relationships that were created automatically when you imported data and add new relationships between different tables. A relationship is a connection between two tables that establishes how the data in those tables should be correlated. For example, the DimProduct table and the DimProductSubcategory table have a relationship based on the fact that each product belongs to a subcategory. To learn more, see [Relationships](#).

Estimated time to complete this lesson: **10 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 3: Mark as Date Table](#).

Review existing relationships and add new relationships

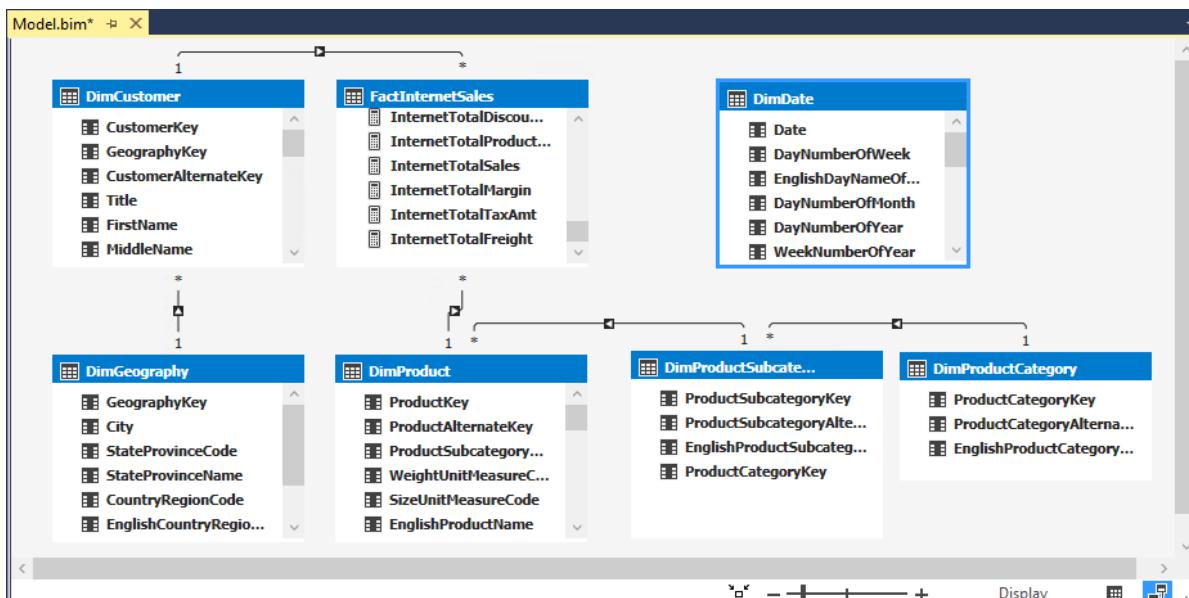

When you imported data by using Get Data, you got seven tables from the AdventureWorksDW database. Generally, when you import data from a relational source, existing relationships are automatically imported together with the data. In order for Get Data to automatically create relationships in the data model, there must be relationships between tables at the data source.

Before you proceed with authoring your model, you should verify those relationships between tables were created properly. For this tutorial, you also add three new relationships.

To review existing relationships

1. Click the **Model** menu > **Model View** > **Diagram View**.

The model designer now appears in Diagram View, a graphical format displaying all the tables you imported with lines between them. The lines between tables indicate the relationships that were automatically created when you imported the data.

NOTE

If you don't see any relationships between tables, it likely means there are no relationships between those tables at the datasource.

Include as many of the tables as possible by using minimap controls in the lower-right corner of the model designer. You can also click and drag tables to different locations, bringing tables closer together, or putting them in a particular order. Moving tables does not affect the relationships between the tables. To view all the columns in a particular table, click and drag on a table edge to expand or make it smaller.

2. Click the solid line between the **DimCustomer** table and the **DimGeography** table. The solid line between these two tables shows this relationship is active, that is, it is used by default when calculating DAX formulas.

Notice the **GeographyKey** column in the **DimCustomer** table and the **GeographyKey** column in the **DimGeography** table now both each appear within a box. These columns are used in the relationship. The relationship's properties now also appear in the **Properties** window.

TIP

You can also use the Manage Relationships dialog box to show the relationships between all tables in a table format. In Tabular Model Explorer, right-click **Relationships** > **Manage Relationships**.

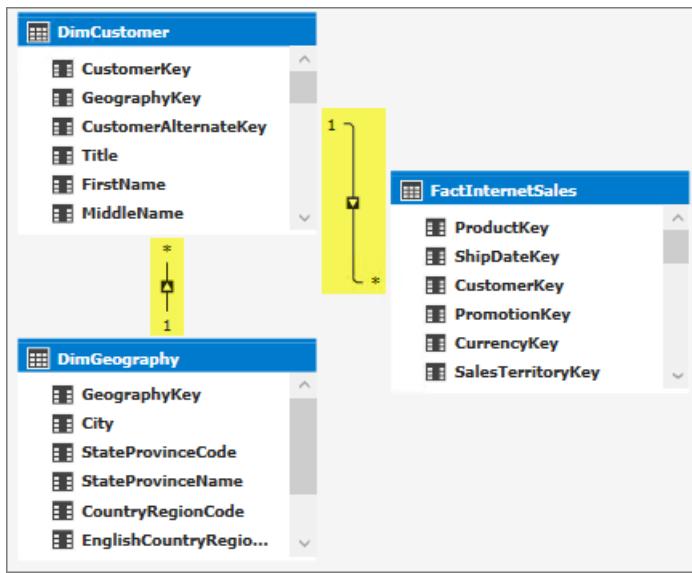

3. Verify the following relationships were created when each of the tables were imported from the AdventureWorksDW database:

| ACTIVE | TABLE | RELATED LOOKUP TABLE |
|--------|---|--|
| Yes | DimCustomer [GeographyKey] | DimGeography [GeographyKey] |
| Yes | DimProduct
[ProductSubcategoryKey] | DimProductSubcategory
[ProductSubcategoryKey] |
| Yes | DimProductSubcategory
[ProductCategoryKey] | DimProductCategory
[ProductCategoryKey] |
| Yes | FactInternetSales [CustomerKey] | DimCustomer [CustomerKey] |
| Yes | FactInternetSales [ProductKey] | DimProduct [ProductKey] |

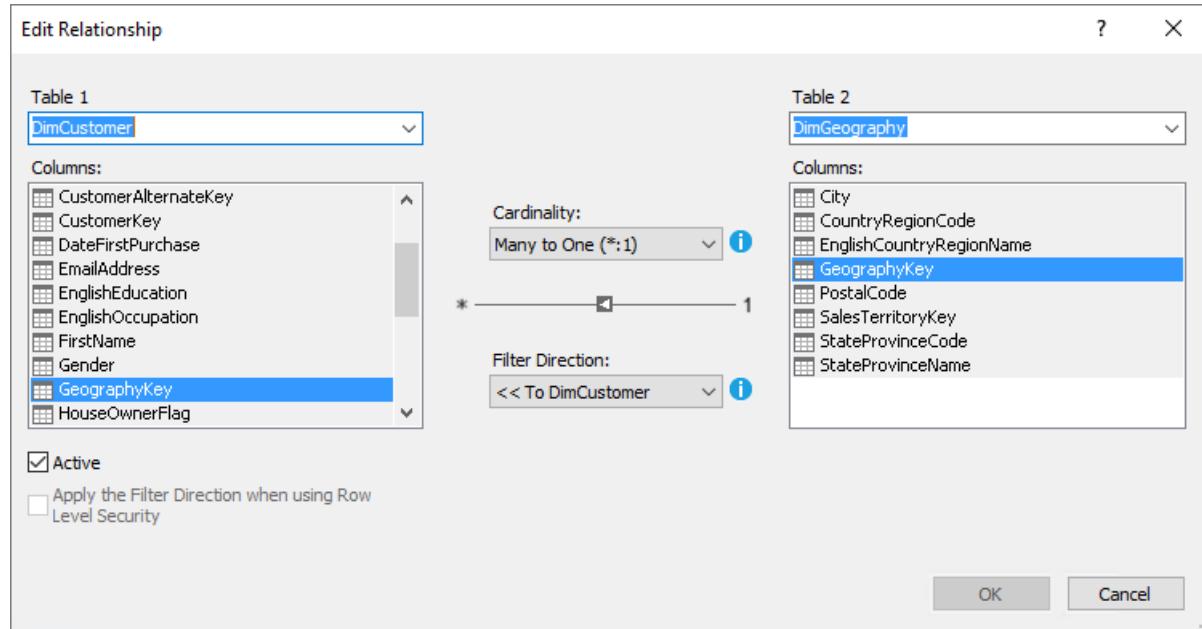

If any of the relationships are missing, verify your model includes the following tables: DimCustomer, DimDate, DimGeography, DimProduct, DimProductCategory, DimProductSubcategory, and FactInternetSales. If tables from the same datasource connection are imported at separate times, any relationships between those tables are not be created and must be created manually. If no relationships appear, it means there are no relationships at the datasource. You can create them manually in the data model.

Take a closer look

In Diagram View, notice an arrow, an asterisk, and a number on the lines that show the relationship between tables.

The arrow shows the filter direction. The asterisk shows this table is the *many* side in the relationship's cardinality, and the one shows this table is the *one* side of the relationship. If you need to edit a relationship; for example, change the relationship's filter direction or cardinality, double-click the relationship line to open the Edit Relationship dialog.

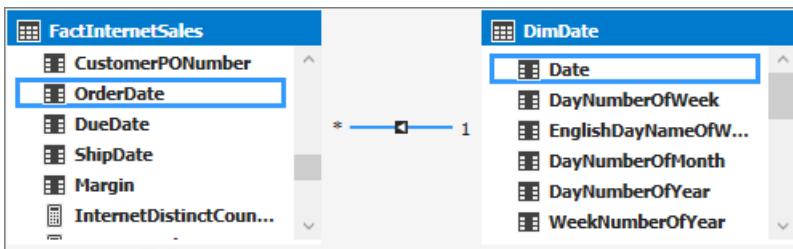

These features are meant for advanced data modeling and are outside the scope of this tutorial. To learn more, see [Bi-directional cross filters for tabular models in Analysis Services](#).

In some cases, you may need to create additional relationships between tables in your model to support certain business logic. For this tutorial, you need to create three additional relationships between the FactInternetSales table and the DimDate table.

To add new relationships between tables

1. In the model designer, in the **FactInternetSales** table, click, and hold on the **OrderDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

A solid line appears showing you have created an active relationship between the **OrderDate** column in the **Internet Sales** table, and the **Date** column in the **Date** table.

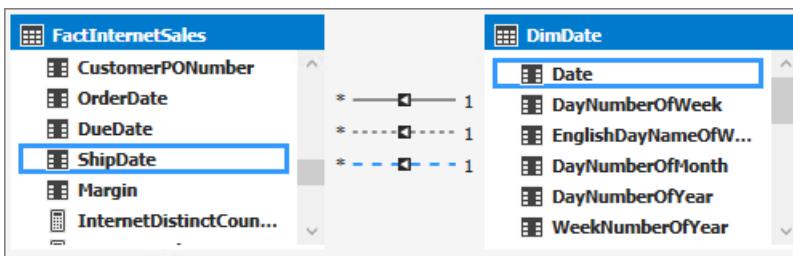

NOTE

When creating relationships, the cardinality and filter direction between the primary table and the related lookup table is automatically selected.

2. In the **FactInternetSales** table, click and hold on the **DueDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

A dotted line appears showing you have created an inactive relationship between the **DueDate** column in the **FactInternetSales** table, and the **Date** column in the **DimDate** table. You can have multiple relationships between tables, but only one relationship can be active at a time. Inactive relationships can be made active to perform special aggregations in custom DAX expressions.

3. Finally, create one more relationship. In the **FactInternetSales** table, click and hold on the **ShipDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

What's next?

[Lesson 5: Create calculated columns.](#)

Create calculated columns

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create data in your model by adding calculated columns. You can create calculated columns (as custom columns) when using Get Data, by using the Query Editor, or later in the model designer like you do here. To learn more, see [Calculated columns](#).

You create five new calculated columns in three different tables. The steps are slightly different for each task showing there are several ways to create columns, rename them, and place them in various locations in a table.

This lesson is also where you first use Data Analysis Expressions (DAX). DAX is a special language for creating highly customizable formula expressions for tabular models. In this tutorial, you use DAX to create calculated columns, measures, and role filters. To learn more, see [DAX in tabular models](#).

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 4: Create relationships](#).

Create calculated columns

Create a MonthCalendar calculated column in the DimDate table

1. Click the **Model** menu > **Model View** > **Data View**.

Calculated columns can only be created by using the model designer in Data View.

2. In the model designer, click the **DimDate** table (tab).
3. Right-click the **CalendarQuarter** column header, and then click **Insert Column**.

A new column named **Calculated Column 1** is inserted to the left of the **Calendar Quarter** column.

4. In the formula bar above the table, type the following DAX formula: Auto-Complete helps you type the fully qualified names of columns and tables, and lists the functions that are available.

```
=RIGHT(" " & FORMAT([MonthNumberOfYear],"#0"), 2) & " - " & [EnglishMonthName]
```

Values are then populated for all the rows in the calculated column. If you scroll down through the table, you see rows can have different values for this column, based on the data in each row.

5. Rename this column to **MonthCalendar**.

| Name | MonthNumberOfYear | MonthName | CalendarQuarter | CalendarYear | CalendarSemester | FiscalQua |
|------|-------------------|------------|-----------------|--------------|------------------|-----------|
| 29 | | 7 - July | 3 | 2010 | 2 | |
| 30 | | 7 - July | 3 | 2010 | 2 | |
| 31 | | 7 - July | 3 | 2010 | 2 | |
| 32 | | 8 - August | 3 | 2010 | 2 | |
| 33 | | 8 - August | 3 | 2010 | 2 | |
| 34 | | 8 - August | 3 | 2010 | 2 | |

The MonthCalendar calculated column provides a sortable name for Month.

Create a DayOfWeek calculated column in the DimDate table

- With the **DimDate** table still active, click the **Column** menu, and then click **Add Column**.
- In the formula bar, type the following formula:

```
=RIGHT(" " & FORMAT([DayNumberOfWeek],"#0"), 2) & " - " & [EnglishDayNameOfWeek]
```

When you've finished building the formula, press ENTER. The new column is added to the far right of the table.

- Rename the column to **DayOfWeek**.
- Click the column heading, and then drag the column between the **EnglishDayNameOfWeek** column and the **DayNumberOfMonth** column.

TIP

Moving columns in your table makes it easier to navigate.

The DayOfWeek calculated column provides a sortable name for the day of week.

Create a ProductSubcategoryName calculated column in the DimProduct table

- In the **DimProduct** table, scroll to the far right of the table. Notice the right-most column is named **Add Column**, click the column heading.
- In the formula bar, type the following formula:

```
=RELATED('DimProductSubcategory'[EnglishProductSubcategoryName])
```

- Rename the column to **ProductSubcategoryName**.

The ProductSubcategoryName calculated column is used to create a hierarchy in the DimProduct table, which includes data from the EnglishProductSubcategoryName column in the DimProductSubcategory table.

Hierarchies cannot span more than one table. You create hierarchies later in Lesson 9.

Create a ProductCategoryName calculated column in the DimProduct table

- With the **DimProduct** table still active, click the **Column** menu, and then click **Add Column**.
- In the formula bar, type the following formula:

```
=RELATED('DimProductCategory'[EnglishProductCategoryName])
```

- Rename the column to **ProductCategoryName**.

The ProductCategoryName calculated column is used to create a hierarchy in the DimProduct table, which

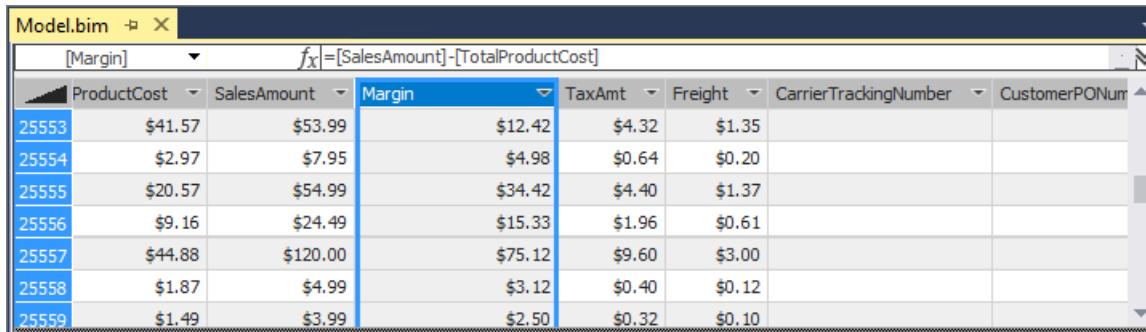

includes data from the EnglishProductName column in the DimProductCategory table. Hierarchies cannot span more than one table.

Create a Margin calculated column in the FactInternetSales table

1. In the model designer, select the **FactInternetSales** table.
2. Create a new calculated column between the **SalesAmount** column and the **TaxAmt** column.
3. In the formula bar, type the following formula:

```
=[SalesAmount]-[TotalProductCost]
```

4. Rename the column to **Margin**.

The screenshot shows the Microsoft Power BI Model.bim table editor. A new column named 'Margin' has been added between the 'SalesAmount' and 'TaxAmt' columns. The formula for the Margin column is displayed in the formula bar: `f_x=[SalesAmount]-[TotalProductCost]`. The table contains several rows of sales data, including ProductCost, SalesAmount, Margin, TaxAmt, Freight, CarrierTrackingNumber, and CustomerPONum.

| | ProductCost | SalesAmount | Margin | TaxAmt | Freight | CarrierTrackingNumber | CustomerPONum |
|-------|-------------|-------------|---------|--------|---------|-----------------------|---------------|
| 25553 | \$41.57 | \$53.99 | \$12.42 | \$4.32 | \$1.35 | | |
| 25554 | \$2.97 | \$7.95 | \$4.98 | \$0.64 | \$0.20 | | |
| 25555 | \$20.57 | \$54.99 | \$34.42 | \$4.40 | \$1.37 | | |
| 25556 | \$9.16 | \$24.49 | \$15.33 | \$1.96 | \$0.61 | | |
| 25557 | \$44.88 | \$120.00 | \$75.12 | \$9.60 | \$3.00 | | |
| 25558 | \$1.87 | \$4.99 | \$3.12 | \$0.40 | \$0.12 | | |
| 25559 | \$1.49 | \$3.99 | \$2.50 | \$0.32 | \$0.10 | | |

The Margin calculated column is used to analyze profit margins for each sale.

What's next?

[Lesson 6: Create measures.](#)

Create measures

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create measures to be included in your model. Similar to the calculated columns you created, a measure is a calculation created by using a DAX formula. However, unlike calculated columns, measures are evaluated based on a user selected *filter*. For example, a particular column or slicer added to the Row Labels field in a PivotTable. A value for each cell in the filter is then calculated by the applied measure. Measures are powerful, flexible calculations that you want to include in almost all tabular models to perform dynamic calculations on numerical data. To learn more, see [Measures](#).

To create measures, you use the *Measure Grid*. By default, each table has an empty measure grid; however, you typically do not create measures for every table. The measure grid appears below a table in the model designer when in Data View. To hide or show the measure grid for a table, click the **Table** menu, and then click **Show Measure Grid**.

You can create a measure by clicking an empty cell in the measure grid, and then typing a DAX formula in the formula bar. When you click ENTER to complete the formula, the measure then appears in the cell. You can also create measures using a standard aggregation function by clicking a column, and then clicking the AutoSum button (Σ) on the toolbar. Measures created using the AutoSum feature appear in the measure grid cell directly beneath the column, but can be moved.

In this lesson, you create measures by both entering a DAX formula in the formula bar, and by using the AutoSum feature.

Estimated time to complete this lesson: **30 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 5: Create calculated columns](#).

Create measures

To create a DaysCurrentQuarterToDate measure in the DimDate table

1. In the model designer, click the **DimDate** table.
2. In the measure grid, click the top-left empty cell.
3. In the formula bar, type the following formula:

```
DaysCurrentQuarterToDate:=COUNTRROWS( DATESQTD( 'DimDate'[Date]))
```

Notice the top-left cell now contains a measure name, **DaysCurrentQuarterToDate**, followed by the result, **92**. The result is not relevant at this point because no user filter has been applied.

| | [Date] | f(x) | DaysCurrentQuarterToDate:=COUNTROWS(DATESQTD('DimDate'[Date])) | | |
|------------------------------|----------------------|--------|--|--------------|------------------|
| | Date | Day... | EnglishDayNameOfWeek | DayOfWeek | DayNumberOfMonth |
| 1 | 7/1/2010 12:00:00 AM | 5 | Thursday | 5 - Thursday | |
| 2 | 7/2/2010 12:00:00 AM | 6 | Friday | 6 - Friday | |
| 3 | 7/3/2010 12:00:00 AM | 7 | Saturday | 7 - Saturday | |
| 4 | 7/4/2010 12:00:00 AM | 1 | Sunday | 1 - Sunday | |
| 5 | 7/5/2010 12:00:00 AM | 2 | Monday | 2 - Monday | |
| 6 | 7/6/2010 12:00:00 AM | 3 | Tuesday | 3 - Tuesday | |
| DaysCurrentQuarterToDate: 92 | | | | | |

Unlike calculated columns, with measure formulas you can type the measure name, followed by a colon, followed by the formula expression.

To create a DaysInCurrentQuarter measure in the DimDate table

- With the **DimDate** table still active in the model designer, in the measure grid, click the empty cell below the measure you created.
- In the formula bar, type the following formula:

```
DaysInCurrentQuarter:=COUNTROWS( DATESBETWEEN( 'DimDate'[Date], STARTOFQUARTER(LASTDATE('DimDate'[Date])), ENDOFQUARTER('DimDate'[Date])))
```

When creating a comparison ratio between one incomplete period and the previous period. The formula must calculate the proportion of the period that has elapsed and compare it to the same proportion in the previous period. In this case, [DaysCurrentQuarterToDate]/[DaysInCurrentQuarter] gives the proportion elapsed in the current period.

To create an InternetDistinctCountSalesOrder measure in the FactInternetSales table

- Click the **FactInternetSales** table.
- Click the **SalesOrderNumber** column heading.
- On the toolbar, click the down-arrow next to the AutoSum (Σ) button, and then select **DistinctCount**.

The AutoSum feature automatically creates a measure for the selected column using the DistinctCount standard aggregation formula.

| | [SalesOrderNumb...] | f(x) | Distinct Count SalesOrderNumber:=DISTINCTCOUNT([SalesOrderNumber]) | | | |
|--|---------------------|-------------------|--|----------------------|----------------|---------------|
| | BusinessKey | SalesTerritoryKey | SalesOrderNumber | SalesOrderLineNumber | RevisionNumber | OrderQuantity |
| 1 | 100 | 4 | SO51900 | 1 | 1 | |
| 2 | 100 | 4 | SO51948 | 1 | 1 | |
| 3 | 100 | 4 | SO52043 | 1 | 1 | |
| 4 | 100 | 4 | SO52045 | 1 | 1 | |
| 5 | 100 | 4 | SO52094 | 1 | 1 | |
| 6 | 100 | 4 | SO52175 | 1 | 1 | |
| Distinct Count SalesOrderNumber: 27659 | | | | | | |

- In the measure grid, click the new measure, and then in the **Properties** window, in **Measure Name**, rename the measure to **InternetDistinctCountSalesOrder**.

To create additional measures in the FactInternetSales table

- By using the AutoSum feature, create and name the following measures:

| COLUMN | MEASURE NAME | AUTOSUM (Σ) | FORMULA |
|----------------------|-------------------------|----------------------|---------------------------------|
| SalesOrderLineNumber | InternetOrderLinesCount | Count | =COUNTA([SalesOrderLineNumber]) |

| COLUMN | MEASURE NAME | AUTOSUM (Σ) | FORMULA |
|------------------|-----------------------------|----------------------|--------------------------|
| OrderQuantity | InternetTotalUnits | Sum | =SUM([OrderQuantity]) |
| DiscountAmount | InternetTotalDiscountAmount | Sum | =SUM([DiscountAmount]) |
| TotalProductCost | InternetTotalProductCost | Sum | =SUM([TotalProductCost]) |
| SalesAmount | InternetTotalSales | Sum | =SUM([SalesAmount]) |
| Margin | InternetTotalMargin | Sum | =SUM([Margin]) |
| TaxAmt | InternetTotalTaxAmt | Sum | =SUM([TaxAmt]) |
| Freight | InternetTotalFreight | Sum | =SUM([Freight]) |

2. By clicking an empty cell in the measure grid, and by using the formula bar, create the following custom measures in order:

```
InternetPreviousQuarterMargin:=CALCULATE([InternetTotalMargin],PREVIOUSQUARTER('DimDate'[Date]))
```

```
InternetCurrentQuarterMargin:=TOTALQTD([InternetTotalMargin],'DimDate'[Date])
```

```
InternetPreviousQuarterMarginProportionToQTD:=[InternetPreviousQuarterMargin]*([DaysCurrentQuarterToDate]/[DaysInCurrentQuarter])
```

```
InternetPreviousQuarterSales:=CALCULATE([InternetTotalSales],PREVIOUSQUARTER('DimDate'[Date]))
```

```
InternetCurrentQuarterSales:=TOTALQTD([InternetTotalSales],'DimDate'[Date])
```

```
InternetPreviousQuarterSalesProportionToQTD:=[InternetPreviousQuarterSales]*([DaysCurrentQuarterToDate]/[DaysInCurrentQuarter])
```

Measures created for the FactInternetSales table can be used to analyze critical financial data such as sales, costs, and profit margin for items defined by the user selected filter.

What's next?

[Lesson 7: Create Key Performance Indicators.](#)

Create Key Performance Indicators

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create Key Performance Indicators (KPIs). KPIs are used to gauge performance of a value defined by a *Base* measure, against a *Target* value also defined by a measure, or by an absolute value. In reporting client applications, KPIs can provide business professionals a quick and easy way to understand a summary of business success or to identify trends. To learn more, see [KPIs](#)

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 6: Create measures](#).

Create Key Performance Indicators

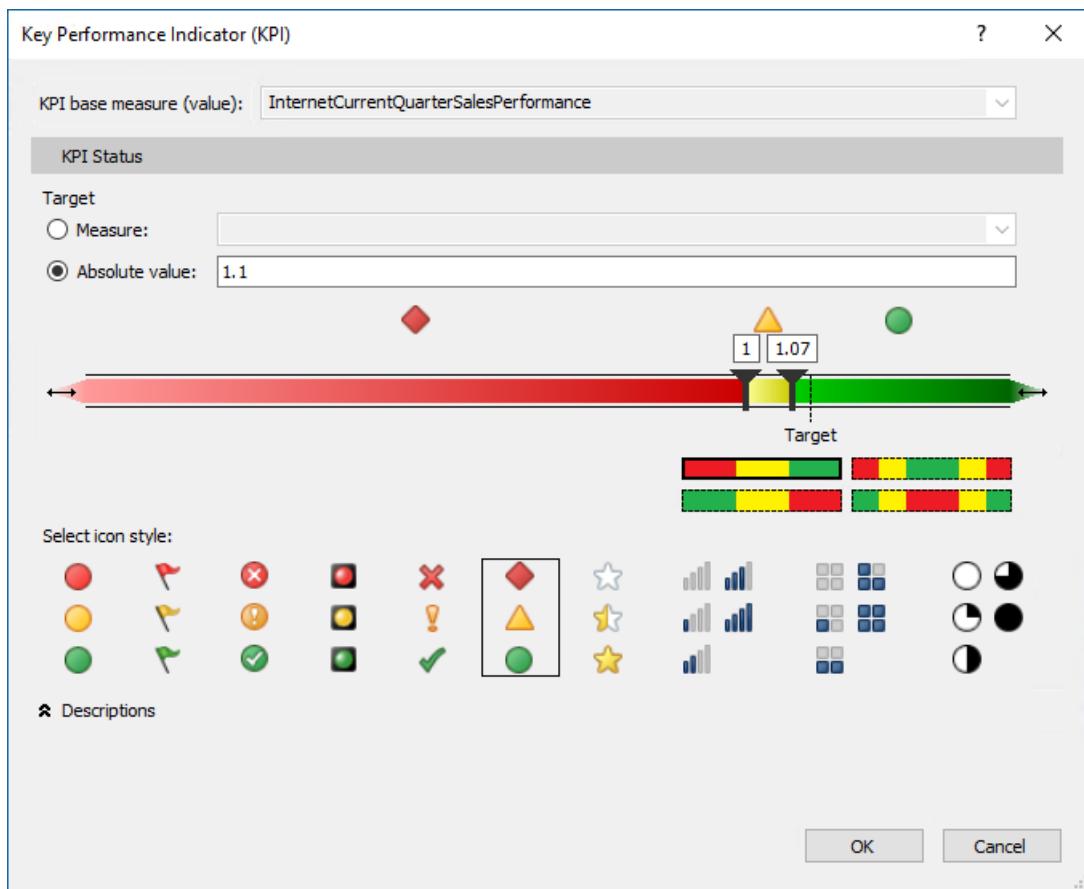

To create an **InternetCurrentQuarterSalesPerformance** KPI

1. In the model designer, click the **FactInternetSales** table.
2. In the measure grid, click an empty cell.
3. In the formula bar, above the table, type the following formula:

```
InternetCurrentQuarterSalesPerformance :=IF([InternetPreviousQuarterSalesProportionToQTD]<>0,  
([InternetCurrentQuarterSales]-  
[InternetPreviousQuarterSalesProportionToQTD])/[InternetPreviousQuarterSalesProportionToQTD],BLANK())
```

This measure serves as the Base measure for the KPI.

4. In the measure grid, right-click **InternetCurrentQuarterSalesPerformance** > **Create KPI**.
5. In the Key Performance Indicator (KPI) dialog box, in **Target** select **Absolute Value**, and then type **1.1**.
6. In the left (low) slider field, type **1**, and then in the right (high) slider field, type **1.07**.
7. In **Select Icon Style**, select the diamond (red), triangle (yellow), circle (green) icon type.

TIP

Notice the expandable **Descriptions** label below the available icon styles. Use descriptions for the various KPI elements to make them more identifiable in client applications.

- Click **OK** to complete the KPI.

In the measure grid, notice the icon next to the **InternetCurrentQuarterSalesPerformance** measure. This icon indicates that this measure serves as a Base value for a KPI.

To create an InternetCurrentQuarterMarginPerformance KPI

- In the measure grid for the **FactInternetSales** table, click an empty cell.
- In the formula bar, above the table, type the following formula:

```
InternetCurrentQuarterMarginPerformance :=IF([InternetPreviousQuarterMarginProportionToQTD]<>0,
([InternetCurrentQuarterMargin]-
[InternetPreviousQuarterMarginProportionToQTD])/[InternetPreviousQuarterMarginProportionToQTD],BLANK())
```

- Right-click **InternetCurrentQuarterMarginPerformance** > **Create KPI**.
- In the Key Performance Indicator (KPI) dialog box, in **Target** select **Absolute Value**, and then type **1.25**.
- In the left (low) slider field, slide until the field displays **0.8**, and then slide the right (high) slider field, until the field displays **1.03**.
- In **Select Icon Style**, select the diamond (red), triangle (yellow), circle (green) icon type, and then click **OK**.

What's next?

Lesson 8: Create perspectives.

Create perspectives

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create an Internet Sales perspective. A perspective defines a viewable subset of a model that provides focused, business-specific, or application-specific viewpoints. When a user connects to a model by using a perspective, they see only those model objects (tables, columns, measures, hierarchies, and KPIs) as fields defined in that perspective. To learn more, see [Perspectives](#).

The Internet Sales perspective you create in this lesson excludes the DimCustomer table object. When you create a perspective that excludes certain objects from view, that object still exists in the model. However, it is not visible in a reporting client field list. Calculated columns and measures either included in a perspective or not can still calculate from object data that is excluded.

The purpose of this lesson is to describe how to create perspectives and become familiar with the tabular model authoring tools. If you later expand this model to include additional tables, you can create additional perspectives to define different viewpoints of the model, for example, Inventory and Sales.

Estimated time to complete this lesson: **Five minutes**

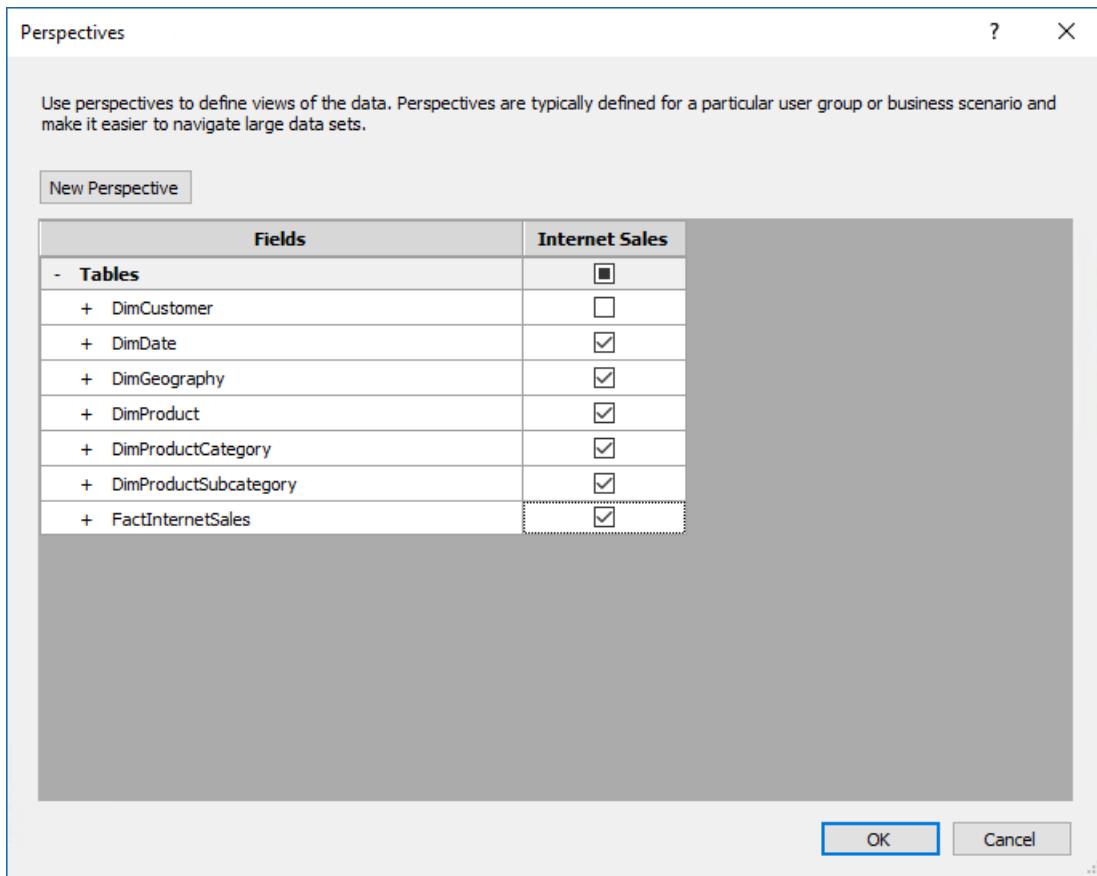

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 7: Create Key Performance Indicators](#).

Create perspectives

To create an Internet Sales perspective

1. Click the **Model** menu > **Perspectives** > **Create and Manage**.
2. In the **Perspectives** dialog box, click **New Perspective**.
3. Double-click the **New Perspective** column heading, and then rename **Internet Sales**.
4. Select the all the tables *except* **DimCustomer**.

In a later lesson, you use the Analyze in Excel feature to test this perspective. The Excel PivotTable Fields List includes each table except the DimCustomer table.

What's next?

[Lesson 9: Create hierarchies.](#)

Create hierarchies

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create hierarchies. Hierarchies are groups of columns arranged in levels. For example, a Geography hierarchy might have sublevels for Country, State, County, and City. Hierarchies can appear separate from other columns in a reporting client application field list, making them easier for client users to navigate and include in a report. To learn more, see [Hierarchies](#)

To create hierarchies, use the model designer in *Diagram View*. Creating and managing hierarchies is not supported in *Data View*.

Estimated time to complete this lesson: **20 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 8: Create perspectives](#).

Create hierarchies

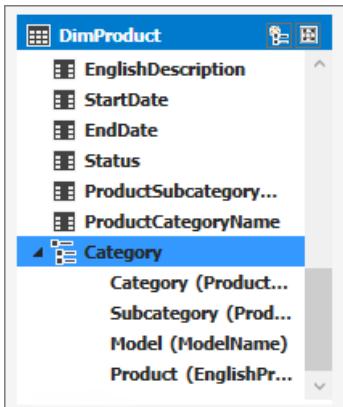

To create a Category hierarchy in the DimProduct table

1. In the model designer (diagram view), right-click the **DimProduct** table > **Create Hierarchy**. A new hierarchy appears at the bottom of the table window. Rename the hierarchy **Category**.
2. Click and drag the **ProductCategoryName** column to the new **Category** hierarchy.
3. In the **Category** hierarchy, right-click **ProductCategoryName** > **Rename**, and then type **Category**.

NOTE

Renaming a column in a hierarchy does not rename that column in the table. A column in a hierarchy is just a representation of the column in the table.

4. Click and drag the **ProductSubcategoryName** column to the **Category** hierarchy. Rename it **Subcategory**.
5. Right-click the **ModelName** column > **Add to hierarchy**, and then select **Category**. Rename it **Model**.
6. Finally, add **EnglishProductName** to the Category hierarchy. Rename it **Product**.

To create hierarchies in the DimDate table

1. In the **DimDate** table, create a hierarchy named **Calendar**.
2. Add the following columns in-order:
 - CalendarYear
 - CalendarSemester
 - CalendarQuarter
 - MonthCalendar
 - DayNumberOfMonth
3. In the **DimDate** table, create a **Fiscal** hierarchy. Include the following columns in-order:
 - FiscalYear
 - FiscalSemester
 - FiscalQuarter
 - MonthCalendar
 - DayNumberOfMonth
4. Finally, in the **DimDate** table, create a **ProductionCalendar** hierarchy. Include the following columns in-order:
 - CalendarYear
 - WeekNumberOfYear
 - DayNumberOfWeek

What's next?

[Lesson 10: Create partitions.](#)

Create partitions

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services (starting with 2017) ✓ Azure Analysis Services ✗ Power BI Premium

In this lesson, you create partitions to divide the FactInternetSales table into smaller logical parts that can be processed (refreshed) independent of other partitions. By default, every table you include in your model has one partition, which includes all the table's columns and rows. For the FactInternetSales table, we want to divide the data by year; one partition for each of the table's five years. Each partition can then be processed independently. To learn more, see [Partitions](#).

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 9: Create Hierarchies](#).

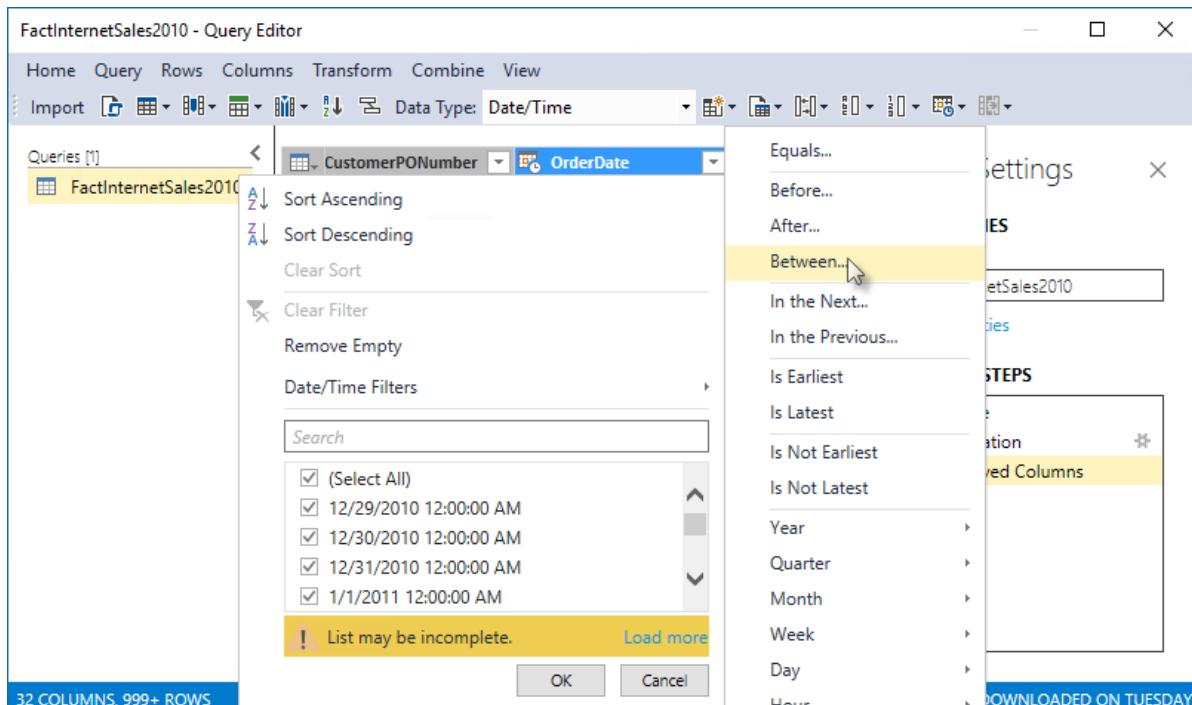

Create partitions

To create partitions in the FactInternetSales table

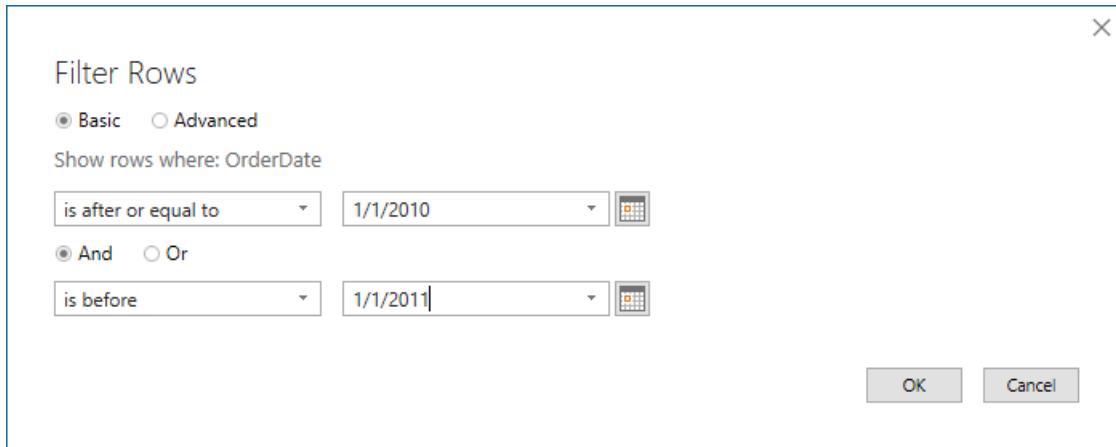

1. In Tabular Model Explorer, expand **Tables**, and then right-click **FactInternetSales** > **Partitions**.
2. In Partition Manager, click **Copy**, and then change the name to **FactInternetSales2010**.

Because you want the partition to include only those rows within a certain period, for the year 2010, you must modify the query expression.

3. Click **Design** to open Query Editor, and then click the **FactInternetSales2010** query.
4. In preview, click the down arrow in the **OrderDate** column heading, and then click **Date/Time Filters** > **Between**.

5. In the Filter Rows dialog box, in **Show rows where: OrderDate**, leave **is after or equal to**, and then in the date field, enter **1/1/2010**. Leave the **And** operator selected, then select **is before**, then in the date field, enter **1/1/2011**, and then click **OK**.

Notice in Query Editor, in APPLIED STEPS, you see another step named Filtered Rows. This filter is to select only order dates from 2010.

6. Click **Import**.

In Partition Manager, notice the query expression now has an additional Filtered Rows clause.

```
let
    Source = #"SQL/owend_dt1;AdventureWorksDW2014",
    dbo_FactInternetSales = Source{[Schema="dbo",Item="FactInternetSales"]}[Data],
    #"Filtered Rows" = Table.SelectRows(dbo_FactInternetSales, each [OrderDate] >= #datetime(2010, 1, 1, 0, 0, 0) and
    [OrderDate] < #datetime(2011, 1, 1, 0, 0, 0))
in
    #"Filtered Rows"
```

This statement specifies this partition should include only the data in those rows where the OrderDate is in the 2010 calendar year as specified in the filtered rows clause.

To create a partition for the 2011 year

1. In the partitions list, click the **FactInternetSales2010** partition you created, and then click **Copy**. Change the partition name to **FactInternetSales2011**.

You do not need to use Query Editor to create a new filtered rows clause. Because you created a copy of the query for 2010, all you need to do is make a slight change in the query for 2011.

2. In **Query Expression**, in-order for this partition to include only those rows for the 2011 year, replace the years in the Filtered Rows clause with **2011** and **2012**, respectively, like:

```
let
    Source = #"SQL/localhost;AdventureWorksDW2014",
    dbo_FactInternetSales = Source{[Schema="dbo",Item="FactInternetSales"]}[Data],
    #"Removed Columns" = Table.RemoveColumns(dbo_FactInternetSales, {"OrderDateKey", "DueDateKey",
    "ShipDateKey"},),
    #"Filtered Rows" = Table.SelectRows(#"Removed Columns", each [OrderDate] >= #datetime(2011, 1, 1,
    0, 0, 0) and [OrderDate] < #datetime(2012, 1, 1, 0, 0, 0))
in
    #"Filtered Rows"
```

To create partitions for 2012, 2013, and 2014.

- Follow the previous steps, creating partitions for 2012, 2013, and 2014, changing the years in the Filtered Rows clause to include only rows for that year.

Delete the FactInternetSales partition

Now that you have partitions for each year, you can delete the FactInternetSales partition; preventing overlap when choosing Process all when processing partitions.

To delete the FactInternetSales partition

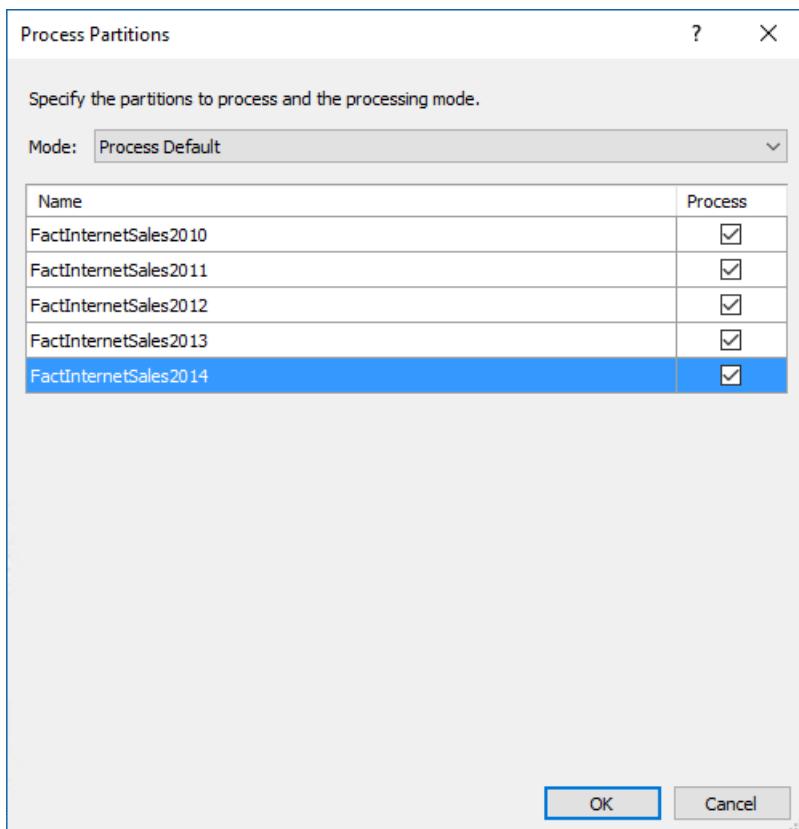

- Click the **FactInternetSales** partition, and then click **Delete**.

Process partitions

In Partition Manager, notice the **Last Processed** column for each of the new partitions you created shows these partitions have never been processed. When you create partitions, you should run a Process Partitions or Process Table operation to refresh the data in those partitions.

To process the FactInternetSales partitions

- Click **OK** to close Partition Manager.
- Click the **FactInternetSales** table, then click the **Model** menu > **Process** > **Process Partitions**.
- In the Process Partitions dialog box, verify **Mode** is set to **Process Default**.
- Select the checkbox in the **Process** column for each of the five partitions you created, and then click **OK**.

If you're prompted for Impersonation credentials, enter the Windows user name and password you specified in Lesson 2.

The **Data Processing** dialog box appears and displays process details for each partition. Notice that a different number of rows for each partition are transferred. Each partition includes only those rows for the year specified in the WHERE clause in the SQL Statement. When processing is finished, go ahead and close the Data Processing dialog box.

Data Processing ? X

Processing Progress

Processing gets updated data from the original data sources.

Success

| Success | | 5 Total | 0 Cancelled |
|---------|-----------------------|-----------------------------------|-------------|
| | | 5 Success | 0 Error |
| | FactInternetSales2010 | Status | Message |
| | FactInternetSales2011 | Success. 14 rows transferred. | |
| | FactInternetSales2012 | Success. 2,216 rows transferred. | |
| | FactInternetSales2013 | Success. 3,397 rows transferred. | |
| | FactInternetSales2014 | Success. 52,801 rows transferred. | |

Details:

Stop Processing Close

What's next?

Go to the next lesson: [Lesson 11: Create Roles](#).

Create roles

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you create roles. Roles provide model database object and data security by limiting access to only those users that are role members. Each role is defined with a single permission: None, Read, Read and Process, Process, or Administrator. Roles can be defined during model authoring by using Role Manager. After a model has been deployed, you can manage roles by using SQL Server Management Studio (SSMS). To learn more, see [Roles](#).

NOTE

Creating roles is not necessary to complete this tutorial. By default, the account you are currently logged in with has Administrator privileges on the model. However, for other users in your organization to browse by using a reporting client, you must create at least one role with Read permissions and add those users as members.

You create three roles:

- **Sales Manager** - This role can include users in your organization for which you want to have Read permission to all model objects and data.
- **Sales Analyst US** - This role can include users in your organization for which you want only to be able to browse data related to sales in the United States. For this role, you use a DAX formula to define a *Row Filter*, which restricts members to browse data only for the United States.
- **Administrator** - This role can include users for which you want to have Administrator permission, which allows unlimited access and permissions to perform administrative tasks on the model database.

Because Windows user and group accounts in your organization are unique, you can add accounts from your particular organization to members. However, for this tutorial, you can also leave the members blank. You test the effect of each role later in Lesson 12: Analyze in Excel.

Estimated time to complete this lesson: **15 minutes**

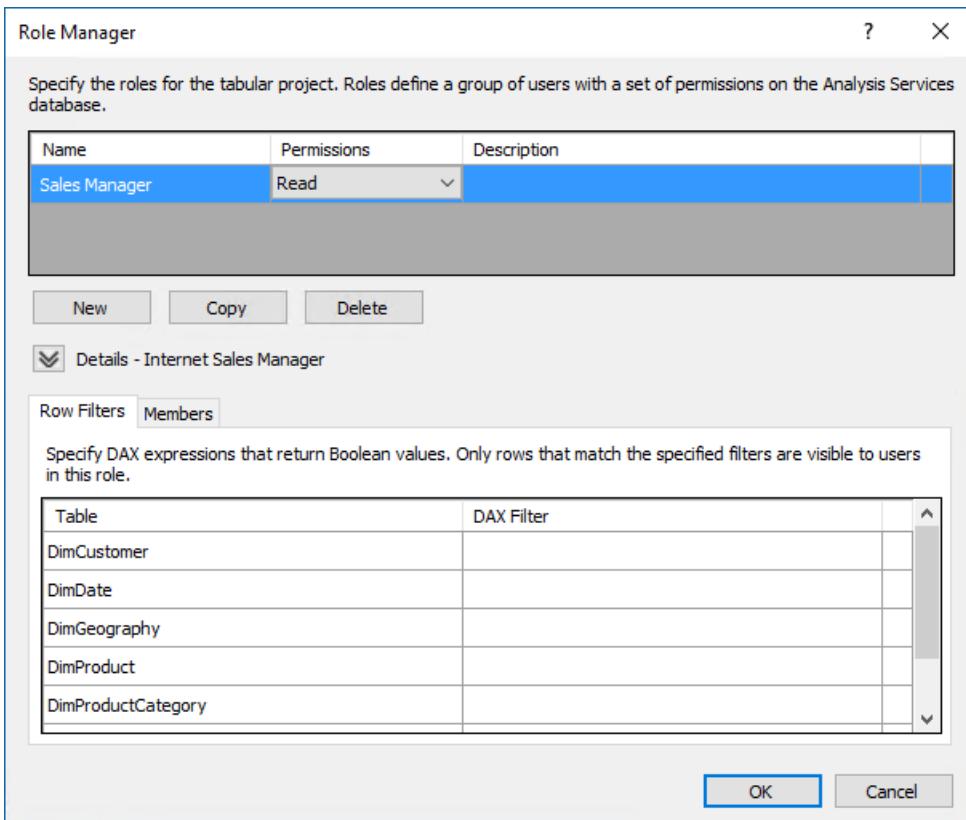

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 10: Create partitions](#).

Create roles

To create a Sales Manager user role

1. In Tabular Model Explorer, right-click **Roles** > **Roles**.
2. In Role Manager, click **New**.
3. Click the new role, and then in the **Name** column, rename the role to **Sales Manager**.
4. In the **Permissions** column, click the dropdown list, and then select the **Read** permission.

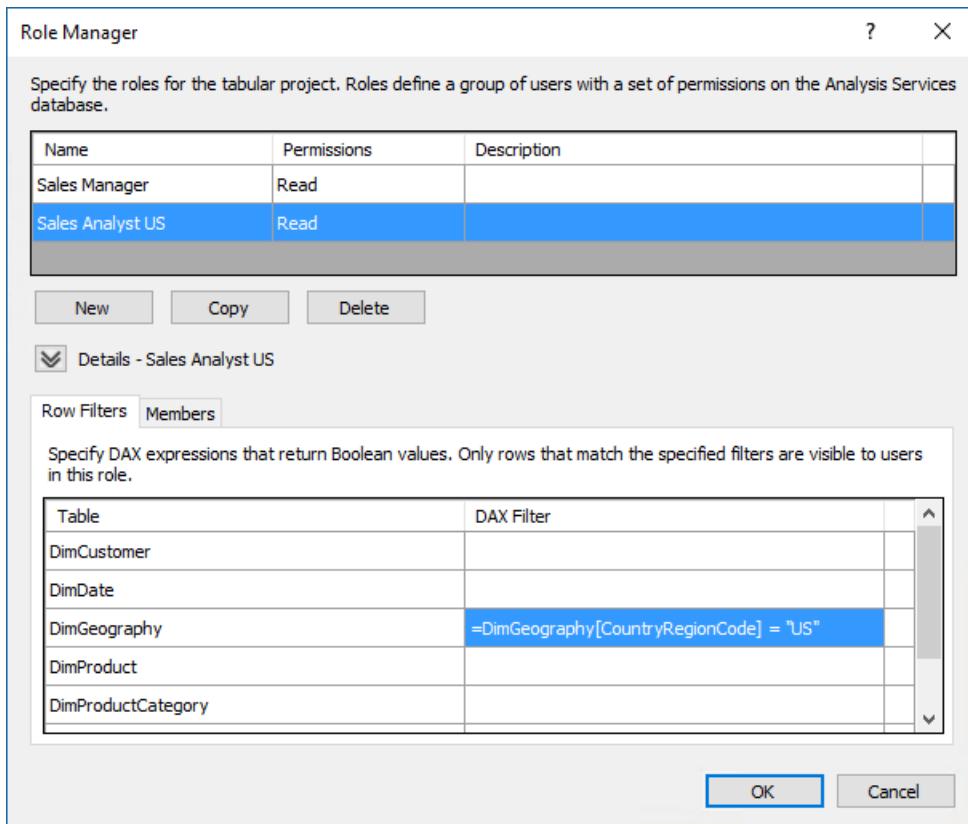

5. Optional: Click the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

To create a **Sales Analyst US** user role

1. In Role Manager, click **New**.
2. Rename the role to **Sales Analyst US**.
3. Give this role **Read** permission.
4. Click the Row Filters tab, and then for the **DimGeography** table only, in the DAX Filter column, type the following formula:

```
=DimGeography[CountryRegionCode] = "US"
```

A Row Filter formula must resolve to a Boolean (TRUE/FALSE) value. With this formula, you are specifying that only rows with the Country Region Code value of "US" are visible to the user.

5. Optional: Click the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

To create an Administrator user role

1. Click **New**.
2. Rename the role to **Administrator**.
3. Give this role **Administrator** permission.
4. Optional: Click the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

What's next?

[Lesson 12: Analyze in Excel.](#)

Analyze in Excel

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you use the Analyze in Excel feature to open Microsoft Excel, automatically create a connection to the model workspace, and automatically add a PivotTable to the worksheet. The Analyze in Excel feature is meant to provide a quick and easy way to test the efficacy of your model design prior to deploying your model. You do not perform any data analysis in this lesson. The purpose of this lesson is to familiarize you, the model author, with the tools you can use to test your model design.

To complete this lesson, Excel must be installed on the same computer as Visual Studio.

Estimated time to complete this lesson: **5 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 11: Create roles](#).

Browse using the Default and Internet Sales perspectives

In these first tasks, you browse your model by using both the default perspective, which includes all model objects, and also by using the Internet Sales perspective you created earlier. The Internet Sales perspective excludes the Customer table object.

To browse by using the Default perspective

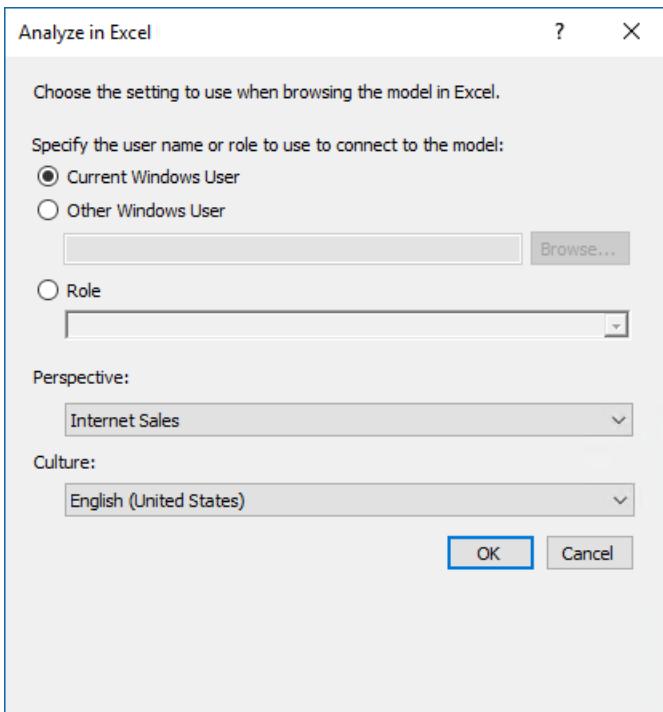

1. Click the **Model** menu > **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, click **OK**.

Excel opens with a new workbook. A data source connection is created using the current user account and the Default perspective is used to define viewable fields. A PivotTable is automatically added to the worksheet.

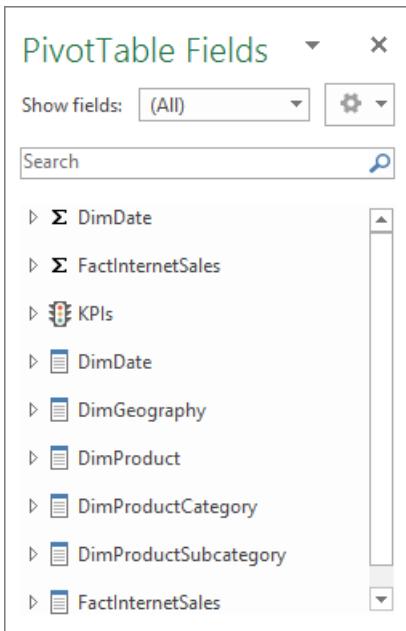

3. In Excel, in the **PivotTable Field List**, notice the **DimDate** and **FactInternetSales** measure groups appear. The **DimCustomer**, **DimDate**, **DimGeography**, **DimProduct**, **DimProductCategory**, **DimProductSubcategory**, and **FactInternetSales** tables with their respective columns also appear.
4. Close Excel without saving the workbook.

To browse by using the Internet Sales perspective

1. Click the **Model** menu, and then click **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, leave **Current Windows User** selected, then in the **Perspective** dropdown listbox, select **Internet Sales**, and then click **OK**.

3. In Excel, in **PivotTable Fields**, notice the DimCustomer table is excluded from the field list.

4. Close Excel without saving the workbook.

Browse by using roles

Roles are an important part of any tabular model. Without at least one role to which users are added as members, users cannot access and analyze data using your model. The Analyze in Excel feature provides a way for you to test the roles you have defined.

To browse by using the Sales Manager user role

1. In SSDT, click the **Model** menu, and then click **Analyze in Excel**.
2. In **Specify the user name or role to use to connect to the model**, select **Role**, and then in the drop-down listbox, select **Sales Manager**, and then click **OK**.

Excel opens with a new workbook. A PivotTable is automatically created. The Pivot Table Field List includes all the data fields available in your new model.

3. Close Excel without saving the workbook.

What's next?

Go to the next lesson: [Lesson 13: Deploy](#).

Deploy

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this lesson, you configure deployment properties; specifying a server to deploy to and a name for the model. You then deploy the model to the server. After your model is deployed, users can connect to it by using a reporting client application. To learn more, see [Deploy to Azure Analysis Services](#) and [Tabular model solution deployment](#).

Estimated time to complete this lesson: **5 minutes**

Prerequisites

This article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 12: Analyze in Excel](#).

IMPORTANT

If deploying to Azure Analysis Services, you must have [Administrator permissions](#) on the server.

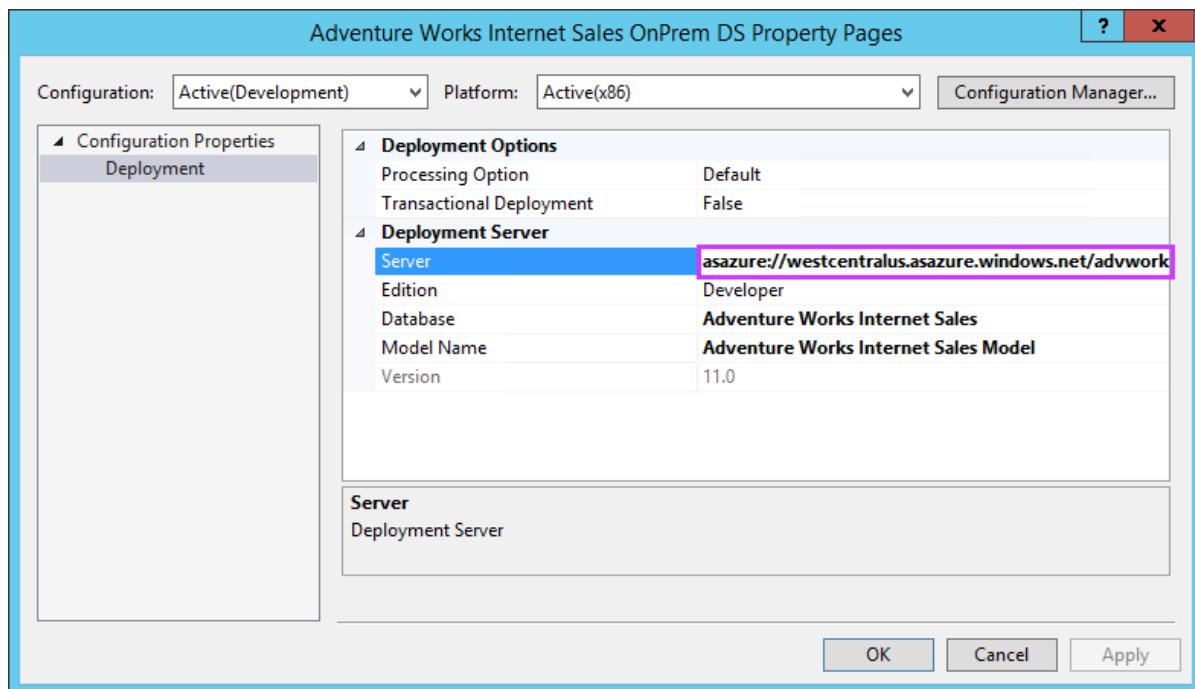

IMPORTANT

If you installed the AdventureWorksDW sample database on an on-premises SQL Server, and you're deploying your model to an Azure Analysis Services server, an [On-premises data gateway](#) is required.

Deploy the model

To configure deployment properties

1. In **Solution Explorer**, right-click the **AW Internet Sales** project, and then click **Properties**.
2. In the **AW Internet Sales Property Pages** dialog box, under **Deployment Server**, in the **Server** property, enter the full server name. If connecting to Azure Analysis Services, server name must include the full URL.

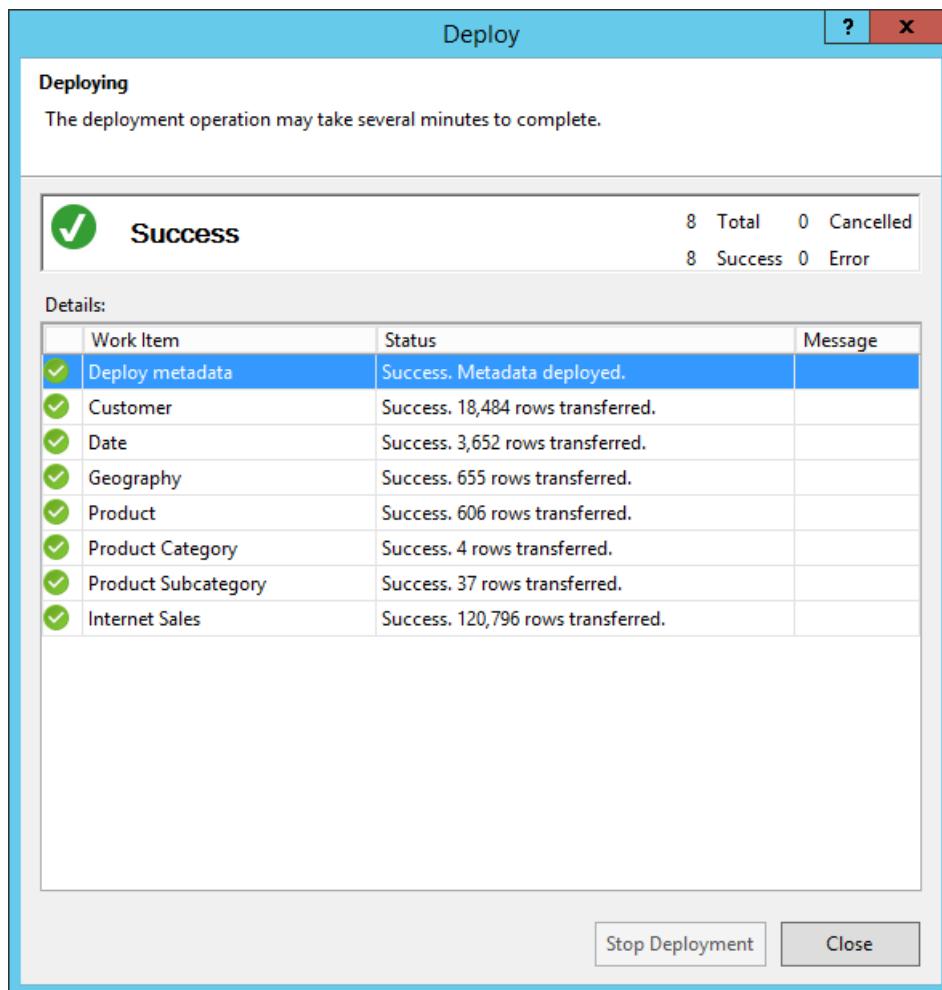

3. In the **Database** property, type **Adventure Works Internet Sales**.
4. In the **Model Name** property, type **Adventure Works Internet Sales Model**.
5. Verify your selections and then click **OK**.

To deploy the Adventure Works Internet Sales

1. In **Solution Explorer**, right-click the **AW Internet Sales** project > **Build**.
2. Right-click the **AW Internet Sales** project > **Deploy**.

When deploying to Azure Analysis Services, you may be prompted to enter your account. Enter your organizational account and password, for example nancy@adventureworks.com. This account must be in Admins on the server.

The Deploy dialog box appears and displays the deployment status of the metadata and each table included in the model.

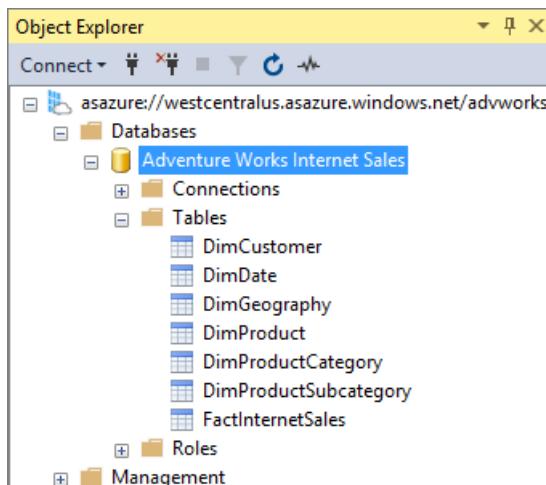

- When deployment successfully completes, go ahead and click **Close**.

This lesson describes the most common and easiest method to deploy a tabular model from SSDT. Advanced deployment options such as the Deployment Wizard or automating with XMLA and AMO provide greater flexibility, consistency, and scheduled deployments. To learn more, see [Tabular model solution deployment](#).

Conclusion

Congratulations! You're finished authoring and deploying your first Analysis Services Tabular model. This tutorial has helped guide you through completing the most common tasks in creating a tabular model. Now that your Adventure Works Internet Sales model is deployed, you can use SQL Server Management Studio to manage the model; create process scripts and a backup plan. Users can also now connect to the model using a reporting client application such as Microsoft Excel or Power BI.

What's next?

- [Connect with Power BI Desktop](#)
- [Supplemental Lesson - Dynamic security](#)
- [Supplemental Lesson - Detail rows](#)
- [Supplemental Lesson - Ragged hierarchies](#)

Supplemental lesson - Detail Rows

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this supplemental lesson, you use the DAX Editor to define a custom Detail Rows Expression. A Detail Rows Expression is a property on a measure, providing end-users more information about the aggregated results of a measure.

Estimated time to complete this lesson: **10 minutes**

Prerequisites

This supplemental lesson article is part of a tabular modeling tutorial. Before performing the tasks in this supplemental lesson, you should have completed all previous lessons or have a completed Adventure Works Internet Sales sample model project.

What's the issue?

Let's look at the details of the InternetTotalSales measure, before adding a Detail Rows Expression.

1. In SSDT, click the **Model** menu > **Analyze in Excel** to open Excel and create a blank PivotTable.
2. In **PivotTable Fields**, add the **InternetTotalSales** measure from the FactInternetSales table to **Values**, **CalendarYear** from the DimDate table to **Columns**, and **EnglishCountryRegionName** to **Rows**. The PivotTable now gives an aggregated results from the InternetTotalSales measure by regions and year.

| | A | B | C | D | E | F | G |
|---|--------------------|---------------|----------------|----------------|-----------------|-------------|-----------------|
| 1 | InternetTotalSales | Column Labels | | | | | |
| 2 | Row Labels | 2010 | 2011 | 2012 | 2013 | 2014 | Grand Total |
| 3 | Australia | \$20,909.78 | \$2,563,732.25 | \$2,128,407.46 | \$4,339,443.38 | \$8,507.72 | \$9,061,000.58 |
| 4 | Canada | \$3,578.27 | \$571,571.80 | \$307,604.52 | \$1,085,632.65 | \$9,457.62 | \$1,977,844.86 |
| 5 | France | \$3,399.99 | \$410,845.33 | \$648,065.54 | \$1,578,511.80 | \$3,195.06 | \$2,644,017.71 |
| 6 | Germany | | \$520,500.16 | \$608,657.98 | \$1,761,876.36 | \$3,277.83 | \$2,894,312.34 |
| 7 | United Kingdom | \$699.10 | \$550,591.22 | \$712,700.96 | \$2,124,007.29 | \$3,713.64 | \$3,391,712.21 |
| 8 | United States | \$14,833.90 | \$2,458,285.17 | \$1,437,048.73 | \$5,462,078.86 | \$17,542.85 | \$9,389,789.51 |
| 9 | Grand Total | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 | \$29,358,677.22 |

3. In the PivotTable, double-click an aggregated value for a year and a region name. Here we double-clicked the value for Australia and the year 2014. A new sheet opens containing data, but not useful data.

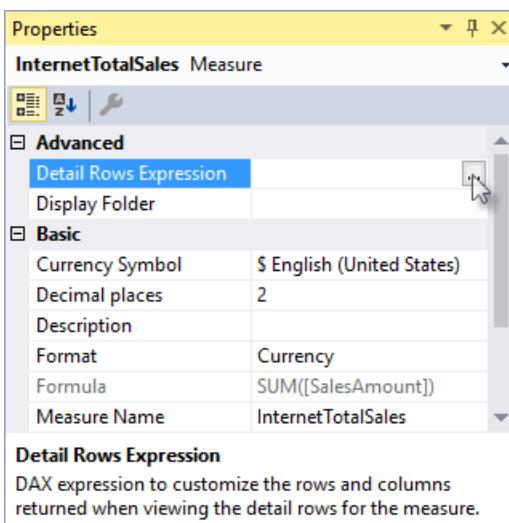

| A1 | B | C | D |
|--|--|--------------------------------|--------------------------------------|
| Data returned for InternetTotalSales, Australia, 2014 (First 1000 rows). | | | |
| 1 | Data returned for InternetTotalSales, Australia, 2014 (First 1000 rows). | | |
| 2 | | | |
| 3 | FactInternetSales[PromotionKey] | FactInternetSales[CurrencyKey] | FactInternetSales[SalesTerritoryKey] |
| 4 | 1 | 100 | 9 SO74417 |
| 5 | 1 | 100 | 9 SO74506 |
| 6 | 1 | 100 | 9 SO74653 |
| 7 | 1 | 100 | 9 SO74721 |
| 8 | 1 | 100 | 9 SO74757 |
| 9 | 1 | 100 | 9 SO74795 |
| 10 | 1 | 100 | 9 SO74812 |
| 11 | 1 | 100 | 9 SO74845 |
| 12 | 1 | 100 | 9 SO74874 |
| 13 | 1 | 100 | 9 SO74876 |
| 14 | 1 | 100 | 9 SO74938 |
| 15 | 1 | 100 | 9 SO74969 |
| 16 | 1 | 100 | 9 SO75032 |
| 17 | 1 | 100 | 9 SO75090 |
| 18 | 1 | 100 | 9 SO74252 |

What we want to see here is a table containing columns and rows of data that contribute to the aggregated result of the InternetTotalSales measure. To do that, we can add a Detail Rows Expression as a property of the measure.

Add a Detail Rows Expression

To create a Detail Rows Expression

1. In the FactInternetSales table's measure grid, click the **InternetTotalSales** measure.
2. In **Properties > Detail Rows Expression**, click the editor button to open the DAX Editor.

3. In DAX Editor, enter the following expression:

```
SELECTCOLUMNS(
    FactInternetSales,
    "Sales Order Number", FactInternetSales[SalesOrderNumber],
    "Customer First Name", RELATED(DimCustomer[FirstName]),
    "Customer Last Name", RELATED(DimCustomer[LastName]),
    "City", RELATED(DimGeography[City]),
    "Order Date", FactInternetSales[OrderDate],
    "Internet Total Sales", [InternetTotalSales]
)
```

This expression specifies names, columns, and measure results from the FactInternetSales table and related tables are returned when a user double-clicks an aggregated result in a PivotTable or report.

4. Back in Excel, delete the sheet created in Step 3, then double-click an aggregated value. This time, with a Detail Rows Expression property defined for the measure, a new sheet opens containing a lot more useful

data.

| J5 | A | B | C | D | E | F | G |
|----|--|-----------------------|----------------------|---------------|--------------|------------------------|---|
| 1 | Data returned for InternetTotalSales, Australia, 2014 (First 1000 rows). | | | | | | |
| 3 | [Sales Order Number] | [Customer First Name] | [Customer Last Name] | [City] | [Order Date] | [Internet Total Sales] | |
| 4 | S074417 | Roger | Zhang | Sydney | 1/6/2014 | 4.99 | |
| 5 | S074506 | Joy | Gutierrez | Perth | 1/9/2014 | 4.99 | |
| 6 | S074653 | Chad | Raje | Melbourne | 1/14/2014 | 4.99 | |
| 7 | S074721 | Candace | Srini | North Ryde | 1/16/2014 | 4.99 | |
| 8 | S074757 | Roger | Sun | Rockhampton | 1/17/2014 | 4.99 | |
| 9 | S074795 | Bianca | Liu | Springwood | 1/18/2014 | 4.99 | |
| 10 | S074812 | Angel | Evans | Sunbury | 1/19/2014 | 4.99 | |
| 11 | S074845 | Jamie | Zhu | Findon | 1/20/2014 | 4.99 | |
| 12 | S074874 | Erick | Suri | Coffs Harbour | 1/21/2014 | 4.99 | |
| 13 | S074876 | Nina | Raje | Townsville | 1/21/2014 | 4.99 | |
| 14 | S074938 | Kellie | Blanco | East Brisbane | 1/23/2014 | 4.99 | |
| 15 | S074969 | Byron | Navarro | Newcastle | 1/24/2014 | 4.99 | |
| 16 | S075032 | Isaac | Phillips | Sydney | 1/26/2014 | 4.99 | |
| 17 | S075090 | Vincent | Zhang | Lane Cove | 1/28/2014 | 4.99 | |

5. Redeploy your model.

[Supplemental lesson - Dynamic security](#)

[Supplemental lesson - Ragged hierarchies](#)

Supplemental lesson - Dynamic security

7/16/2019 • 9 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this supplemental lesson, you create an additional role that implements dynamic security. Dynamic security provides row-level security based on the user name or login id of the user currently logged on.

To implement dynamic security, you add a table to your model containing the user names of those users that can connect to the model and browse model objects and data. The model you create using this tutorial is in the context of Adventure Works; however, to complete this lesson, you must add a table containing users from your own domain. You do not need the passwords for the user names that are added. To create an EmployeeSecurity table, with a small sample of users from your own domain, you use the Paste feature, pasting employee data from an Excel spreadsheet. In a real-world scenario, the table containing user names would typically be a table from an actual database as a data source; for example, a real DimEmployee table.

To implement dynamic security, you use two DAX functions: [USERNAME Function \(DAX\)](#) and [LOOKUPVALUE Function \(DAX\)](#). These functions, applied in a row filter formula, are defined in a new role. By using the LOOKUPVALUE function, the formula specifies a value from the EmployeeSecurity table. The formula then passes that value to the USERNAME function, which specifies the user name of the user logged on belongs to this role. The user can then browse only data specified by the role's row filters. In this scenario, you specify that sales employees can only browse Internet sales data for the sales territories in which they are a member.

Those tasks that are unique to this Adventure Works tabular model scenario, but would not necessarily apply to a real-world scenario are identified as such. Each task includes additional information describing the purpose of the task.

Estimated time to complete this lesson: **30 minutes**

Prerequisites

This supplemental lesson article is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this supplemental lesson, you should have completed all previous lessons.

Add the DimSalesTerritory table to the AW Internet Sales Tabular Model Project

To implement dynamic security for this Adventure Works scenario, you must add two additional tables to your model. The first table you add is DimSalesTerritory (as Sales Territory) from the same AdventureWorksDW database. You later apply a row filter to the SalesTerritory table that defines the particular data the logged on user can browse.

To add the DimSalesTerritory table

1. In Tabular Model Explorer > **Data Sources**, right-click your connection, and then click **Import New Tables**.

If the Impersonation Credentials dialog box appears, type the impersonation credentials you used in Lesson 2: Add Data.

2. In Navigator, select the **DimSalesTerritory** table, and then click **OK**.
3. In Query Editor, click the **DimSalesTerritory** query, and then remove **SalesTerritoryAlternateKey**

column.

4. Click **Import**.

The new table is added to the model workspace. Objects and data from the source DimSalesTerritory table are then imported into your AW Internet Sales Tabular Model.

5. After the table has been imported successfully, click **Close**.

Add a table with user name data

The DimEmployee table in the AdventureWorksDW sample database contains users from the AdventureWorks domain. Those user names do not exist in your own environment. You must create a table in your model that contains a small sample (at least three) of actual users from your organization. You then add these users as members to the new role. You do not need the passwords for the sample user names, but you do need actual Windows user names from your own domain.

To add an EmployeeSecurity table

1. Open Microsoft Excel, creating a worksheet.
2. Copy the following table, including the header row, and then paste it into the worksheet.

| EmployeeId | SalesTerritoryId | FirstName | LastName | LoginId |
|---|------------------|-----------|----------|---------|
| 1 2 <user first name> <user last name> \<domain\username> | | | | |
| 1 3 <user first name> <user last name> \<domain\username> | | | | |
| 2 4 <user first name> <user last name> \<domain\username> | | | | |
| 3 5 <user first name> <user last name> \<domain\username> | | | | |

3. Replace the first name, last name, and domain\username with the names and login ids of three users in your organization. Put the same user on the first two rows, for EmployeeId 1, showing this user belongs to more than one sales territory. Leave the EmployeeId and SalesTerritoryId fields as they are.
4. Save the worksheet as **SampleEmployee**.
5. In the worksheet, select all the cells with employee data, including the headers, then right-click the selected data, and then click **Copy**.
6. In SSDT, click the **Edit** menu, and then click **Paste**.
If Paste is grayed out, click any column in any table in the model designer window, and try again.
7. In the **Paste Preview** dialog box, in **Table Name**, type **EmployeeSecurity**.
8. In **Data to be pasted**, verify the data includes all the user data and headers from the SampleEmployee worksheet.
9. Verify **Use first row as column headers** is checked, and then click **Ok**.

A new table named EmployeeSecurity with employee data copied from the SampleEmployee worksheet is created.

Create relationships between FactInternetSales, DimGeography, and DimSalesTerritory table

The FactInternetSales, DimGeography, and DimSalesTerritory table all contain a common column, SalesTerritoryId. The SalesTerritoryId column in the DimSalesTerritory table contains values with a different Id for each sales territory.

To create relationships between the FactInternetSales, DimGeography, and the DimSalesTerritory table

1. In Diagram View, in the **DimGeography** table, click, and hold on the **SalesTerritoryId** column, then drag the cursor to the **SalesTerritoryId** column in the **DimSalesTerritory** table, and then release.
2. In the **FactInternetSales** table, click, and hold on the **SalesTerritoryId** column, then drag the cursor to the **SalesTerritoryId** column in the **DimSalesTerritory** table, and then release.

Notice the Active property for this relationship is False, meaning it's inactive. The FactInternetSales table already has another active relationship.

Hide the EmployeeSecurity Table from client applications

In this task, you hide the EmployeeSecurity table, keeping it from appearing in a client application's field list. Keep in mind that hiding a table does not secure it. Users can still query EmployeeSecurity table data if they know how. To secure the EmployeeSecurity table data, preventing users from being able to query any of its data, you apply a filter in a later task.

To hide the EmployeeSecurity table from client applications

- In the model designer, in Diagram View, right-click the **Employee** table heading, and then click **Hide from Client Tools**.

Create a Sales Employees by Territory user role

In this task, you create a user role. This role includes a row filter defining which rows of the DimSalesTerritory table are visible to users. The filter is then applied in the one-to-many relationship direction to all other tables related to DimSalesTerritory. You also apply a filter that secures the entire EmployeeSecurity table from being queryable by any user that is a member of the role.

NOTE

The Sales Employees by Territory role you create in this lesson restricts members to browse (or query) only sales data for the sales territory to which they belong. If you add a user as a member to the Sales Employees by Territory role that also exists as a member in a role created in [Lesson 11: Create Roles](#), you get a combination of permissions. When a user is a member of multiple roles, the permissions, and row filters defined for each role are cumulative. That is, the user has the greater permissions determined by the combination of roles.

To create a Sales Employees by Territory user role

1. In SSDT, click the **Model** menu, and then click **Roles**.
2. In **Role Manager**, click **New**.

A new role with the None permission is added to the list.

3. Click the new role, and then in the **Name** column, rename the role to **Sales Employees by Territory**.
4. In the **Permissions** column, click the dropdown list, and then select the **Read** permission.
5. Click the **Members** tab, and then click **Add**.
6. In the **Select User or Group** dialog box, in **Enter the object named to select**, type the first sample user name you used when creating the EmployeeSecurity table. Click **Check Names** to verify the user name is valid, and then click **Ok**.

Repeat this step, adding the other sample user names you used when creating the EmployeeSecurity table.

7. Click the **Row Filters** tab.
8. For the **EmployeeSecurity** table, in the **DAX Filter** column, type the following formula:

```
=FALSE()
```

This formula specifies that all columns resolve to the false Boolean condition. No columns for the EmployeeSecurity table can be queried by a member of the Sales Employees by Territory user role.

9. For the **DimSalesTerritory** table, type the following formula:

```
= 'DimSalesTerritory'[SalesTerritoryKey]=LOOKUPVALUE('EmployeeSecurity'[SalesTerritoryId],  
'EmployeeSecurity'[LoginId], USERNAME(),  
'EmployeeSecurity'[SalesTerritoryId], 'DimSalesTerritory'[SalesTerritoryKey])
```

In this formula, the LOOKUPVALUE function returns all values for the DimEmployeeSecurity[SalesTerritoryId] column, where the EmployeeSecurity[LoginId] is the same as the current logged on Windows user name, and EmployeeSecurity[SalesTerritoryId] is the same as the DimSalesTerritory[SalesTerritoryId].

The set of sales territory IDs returned by LOOKUPVALUE is then used to restrict the rows shown in the DimSalesTerritory table. Only rows where the SalesTerritoryID for the row is in the set of IDs returned by the LOOKUPVALUE function are displayed.

10. In Role Manager, click **Ok**.

Test the Sales Employees by Territory User Role

In this task, you use the Analyze in Excel feature in SSDT to test the efficacy of the Sales Employees by Territory user role. You specify one of the user names you added to the EmployeeSecurity table and as a member of the role. This user name is then used as the effective user name in the connection created between Excel and the model.

To test the Sales Employees by Territory user role

1. In SSDT, click the **Model** menu, and then click **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, in **Specify the user name or role to use to connect to the model**, select **Other Windows User**, and then click **Browse**.
3. In the **Select User or Group** dialog box, in **Enter the object name to select**, type a user name you included in the EmployeeSecurity table, and then click **Check Names**.
4. Click **Ok** to close the **Select User or Group** dialog box, and then click **Ok** to close the **Analyze in Excel** dialog box.

Excel opens with a new workbook. A PivotTable is automatically created. The PivotTable Fields list includes most of the data fields available in your new model.

Notice the EmployeeSecurity table is not visible in the PivotTable Fields list. You hid this table from client tools in a previous task.

5. In the **Fields** list, in **Σ Internet Sales** (measures), select the **InternetTotalSales** measure. The measure is entered into the **Values** fields.
6. Select the **SalesTerritoryId** column from the **DimSalesTerritory** table. The column is entered into the **Row Labels** fields.

Notice Internet sales figures appear only for the one region to which the effective user name you used belongs. If you select another column, like City from the DimGeography table as Row Label field, only cities in the sales territory to which the effective user belongs are displayed.

This user cannot browse or query any Internet sales data for territories other than the one they belong to.

This restriction is because the row filter defined for the DimSalesTerritory table, in the Sales Employees by Territory user role, secures data for all data related to other sales territories.

- [LOOKUPVALUE Function \(DAX\)](#)
- [CUSTOMDATA Function \(DAX\)](#)

Supplemental lesson - Ragged hierarchies

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

In this supplemental lesson, you resolve a common problem when pivoting on hierarchies that contain blank values (members) at different levels. For example, an organization where a high-level manager has both departmental managers and non-managers as direct reports. Or, geographic hierarchies composed of Country-Region-City, where some cities lack a parent State or Province, such as Washington D.C., Vatican City. When a hierarchy has blank members, it often descends to different, or ragged, levels.

| Employee | ResellerTotalSales |
|----------------------------|--------------------|
| Ken J Sánchez | \$80,450,596.98 |
| Brian S Welcker | \$80,450,596.98 |
| Amy E Alberts | \$15,535,946.26 |
| \$732,078.44 | \$732,078.44 |
| \$732,078.44 | |
| Jae B Pak | \$8,503,338.65 |
| \$8,503,338.65 | |
| Rachel B Valdez | \$1,790,640.23 |
| \$1,790,640.23 | |
| Ranjit R Varkey Chudukatil | \$4,509,888.93 |
| \$4,509,888.93 | |
| Stephen Y Jiang | \$63,320,315.35 |

Tabular models at the 1400 compatibility level have an additional **Hide Members** property for hierarchies. The **Default** setting assumes there are no blank members at any level. The **Hide blank members** setting excludes blank members from the hierarchy when added to a PivotTable or report.

Estimated time to complete this lesson: **20 minutes**

Prerequisites

This supplemental lesson article is part of a tabular modeling tutorial. Before performing the tasks in this supplemental lesson, you should have completed all previous lessons or have a completed Adventure Works Internet Sales sample model project.

If you've created the AW Internet Sales project as part of the tutorial, your model does not yet contain any data or hierarchies that are ragged. To complete this supplemental lesson, you first have to create the problem by adding some additional tables, create relationships, calculated columns, a measure, and a new Organization hierarchy. That part takes about 15 minutes. Then, you get to solve it in just a few minutes.

Add tables and objects

To add new tables to your model

1. In Tabular Model Explorer, expand **Data Sources**, then right-click your connection > **Import New Tables**.
2. In Navigator, select **DimEmployee** and **FactResellerSales**, and then click **OK**.
3. In Query Editor, click **Import**
4. Create the following [relationships](#):

| TABLE 1 | COLUMN | FILTER DIRECTION | TABLE 2 | COLUMN | ACTIVE |
|-------------------|--------------|------------------|-------------|-------------|--------|
| FactResellerSales | OrderDateKey | Default | DimDate | Date | Yes |
| FactResellerSales | DueDate | Default | DimDate | Date | No |
| FactResellerSales | ShipDateKey | Default | DimDate | Date | No |
| FactResellerSales | ProductKey | Default | DimProduct | ProductKey | Yes |
| FactResellerSales | EmployeeKey | To Both Tables | DimEmployee | EmployeeKey | Yes |

5. In the **DimEmployee** table, create the following [calculated columns](#):

Path

```
=PATH([EmployeeKey], [ParentEmployeeKey])
```

FullName

```
=[FirstName] & " " & [MiddleName] & " " & [LastName]
```

Level1

```
=LOOKUPVALUE(DimEmployee[FullName], DimEmployee[EmployeeKey], PATHITEM([Path], 1, 1))
```

Level2

```
=LOOKUPVALUE(DimEmployee[FullName], DimEmployee[EmployeeKey], PATHITEM([Path], 2, 1))
```

Level3

```
=LOOKUPVALUE(DimEmployee[FullName], DimEmployee[EmployeeKey], PATHITEM([Path], 3, 1))
```

Level4

```
=LOOKUPVALUE(DimEmployee[FullName], DimEmployee[EmployeeKey], PATHITEM([Path], 4, 1))
```

Level5

```
=LOOKUPVALUE(DimEmployee[FullName], DimEmployee[EmployeeKey], PATHITEM([Path], 5, 1))
```

6. In the **DimEmployee** table, create a [hierarchy](#) named **Organization**. Add the following columns in-order:

Level1, Level2, Level3, Level4, Level5.

7. In the **FactResellerSales** table, create the following measure:

```
ResellerTotalSales:=SUM([SalesAmount])
```

8. Use [Analyze in Excel](#) to open Excel and automatically create a PivotTable.

9. In **PivotTable Fields**, add the **Organization** hierarchy from the **DimEmployee** table to **Rows**, and the **ResellerTotalSales** measure from the **FactResellerSales** table to **Values**.

The screenshot shows the Microsoft Power BI Data Explorer interface. On the left, the 'PivotTable Fields' pane is open, showing the 'Organization' hierarchy under the 'DimEmployee' table. The 'Rows' section is set to 'Organization', and the 'Values' section is set to 'ResellerTotalSales'. On the right, a PivotTable is displayed in Excel, showing sales data by employee and organization. The PivotTable shows various employees with their total sales, and the 'Organization' hierarchy is visible as a ragged list of members under each employee row.

| A | B | C | D |
|------------------------------|--------------------|---|---|
| 1 Employee | ResellerTotalSales | | |
| 2 Ken J Sánchez | \$80,450,596.98 | | |
| 3 Brian S Welcker | \$80,450,596.98 | | |
| 4 Amy E Alberts | \$15,535,946.26 | | |
| | \$732,078.44 | | |
| 5 Jae B Pak | \$8,503,338.65 | | |
| | \$8,503,338.65 | | |
| 6 Rachel B Valdez | \$1,790,640.23 | | |
| | \$1,790,640.23 | | |
| 7 Ranjit R Varkey Chudukatil | \$4,509,888.93 | | |
| | \$4,509,888.93 | | |
| 12 Stephen Y Jiang | \$63,320,315.35 | | |
| | \$1,092,123.86 | | |
| 14 David R Campbell | \$3,729,945.35 | | |
| | \$3,729,945.35 | | |
| 16 Garrett R Vargas | \$3,609,447.22 | | |
| | \$3,609,447.22 | | |
| 18 Jillian Carson | \$10,065,803.54 | | |

As you can see in the PivotTable, the hierarchy displays rows that are ragged. There are many rows where blank members are shown.

To fix the ragged hierarchy by setting the Hide members property

1. In **Tabular Model Explorer**, expand **Tables > DimEmployee > Hierarchies > Organization**.
2. In **Properties > Hide Members**, select **Hide blank members**.

The screenshot shows the 'Tabular Model Explorer' interface. The 'Properties' pane is open, showing the 'Organization Hierarchy' settings. A pink arrow points to the 'Hide Members' dropdown menu, which is currently set to 'Hide blank members'. Other options in the menu include 'Display Folder' and 'Advanced'.

3. Back in Excel, refresh the PivotTable.

The screenshot shows a Microsoft Excel spreadsheet with a PivotTable Fields ribbon open on the right side. The main table displays employee names in column A and their total sales in column B. The PivotTable Fields ribbon allows for filtering by organization. The data is as follows:

| A | B |
|----------------------------|--------------------|
| Employee | ResellerTotalSales |
| Ken J Sánchez | \$80,450,596.98 |
| Brian S Welcker | \$80,450,596.98 |
| Amy E Alberts | \$15,535,946.26 |
| Jae B Pak | \$8,503,338.65 |
| Rachel B Valdez | \$1,790,640.23 |
| Ranjit R Varkey Chudukatil | \$4,509,888.93 |
| Stephen Y Jiang | \$63,320,315.35 |
| David R Campbell | \$3,729,945.35 |
| Garrett R Vargas | \$3,609,447.22 |
| Jillian Carson | \$10,065,803.54 |
| José Edvaldo Saraiva | \$5,926,418.36 |
| Linda C Mitchell | \$10,367,007.43 |
| Michael G Blythe | \$9,293,903.01 |
| Pamela O Ansman-Wolfe | \$3,325,102.60 |
| Shu K Ito | \$6,427,005.56 |
| Tete A Mensa-Annan | \$2,312,545.69 |
| Tsvi Michael Reiter | \$7,171,012.75 |

Now that looks a whole lot better!

Adventure Works Internet Sales tutorial (1200)

10/22/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

This tutorial provides lessons on how to create an Analysis Services tabular model at the [1200 compatibility level](#) by using Visual Studio, and deploy your model to an Analysis Services server on-premises or in Azure.

If you're using SQL Server 2017 or Azure Analysis Services and you want to create your model at the 1400 compatibility level, use the [Tabular modeling \(1400 compatibility level\)](#). This updated version uses the modern Get Data feature to connect and import source data, uses the M language to configure partitions, and includes additional supplemental lessons.

IMPORTANT

You should create your tabular models at the latest compatibility level supported by your server. Later compatibility level models provide improved performance, additional features, and will upgrade to future compatibility levels more seamlessly.

What you learn

- How to create a new tabular model project in Visual Studio.
- How to import data from a SQL Server relational database into a tabular model project.
- How to create and manage relationships between tables in the model.
- How to create and manage calculations, measures, and Key Performance Indicators that help users analyze model data.
- How to create and manage perspectives and hierarchies that help users more easily browse model data by providing business and application-specific viewpoints.
- How to create partitions dividing table data into smaller logical parts, that can be processed independent from other partitions.
- How to secure model objects and data by creating roles with user members.
- How to deploy a tabular model to an Analysis Services server on-premises or in Azure.

Scenario

This tutorial is based on Adventure Works Cycles, a fictitious company. Adventure Works is a large, multinational manufacturing company that produces bicycles, parts, and accessories for commercial markets in North America, Europe, and Asia. With headquarters in Bothell, Washington, the company employs 500 workers. Additionally, Adventure Works employs several regional sales teams throughout its market base.

To better support the data analysis needs of sales and marketing teams and of senior management, you are tasked with creating a tabular model for users to analyze Internet sales data in the AdventureWorksDW sample database.

In order to complete the tutorial, and the Adventure Works Internet Sales tabular model, you must complete a number of lessons. In each lesson is a number of tasks; completing each task in order is necessary for completing the lesson. While in a particular lesson there may be several tasks that accomplish a similar outcome, but how you

complete each task is slightly different. This is to show that there is often more than one way to complete a particular task, and to challenge you by using skills you've learned in previous tasks.

The purpose of the lessons is to guide you through authoring a basic tabular model running in In-Memory mode by using many of the features included in Visual Studio. Because each lesson builds upon the previous lesson, you should complete the lessons in order. Once you've completed all of the lessons, you have authored and deployed the Adventure Works Internet Sales sample tabular model on an Analysis Services server.

This tutorial does not provide lessons or information about managing a deployed tabular model database by using SQL Server Management Studio, or using a reporting client application to connect to a deployed model to browse model data.

Prerequisites

In order to complete this tutorial, you need the following prerequisites:

- The latest version of [Visual Studio](#) with Analysis Services projects extension.
- The latest version of [SQL Server Management Studio](#).
- A client application such as [Power BI Desktop](#) or Excel.
- A SQL Server instance with the Adventure Works DW sample database. This sample database includes the data necessary to complete this tutorial. [Get the latest version](#).
- An Azure Analysis Services or SQL Server 2016 or later Analysis Services instance to deploy your model to. [Sign up for a free Azure Analysis Services trial](#).

Lessons

This tutorial includes the following lessons:

| LESSON | ESTIMATED TIME TO COMPLETE |
|--|----------------------------|
| Lesson 1: Create a New Tabular Model Project | 10 minutes |
| Lesson 2: Add Data | 20 minutes |
| Lesson 3: Mark as Date Table | 3 minutes |
| Lesson 4: Create Relationships | 10 minutes |
| Lesson 5: Create Calculated Columns | 15 minutes |
| Lesson 6: Create Measures | 30 minutes |
| Lesson 7: Create Key Performance Indicators | 15 minutes |
| Lesson 8: Create Perspectives | 5 minutes |
| Lesson 9: Create Hierarchies | 20 minutes |
| Lesson 10: Create Partitions | 15 minutes |
| Lesson 11: Create Roles | 15 minutes |

| LESSON | ESTIMATED TIME TO COMPLETE |
|---|----------------------------|
| Lesson 12: Analyze in Excel | 20 minutes |
| Lesson 13: Deploy | 5 minutes |

Supplemental lessons

This tutorial also includes Supplemental Lessons. Topics in this section are not required to complete the tutorial, but can be helpful in better understanding advanced tabular model authoring features.

| LESSON | ESTIMATED TIME TO COMPLETE |
|---|----------------------------|
| Implement Dynamic Security by Using Row Filters | 30 minutes |

Next steps

To begin the tutorial, continue to the first lesson: [Lesson 1: Create a New Tabular Model Project](#).

Lesson 1: Create a New Tabular Model Project

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create a new, blank tabular model project in Visual Studio with Analysis Services projects. Once your new project is created, you can begin adding data by using the Table Import Wizard. This lesson also gives you a brief introduction to the tabular model authoring environment in SSDT.

Estimated time to complete this lesson: **10 minutes**

Prerequisites

This topic is the first lesson in a tabular model authoring tutorial. To complete this lesson, you must have the AdventureWorksDW sample database installed on a SQL Server instance. To learn more, see [Tabular Modeling \(Adventure Works Tutorial\)](#).

Create a new tabular model project

To create a new tabular model project

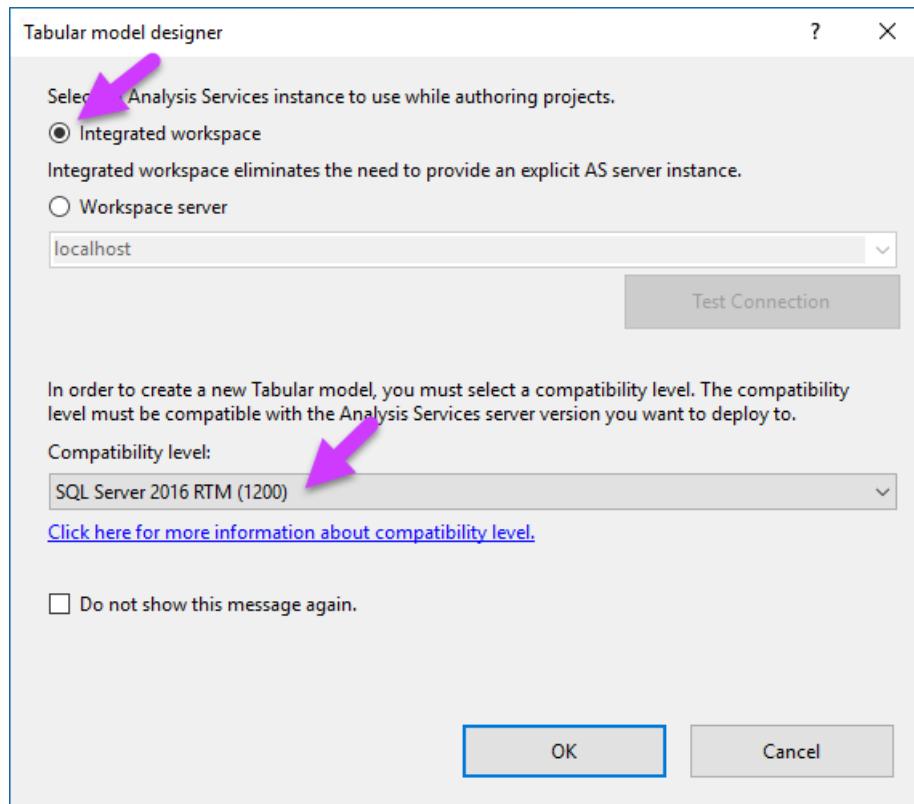

1. In SSDT, on the **File** menu, click **New > Project**.
2. In the **New Project** dialog box, expand **Installed > Business Intelligence > Analysis Services**, and then click **Analysis Services Tabular Project**.
3. In **Name**, type **AW Internet Sales**, and then specify a location for the project files.

By default, **Solution Name** will be the same as the project name; however, you can type a different solution name.

4. Click **OK**.
5. In the **Tabular model designer** dialog box, select **Integrated workspace**.

The workspace will host a tabular model database with the same name as the project during model authoring. Integrated workspace means SSDT will use a built-in instance, eliminating the need to install a separate Analysis Services server instance just for model authoring. To learn more, see [Workspace Database](#).

6. In **Compatibility level**, verify **SQL Server 2016 (1200)** is selected, and then click **OK**.

If you don't see SQL Server 2016 RTM (1200) in the Compatibility level listbox, you're not using the latest version of SQL Server Data Tools. To get the latest version, see [Install SQL Server Data tools](#).

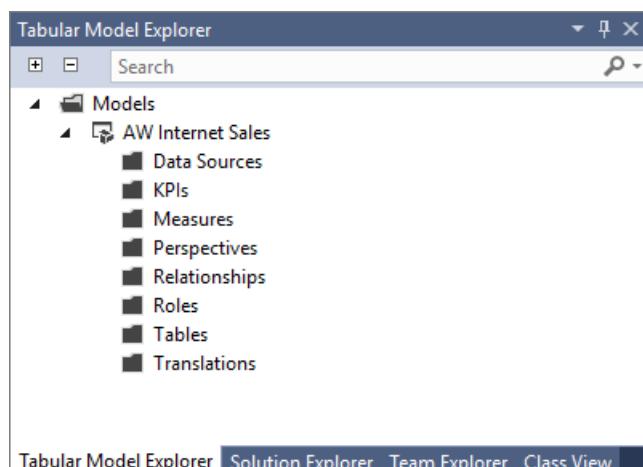

If you're using the latest version of SSDT, you can also choose SQL Server 2017 (1400). However, to complete lesson 13: Deploy, you'll need a SQL Server 2017 or Azure server to deploy to.

Selecting an earlier compatibility level is only recommended if you intend on deploying your completed tabular model to a different Analysis Services instance running an earlier version of SQL Server. Integrated workspace is not supported for earlier compatibility levels. To learn more see, [Compatibility level](#).

Understanding the SSDT tabular model authoring environment

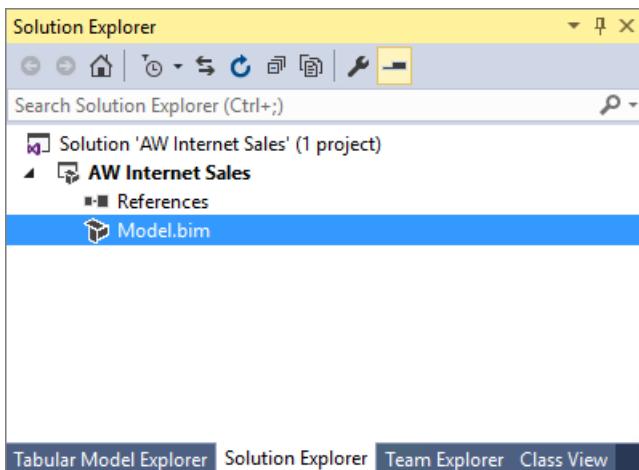

Now that you've created a new tabular model project, let's take a moment to explore the tabular model authoring environment in SSDT.

After your project is created, it opens in SSDT. On the right side, in **Tabular Model Explorer**, you'll see a tree view of the objects in your model. Since you haven't yet imported data, the folders will be empty. You can right-click an object folder to perform actions, similar to the menu bar. As you step through this tutorial, you'll use the Tabular Model Explorer to navigate different objects in your model project.

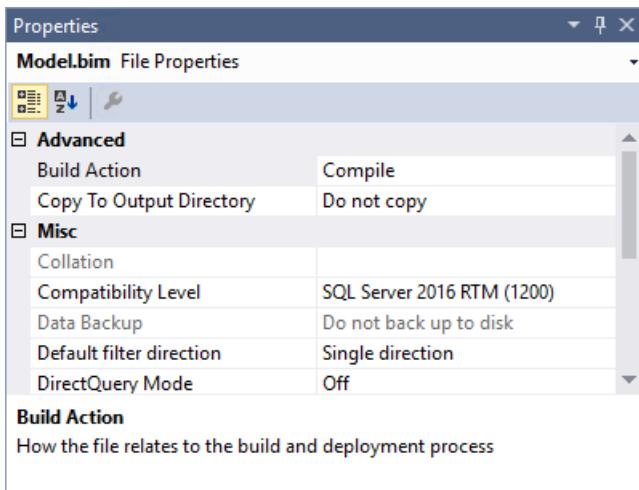

Click the **Solution Explorer** tab. Here, you'll see your **Model.bim** file. If you don't see the designer window to the

left (the empty window with the Model.bim tab), in **Solution Explorer**, under **AW Internet Sales Project**, double-click the **Model.bim** file. The Model.bim file contains all of the metadata for your model project.

Let's look at the model properties. Click **Model.bim**. In the **Properties** window, you'll see the [model properties](#), most important of which is the **DirectQuery Mode** property. This property specifies whether or not the model is deployed in In-Memory mode (Off) or DirectQuery mode (On). For this tutorial, you will author and deploy your model in In-Memory mode.

When you create a new model, certain model properties are set automatically according to the Data Modeling settings that can be specified in the **Tools > Options** dialog box. Data Backup, Workspace Retention, and Workspace Server properties specify how and where the workspace database (your model authoring database) is backed up, retained in-memory, and built. You can change these settings later if necessary, but for now, just leave these properties as they are.

In **Solution Explorer**, right-click **AW Internet Sales** (project), and then click **Properties**. The **AW Internet Sales Property Pages** dialog box appears. These are the advanced [project properties](#). You will set some of these properties later when you are ready to deploy your model.

When you installed SSDT, several new menu items were added to the Visual Studio environment. Let's look at those specific to authoring tabular models. Click on the **Model** menu. From here, you can launch the Table Import Wizard, view and edit existing connections, refresh workspace data, browse your model in Excel with the Analyze in Excel feature, create perspectives and roles, select the model view, and set calculation options.

Click on the **Table** menu. Here, you can create and manage relationships between tables, create and manage, specify date table settings, create partitions, and edit table properties.

Click on the **Column** menu. Here, you can add and delete columns in a table, freeze columns, and specify sort order. You can also use the AutoSum feature to create a standard aggregation measure for a selected column. Other toolbar buttons provide quick access to frequently used features and commands.

Explore some of the dialogs and locations for various features specific to authoring tabular models. While some items will not yet be active, you can get a good idea of the tabular model authoring environment.

Additional resources

To learn more about the different types of tabular model projects, see [Tabular Model Projects](#). To learn more about the tabular model authoring environment, see [Tabular Model Designer](#).

What's next?

Go to the next lesson: [Lesson 2: Add data](#).

Lesson 2: Add Data

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services (2016 and later) ✓ Azure Analysis Services ✗ Power BI Premium

In this lesson, you'll use the Table Import Wizard in SSDT to connect to the AdventureWorksDW SQL sample database, select data, preview and filter the data, and then import the data into your model workspace.

By using the Table Import Wizard, you can import data from a variety of relational sources: Access, SQL, Oracle, Sybase, Informix, DB2, Teradata, and more. The steps for importing data from each of these relational sources are very similar to what is described below. Data can also be selected using a stored procedure. To learn more about importing data and the different types of data sources you can import from, see [Data Sources](#).

Estimated time to complete this lesson: **20 minutes**

Prerequisites

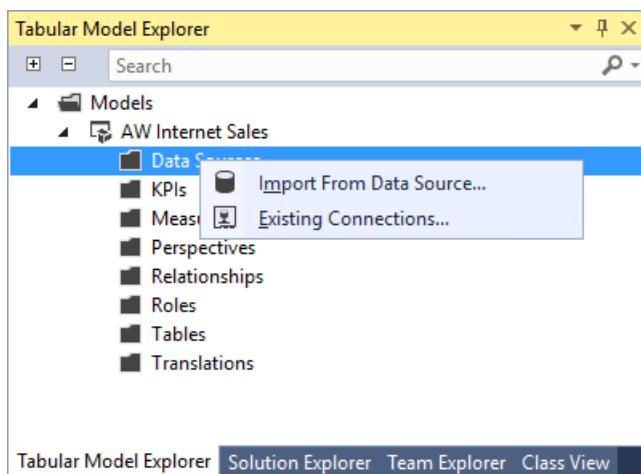

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 1: Create a New Tabular Model Project](#).

Create a connection

To create a connection to the AdventureWorksDW2014 database

1. In Tabular Model Explorer, right-click **Data Sources** > **Import from Data Source**.

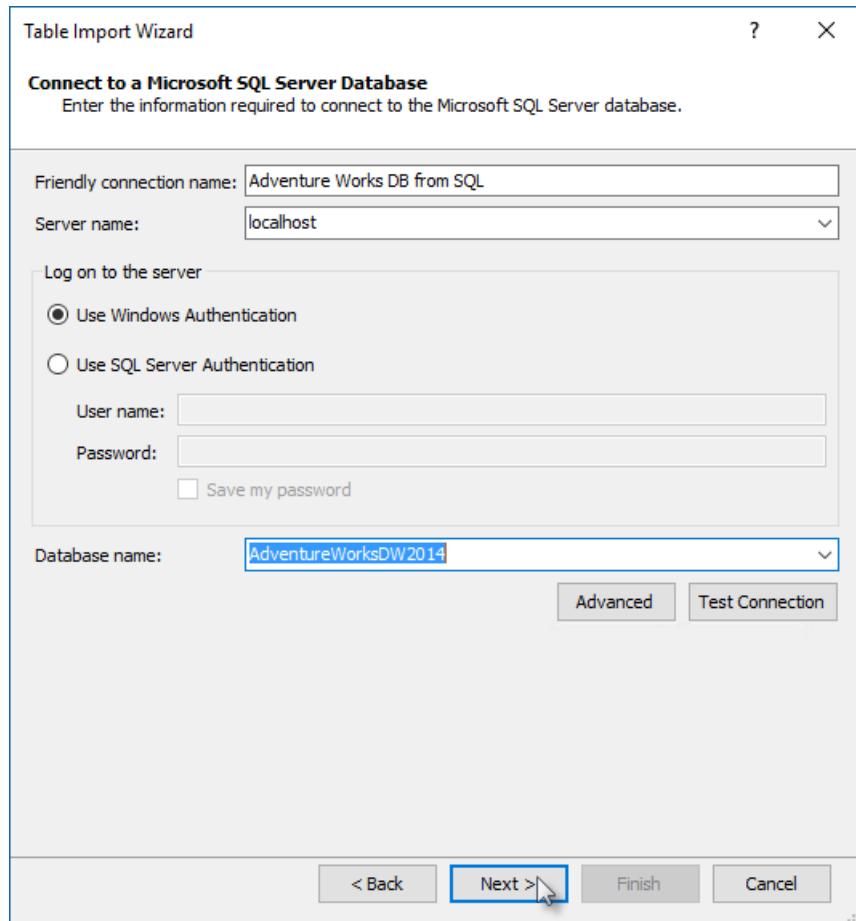

This launches the Table Import Wizard, which guides you through setting up a connection to a data source. If you don't see Tabular Model Explorer, double click **Model.bim** in **Solution Explorer** to open the model in the designer.

Note: If you're creating your model at the 1400 compatibility level, you'll see the new Get Data experience instead of the Table Import Wizard. The dialogs will appear a little different from the steps below, but you'll still be able to follow along.

2. In the Table Import Wizard, under **Relational Databases**, click **Microsoft SQL Server** > **Next**.
3. In the **Connect to a Microsoft SQL Server Database** page, in **Friendly Connection Name**, type **Adventure Works DB from SQL**.
4. In **Server name**, type the name of the server where you installed the AdventureWorksDW database.

5. In the **Database name** field, select **AdventureWorksDW**, and then click **Next**.

6. In the **Impersonation Information** page, you need to specify the credentials Analysis Services will use to connect to the data source when importing and processing data. Verify **Specific Windows user name and password** is selected, and then in **User Name** and **Password**, enter your Windows logon credentials, and then click **Next**.

NOTE

Using a Windows user account and password provides the most secure method of connecting to a data source. For more information, see [Impersonation](#).

7. In the **Choose How to Import the Data** page, verify **Select from a list of tables and views to choose the data to import** is selected. You want to select from a list of tables and views, so click **Next** to display a list of all the source tables in the source database.
8. In the **Select Tables and Views** page, select the check box for the following tables: **DimCustomer**, **DimDate**, **DimGeography**, **DimProduct**, **DimProductCategory**, **DimProductSubcategory**, and **FactInternetSales**.

DO NOT click **Finish**.

Filter the table data

The DimCustomer table that you're importing from the sample database contains a subset of the data from the original SQL Server Adventure Works database. You will filter out some more of the columns from the DimCustomer table that aren't necessary when imported into your model. When possible, you'll want to filter out data that won't be used in order to save in-memory space used by the model.

To filter the table data prior to importing

1. Select the row for the **DimCustomer** table, and then click **Preview & Filter**. The **Preview Selected Table** window opens with all the columns in the DimCustomer source table displayed.
2. Clear the checkbox at the top of the following columns: **SpanishEducation**, **FrenchEducation**, **SpanishOccupation**, **FrenchOccupation**.

Table Import Wizard

Preview Selected Table
Use the checkbox to select specific columns. To filter the data in a column, use the drop-down arrow for the column to select values that should be included.

Table Name: **DimCustomer**

| ChildrenAt... | <input checked="" type="checkbox"/> EnglishEdu... | <input type="checkbox"/> SpanishEdu... | <input type="checkbox"/> FrenchEdu... | <input type="checkbox"/> EnglishOccu... | <input checked="" type="checkbox"/> SpanishOccu... | <input checked="" type="checkbox"/> FrenchOcc... |
|---------------|---|--|---------------------------------------|---|--|--|
| 1 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 2 | 3 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 3 | 3 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 4 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 5 | 5 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 6 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 7 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 8 | 3 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 9 | 4 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 10 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 11 | 0 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 12 | 4 Bachelors | Licenciatura | Bac + 4 | Professional | Profesional | Cadre |
| 13 | 0 Bachelors | Licenciatura | Bac + 4 | Management | Gestión | Direction |
| 14 | 0 Bachelors | Licenciatura | Bac + 4 | Management | Gestión | Direction |
| 15 | 0 Bachelors | Licenciatura | Bac + 4 | Management | Gestión | Direction |

Clear Row Filters **OK** **Cancel**

Since the values for these columns are not relevant to Internet sales analysis, there is no need to import these columns. Eliminating unnecessary columns will make your model smaller and more efficient.

3. Verify that all other columns are checked, and then click **OK**.

Notice the words **Applied filters** are now displayed in the **Filter Details** column in the **DimCustomer** row; if you click on that link you'll see a text description of the filters you just applied.

Table Import Wizard

Select Tables and Views
Select the tables and views that you want to import data from.

Server: localhost
Database: AdventureWorksDW2014

Tables and Views:

| | Source Table | Schema | Friendly Name | Filter Details |
|-------------------------------------|-----------------------|--------|-----------------------|-----------------|
| <input type="checkbox"/> | DatabaseLog | dbo | | |
| <input type="checkbox"/> | DimAccount | dbo | | |
| <input type="checkbox"/> | DimCurrency | dbo | | |
| <input checked="" type="checkbox"/> | DimCustomer | dbo | DimCustomer | Applied filters |
| <input checked="" type="checkbox"/> | DimDate | dbo | DimDate | |
| <input type="checkbox"/> | DimDepartmentGroup | dbo | | |
| <input type="checkbox"/> | DimEmployee | dbo | | |
| <input checked="" type="checkbox"/> | DimGeography | dbo | DimGeography | |
| <input type="checkbox"/> | DimOrganization | dbo | | |
| <input checked="" type="checkbox"/> | DimProduct | dbo | DimProduct | |
| <input checked="" type="checkbox"/> | DimProductCategory | dbo | DimProductCategory | |
| <input checked="" type="checkbox"/> | DimProductSubcategory | dbo | DimProductSubcategory | |
| <input type="checkbox"/> | DimPromotion | dbo | | |
| <input type="checkbox"/> | DimReseller | dbo | | |

Select Related Tables **Preview & Filter**

< Back Next > Finish Cancel

4. Filter the remaining tables by clearing the checkboxes for the following columns in each table:

DimDate

| COLUMN |
|----------------------|
| DateKey |
| SpanishDayNameOfWeek |
| FrenchDayNameOfWeek |
| SpanishMonthName |
| FrenchMonthName |

DimGeography

| COLUMN |
|--------------------------|
| SpanishCountryRegionName |
| FrenchCountryRegionName |
| IpAddressLocator |

DimProduct

| COLUMN |
|----------------------------|
| SpanishProductName |
| FrenchProductName |
| FrenchDescription |
| ChineseDescription |
| ArabicDescription |
| HebrewDescription |
| ThaiDescription |
| GermanDescription |
| JapaneseDescription |
| TurkishDescription |

DimProductCategory

| COLUMN |
|-----------------------------------|
| SpanishProductCategoryName |
| FrenchProductCategoryName |

DimProductSubcategory

| COLUMN |
|--------------------------------------|
| SpanishProductSubcategoryName |
| FrenchProductSubcategoryName |

FactInternetSales

| COLUMN |
|---------------------|
| OrderDateKey |
| DueDateKey |
| ShipDateKey |

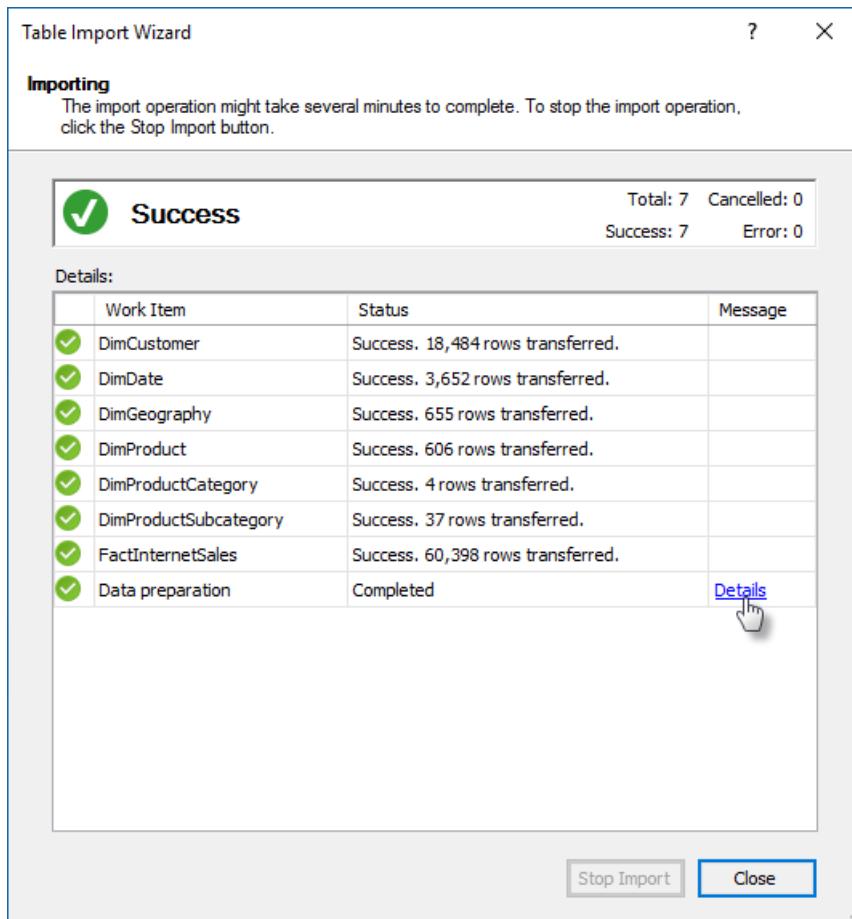

Import the selected tables and column data

Now that you've previewed and filtered out unnecessary data, you can import the rest of the data you do want. The wizard imports the table data along with any relationships between tables. New tables and columns are created in the model and data that you filtered out will not be imported.

To import the selected tables and column data

1. Review your selections. If everything looks okay, click **Finish**.

While importing the data, the wizard displays how many rows have been fetched. When all the data has been imported, a message indicating success is displayed.

**TIP**

To see the relationships that were automatically created between the imported tables, on the **Data preparation** row, click **Details**.

2. Click **Close**.

The wizard closes and the model designer now shows your imported tables.

Save your model project

It's important to frequently save your model project.

To save the model project

- Click **File > Save All**.

What's next?

Go to the next lesson: [Lesson 3: Mark as Date Table](#).

Lesson 3: Mark as Date Table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In Lesson 2: Add Data, you imported a dimension table named DimDate. While in your model this table is named DimDate, it can also be known as a *Date table*, in that it contains date and time data.

Whenever you use DAX time-intelligence functions in calculations, as you'll do when you create measures a little later, you must specify date table properties, which include a *Date table* and a unique identifier *Date column* in that table.

In this lesson, you'll mark the DimDate table as the *Date table* and the Date column (in the Date table) as the *Date column* (unique identifier).

Before we mark the date table and date column, we need to do a little housekeeping to make our model easier to understand. You'll notice in the DimDate table a column named **FullDateAlternateKey**. It contains one row for every day in each calendar year included in the table. We'll be using this column a lot in measure formulas and in reports. But, FullDateAlternateKey is not really a good identifier for this column. We'll rename it to **Date**, making it easier to identify and include in formulas. Whenever possible, it's a good idea to rename objects like tables and columns to make them easier to identify in client reporting applications like Power BI and Excel.

Estimated time to complete this lesson: **3 minutes**

Prerequisites

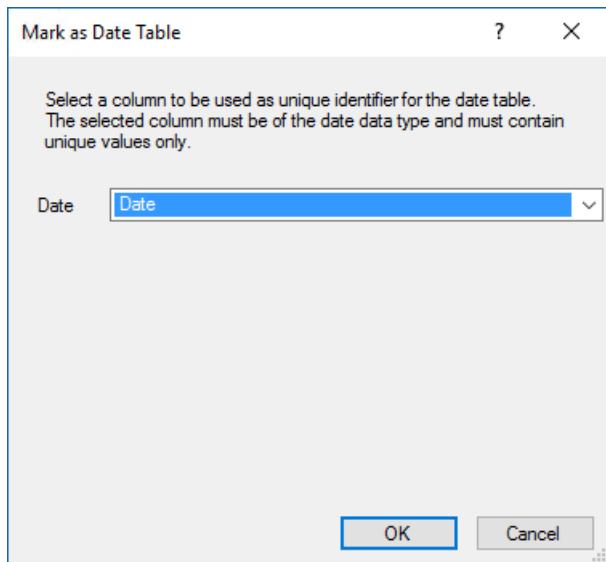

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 2: Add data](#).

To rename the **FullDateAlternateKey** column

1. In the model designer, click the **DimDate** table.
2. Double click the header for the **FullDateAlternateKey** column, and then rename it to **Date**.

To set Mark as Date Table

1. Select the **Date** column, and then in the **Properties** window, under **Data Type**, make sure **Date** is selected.
2. Click the **Table** menu, then click **Date**, and then click **Mark as Date Table**.
3. In the **Mark as Date Table** dialog box, in the **Date** listbox, select the **Date** column as the unique identifier. It will usually be selected by default. Click **OK**.

What's next?

Go to the next lesson: [Lesson 4: Create Relationships.](#)

Lesson 4: Create Relationships

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will verify the relationships that were created automatically when you imported data and add new relationships between different tables. A relationship is a connection between two tables that establishes how the data in those tables should be correlated. For example, the DimProduct table and the DimProductSubcategory table have a relationship based on the fact that each product belongs to a subcategory. To learn more, see [Relationships](#).

Estimated time to complete this lesson: **10 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 3: Mark as Date Table](#).

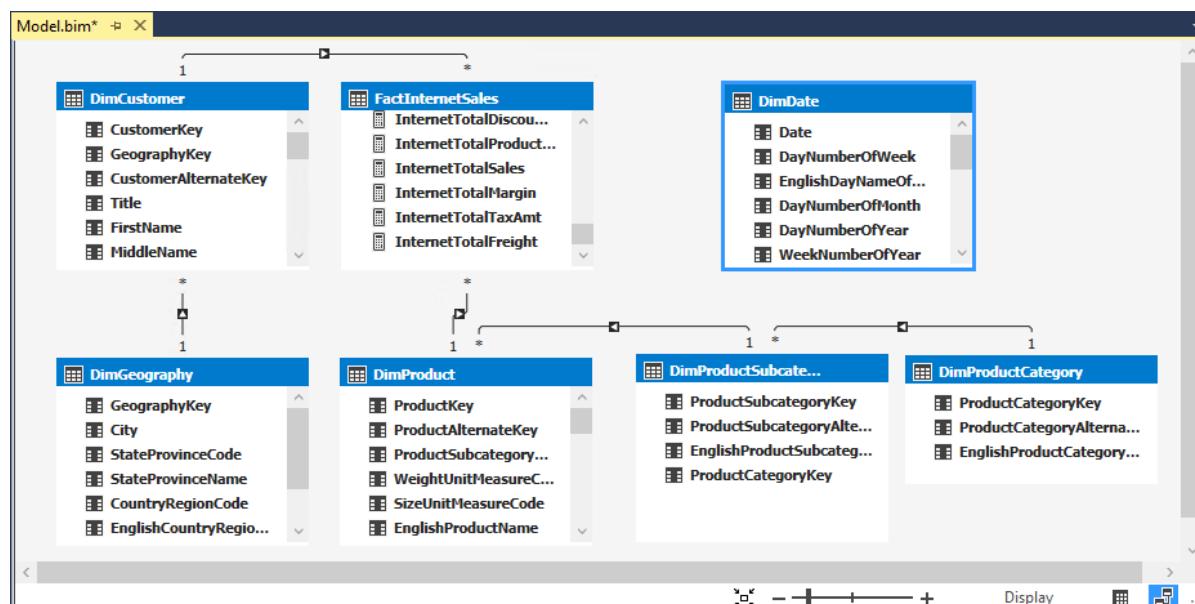

Review existing relationships and add new relationships

When you imported data by using the Table Import Wizard, you got seven tables from the AdventureWorksDW database. Generally, when you import data from a relational source, existing relationships are automatically imported together with the data. However, before you proceed with authoring your model you should verify those relationships between tables were created properly. For this tutorial, you will also add three new relationships.

To review existing relationships

1. Click the **Model** menu > **Model View** > **Diagram View**.

The model designer now appears in Diagram View, a graphical format displaying all of the tables you imported with lines between them. The lines between tables indicate the relationships that were automatically created when you imported the data.

Use the minimap controls in the lower-right corner of the model designer to adjust the view to include as many of the tables as possible. You can also click, and drag tables to different locations, bringing tables

closer together, or putting them in a particular order. Moving tables does not affect the relationships already between the tables. To view all of the columns in a particular table, click, and drag on a table edge to expand or make it smaller.

2. Click the solid line between the **DimCustomer** table and the **DimGeography** table. The solid line between these two tables show this relationship is active, that is, it is used by default when calculating DAX formulas.

Notice the **GeographyKey** column in the **DimCustomer** table and the **GeographyKey** column in the **DimGeography** table now both each appear within a box. This show these are the columns used in the relationship. The relationship's properties now also appear in the **Properties** window.

TIP

In addition to using the model designer in diagram view, you can also use the Manage Relationships dialog box to show the relationships between all tables in a table format. Right-click **Relationships** in Tabular Model Explorer, and then click **Manage Relationships**. The Manage Relationships dialog box show the relationships that were automatically created when you imported data.

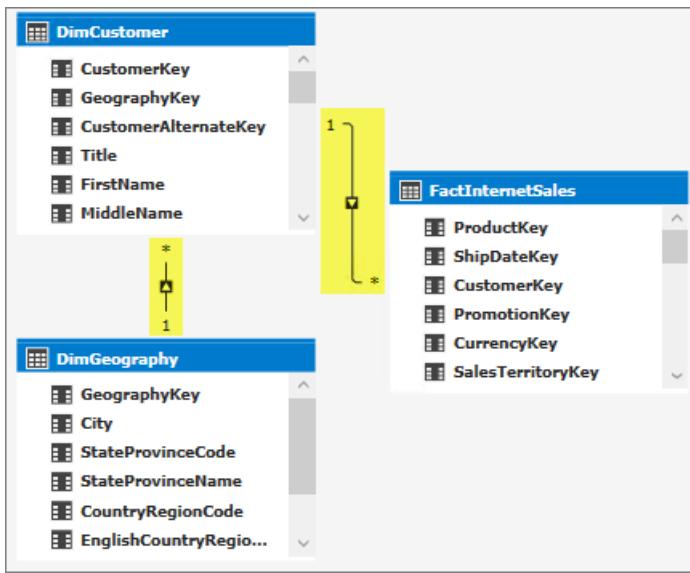

3. Use the model designer in diagram view, or the Manage Relationships dialog box, to verify the following relationships were created when each of the tables were imported from the AdventureWorksDW database:

| ACTIVE | TABLE | RELATED LOOKUP TABLE |
|--------|---|--|
| Yes | DimCustomer [GeographyKey] | DimGeography [GeographyKey] |
| Yes | DimProduct
[ProductSubcategoryKey] | DimProductSubcategory
[ProductSubcategoryKey] |
| Yes | DimProductSubcategory
[ProductCategoryKey] | DimProductCategory
[ProductCategoryKey] |
| Yes | FactInternetSales [CustomerKey] | DimCustomer [CustomerKey] |
| Yes | FactInternetSales [ProductKey] | DimProduct [ProductKey] |

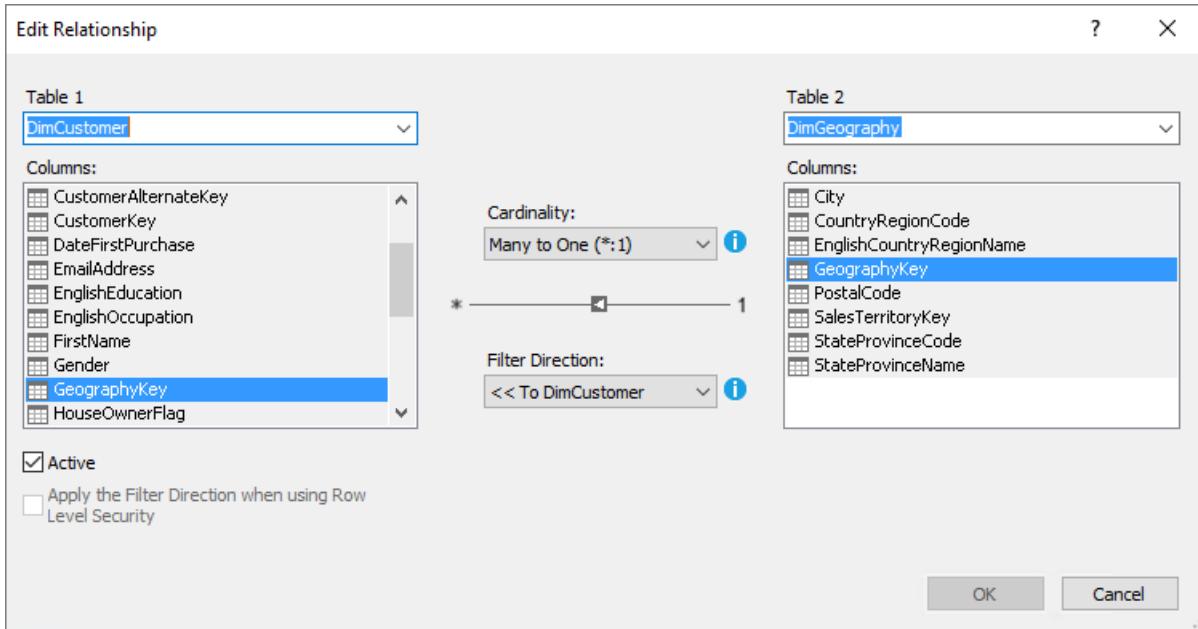

If any of the relationships in the table above are missing, verify that your model includes the following tables: DimCustomer, DimDate, DimGeography, DimProduct, DimProductCategory, DimProductSubcategory, and FactInternetSales. If tables from the same data source connection are imported at separate times, any relationships between those tables will not be created and must be created manually.

Take a closer look

In Diagram View, you'll notice an arrow, an asterisk, and a number on the lines that show the relationship between tables.

The arrow shows the filter direction, the asterisk shows this table is the many side in the relationship's cardinality, and the 1 shows this table is the one side of the relationship. If you need to edit a relationship; for example, change the relationship's filter direction or cardinality, double-click the relationship line in Diagram View to open the Edit Relationship dialog.

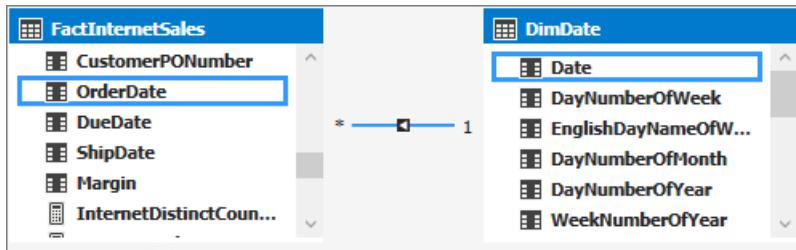

Most likely, you will never need to edit a relationship. These features are meant for advanced data modeling and are outside the scope of this tutorial. To learn more, see [Bi-directional cross filters for tabular models in SQL Server 2016 Analysis Services](#).

In some cases, you may need to create additional relationships between tables in your model to support certain business logic. For this tutorial, you need to create three additional relationships between the FactInternetSales table and the DimDate table.

To add new relationships between tables

1. In the model designer, in the **FactInternetSales** table, click, and hold on the **OrderDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

A solid line appears showing you have created an active relationship between the **OrderDate** column in the **Internet Sales** table and the **Date** column in the **Date** table.

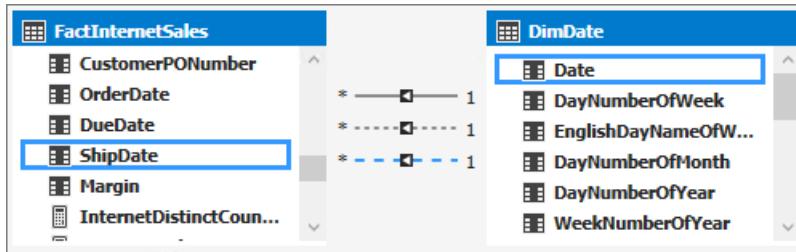

NOTE

When creating relationships, the cardinality and filter direction between the primary table and the related lookup table is automatically selected.

2. In the **FactInternetSales** table, click, and hold on the **DueDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

A dotted line appears showing you have created an inactive relationship between the **DueDate** column in the **FactInternetSales** table and the **Date** column in the **DimDate** table. You can have multiple relationships between tables, but only one relationship can be active at a time.

3. Finally, create one more relationship; in the **FactInternetSales** table, click, and hold on the **ShipDate** column, then drag the cursor to the **Date** column in the **DimDate** table, and then release.

What's next?

Go to the next lesson: [Lesson 5: Create Calculated Columns.](#)

Lesson 5: Create Calculated Columns

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create new data in your model by adding calculated columns. A calculated column is based on data that already exists in the model. To learn more, see [Calculated Columns](#).

You will create five new calculated columns in three different tables. The steps are slightly different for each task. This is to show you there are several ways to create new columns, rename them, and place them in various locations in a table.

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 4: Create Relationships](#).

Create calculated columns

Create a MonthCalendar calculated column in the DimDate table

1. Click the **Model** menu > **Model View** > **Data View**.

Calculated columns can only be created by using the model designer in Data View.

2. In the model designer, click the **DimDate** table (tab).
3. Right-click the **CalendarQuarter** column header, and then click **Insert Column**.

A new column named **Calculated Column 1** is inserted to the left of the **Calendar Quarter** column.

4. In the formula bar above the table, type the following formula. AutoComplete helps you type the fully qualified names of columns and tables, and lists the functions that are available.

```
=RIGHT(" " & FORMAT([MonthNumberOfYear],"#0"), 2) & " - " & [EnglishMonthName]
```

Values are then populated for all the rows in the calculated column. If you scroll down through the table, you will see that rows can have different values for this column, based on the data that is in each row.

5. Rename this column to **MonthCalendar**.

The screenshot shows the Microsoft Analysis Services Model Designer interface. The title bar says 'Model.bim'. The main area displays the 'DimDate' table. A new column, 'MonthCalendar', has been added to the left of the 'CalendarQuarter' column. The formula for this column is visible in the formula bar: '=RIGHT(" " & FORMAT([MonthNumberOfYear],"#0"), 2) & " - " & [EnglishMonthName]'. The table data shows rows for July and August of 2010, with the 'MonthCalendar' column providing a descriptive name like '7 - July' or '8 - August'.

| Name | MonthNumberOfYear | MonthCalendar | CalendarQuarter | CalendarYear | CalendarSemester | FiscalQua |
|------|-------------------|---------------|-----------------|--------------|------------------|-----------|
| 29 | 7 | 7 - July | 3 | 2010 | | 2 |
| 30 | 7 | 7 - July | 3 | 2010 | | 2 |
| 31 | 7 | 7 - July | 3 | 2010 | | 2 |
| 32 | 8 | 8 - August | 3 | 2010 | | 2 |
| 33 | 8 | 8 - August | 3 | 2010 | | 2 |
| 34 | 8 | 8 - August | 3 | 2010 | | 2 |

The MonthCalendar calculated column provides a sortable name for Month.

Create a DayOfWeek calculated column in the DimDate table

1. With the **DimDate** table still active, click on the **Column** menu, and then click **Add Column**.

2. In the formula bar, type the following formula:

```
=RIGHT(" " & FORMAT([DayNumberOfWeek],"#0"), 2) & " - " & [EnglishDayNameOfWeek]
```

When you've finished building the formula, press ENTER. The new column is added to the far right of the table.

3. Rename the column to **DayOfWeek**.

4. Click on the column heading, and then drag the column between the **EnglishDayNameOfWeek** column and the **DayNumberOfMonth** column.

TIP

Moving columns in your table makes it easier to navigate.

The DayOfWeek calculated column provides a sortable name for the day of week.

Create a ProductSubcategoryName calculated column in the DimProduct table

1. In the **DimProduct** table, scroll to the far right of the table. Notice the right-most column is named **Add Column** (italicized), click the column heading.

2. In the formula bar, type the following formula:

```
=RELATED('DimProductSubcategory'[EnglishProductSubcategoryName])
```

3. Rename the column to **ProductSubcategoryName**.

The ProductSubcategoryName calculated column is used to create a hierarchy in the DimProduct table which includes data from the EnglishProductSubcategoryName column in the DimProductSubcategory table.

Hierarchies cannot span more than one table. You will create hierarchies later in Lesson 9.

Create a ProductCategoryName calculated column in the DimProduct table

1. With the **DimProduct** table still active, click the **Column** menu, and then click **Add Column**.

2. In the formula bar, type the following formula:

```
=RELATED('DimProductCategory'[EnglishProductCategoryName])
```

3. Rename the column to **ProductCategoryName**.

The ProductCategoryName calculated column is used to create a hierarchy in the DimProduct table which includes data from the EnglishProductCategoryName column in the DimProductCategory table. Hierarchies cannot span more than one table.

Create a Margin calculated column in the FactInternetSales table

1. In the model designer, select the **FactInternetSales** table.

2. Add a new column.

3. In the formula bar, type the following formula:

```
=[SalesAmount]-[TotalProductCost]
```

4. Rename the column to **Margin**.
5. Drag the column between the **SalesAmount** column and the **TaxAmt** column.

| | ProductCost | SalesAmount | Margin | TaxAmt | Freight | CarrierTrackingNumber | CustomerPONum |
|-------|-------------|-------------|---------|--------|---------|-----------------------|---------------|
| 25553 | \$41.57 | \$53.99 | \$12.42 | \$4.32 | \$1.35 | | |
| 25554 | \$2.97 | \$7.95 | \$4.98 | \$0.64 | \$0.20 | | |
| 25555 | \$20.57 | \$54.99 | \$34.42 | \$4.40 | \$1.37 | | |
| 25556 | \$9.16 | \$24.49 | \$15.33 | \$1.96 | \$0.61 | | |
| 25557 | \$44.88 | \$120.00 | \$75.12 | \$9.60 | \$3.00 | | |
| 25558 | \$1.87 | \$4.99 | \$3.12 | \$0.40 | \$0.12 | | |
| 25559 | \$1.49 | \$3.99 | \$2.50 | \$0.32 | \$0.10 | | |

The Margin calculated column is used to analyze profit margins for each sale.

What's next?

Go to the next lesson: [Lesson 6: Create Measures](#).

Lesson 6: Create Measures

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create measures to be included in your model. Similar to the calculated columns you created in the previous lesson, a measure is a calculation created by using a DAX formula. However, unlike calculated columns, measures are evaluated based on a user selected *filter*; for example, a particular column or slicer added to the Row Labels field in a PivotTable. A value for each cell in the filter is then calculated by the applied measure. Measures are powerful, flexible calculations that you will want to include in almost all tabular models to perform dynamic calculations on numerical data. To learn more, see [Measures](#).

To create measures, you will use the *Measure Grid*. By default, each table has an empty measure grid; however, you typically will not create measures for every table. The measure grid appears below a table in the model designer when in Data View. To hide or show the measure grid for a table, click the **Table** menu, and then click **Show Measure Grid**.

You can create a measure by clicking on an empty cell in the measure grid, and then typing a DAX formula in the formula bar. When you click ENTER to complete the formula, the measure will then appear in the cell. You can also create measures using a standard aggregation function by clicking on a column, and then clicking on the AutoSum button (Σ) on the toolbar. Measures created using the AutoSum feature will appear in the measure grid cell directly beneath the column, but can be moved.

In this lesson, you will create measures by both entering a DAX formula in the formula bar and by using the AutoSum feature.

Estimated time to complete this lesson: **30 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 5: Create Calculated Columns](#).

Create measures

To create a DaysCurrentQuarterToDate measure in the DimDate table

1. In the model designer, click the **DimDate** table.
2. In the measure grid, click the top-left empty cell.
3. In the formula bar, type the following formula:

```
DaysCurrentQuarterToDate:=COUNTRROWS( DATESQTD( 'DimDate'[Date]))
```

Notice the top-left cell now contains a measure name, **DaysCurrentQuarterToDate**, followed by the result, **92**.

Model.bim* [Date] DaysCurrentQuarterToDate:=COUNTROWS(DATESQTD('DimDate'[Date]))

| Date | Day... | EnglishDayNameOfWeek | DayOfWeek | DayNumberOfMon |
|------------------------------|--------|----------------------|--------------|----------------|
| 7/1/2010 12:00:00 AM | 5 | Thursday | 5 - Thursday | |
| 7/2/2010 12:00:00 AM | 6 | Friday | 6 - Friday | |
| 7/3/2010 12:00:00 AM | 7 | Saturday | 7 - Saturday | |
| 7/4/2010 12:00:00 AM | 1 | Sunday | 1 - Sunday | |
| 7/5/2010 12:00:00 AM | 2 | Monday | 2 - Monday | |
| 7/6/2010 12:00:00 AM | 3 | Tuesday | 3 - Tuesday | |
| DaysCurrentQuarterToDate: 92 | | | | |

Unlike calculated columns, with measure formulas you can type the measure name, followed by a comma, followed by the formula expression.

To create a DaysInCurrentQuarter measure in the DimDate table

- With the **DimDate** table still active in the model designer, in the measure grid, click the empty cell below the measure you just created.
- In the formula bar, type the following formula:

```
DaysInCurrentQuarter:=COUNTROWS( DATESBETWEEN( 'DimDate'[Date], STARTOFQUARTER( LASTDATE('DimDate'[Date])), ENDOFQUARTER('DimDate'[Date])))
```

When creating a comparison ratio between one incomplete period and the previous period; the formula must take into account the proportion of the period that has elapsed, and compare it to the same proportion in the previous period. In this case, [DaysCurrentQuarterToDate]/[DaysInCurrentQuarter] gives the proportion elapsed in the current period.

To create an InternetDistinctCountSalesOrder measure in the FactInternetSales table

- Click the **FactInternetSales** table.
- Click on the **SalesOrderNumber** column heading.
- On the toolbar, click the down-arrow next to the AutoSum (Σ) button, and then select **DistinctCount**.

The AutoSum feature automatically creates a measure for the selected column using the DistinctCount standard aggregation formula.

Model.bim* [SalesOrderNumb... Distinct Count SalesOrderNumber:=DISTINCTCOUNT([SalesOrderNumber])

| SalesOrderNumb... | SalesTerritoryKey | SalesOrderNumber | SalesOrderLineNumber | RevisionNumber | Orde... |
|--|-------------------|------------------|----------------------|----------------|---------|
| 1 | 100 | 4 SO51900 | | 1 | 1 |
| 2 | 100 | 4 SO51948 | | 1 | 1 |
| 3 | 100 | 4 SO52043 | | 1 | 1 |
| 4 | 100 | 4 SO52045 | | 1 | 1 |
| 5 | 100 | 4 SO52094 | | 1 | 1 |
| 6 | 100 | 4 SO52175 | | 1 | 1 |
| Distinct Count SalesOrderNumber: 27659 | | | | | |

- In the measure grid, click the new measure, and then in the **Properties** window, in **Measure Name**, rename the measure to **InternetDistinctCountSalesOrder**.

To create additional measures in the FactInternetSales table

- By using the AutoSum feature, create and name the following measures:

| MEASURE NAME | COLUMN | AUTOSUM (Σ) | FORMULA |
|-------------------------|----------------------|----------------------|-------------------------------------|
| InternetOrderLinesCount | SalesOrderLineNumber | Count | =COUNTA([SalesOrderLine
Number]) |

| MEASURE NAME | COLUMN | AUTOSUM (Σ) | FORMULA |
|-----------------------------|------------------|----------------------|--------------------------|
| InternetTotalUnits | OrderQuantity | Sum | =SUM([OrderQuantity]) |
| InternetTotalDiscountAmount | DiscountAmount | Sum | =SUM([DiscountAmount]) |
| InternetTotalProductCost | TotalProductCost | Sum | =SUM([TotalProductCost]) |
| InternetTotalSales | SalesAmount | Sum | =SUM([SalesAmount]) |
| InternetTotalMargin | Margin | Sum | =SUM([Margin]) |
| InternetTotalTaxAmt | TaxAmt | Sum | =SUM([TaxAmt]) |
| InternetTotalFreight | Freight | Sum | =SUM([Freight]) |

2. By clicking on an empty cell in the measure grid, and by using the formula bar, create and name the following measures in order:

```
InternetPreviousQuarterMargin:=CALCULATE([InternetTotalMargin],PREVIOUSQUARTER('DimDate'[Date]))
```

```
InternetCurrentQuarterMargin:=TOTALQTD([InternetTotalMargin],'DimDate'[Date])
```

```
InternetPreviousQuarterMarginProportionToQTD:=[InternetPreviousQuarterMargin]*  
([DaysCurrentQuarterToDate]/[DaysInCurrentQuarter])
```

```
InternetPreviousQuarterSales:=CALCULATE([InternetTotalSales],PREVIOUSQUARTER('DimDate'[Date]))
```

```
InternetCurrentQuarterSales:=TOTALQTD([InternetTotalSales],'DimDate'[Date])
```

```
InternetPreviousQuarterSalesProportionToQTD:=[InternetPreviousQuarterSales]*  
([DaysCurrentQuarterToDate]/[DaysInCurrentQuarter])
```

Measures created for the FactInternetSales table can be used to analyze critical financial data such as sales, costs, and profit margin for items defined by the user selected filter.

What's next?

Go to the next lesson: [Lesson 7: Create Key Performance Indicators.](#)

Lesson 7: Create Key Performance Indicators

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create Key Performance Indicators (KPIs). KPIs are used to gauge performance of a value, defined by a *Base* measure, against a *Target* value, also defined by a measure or by an absolute value. In reporting client applications, KPIs can provide business professionals a quick and easy way to understand a summary of business success or to identify trends. To learn more, see [KPIs](#).

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 6: Create Measures](#).

Create Key Performance Indicators

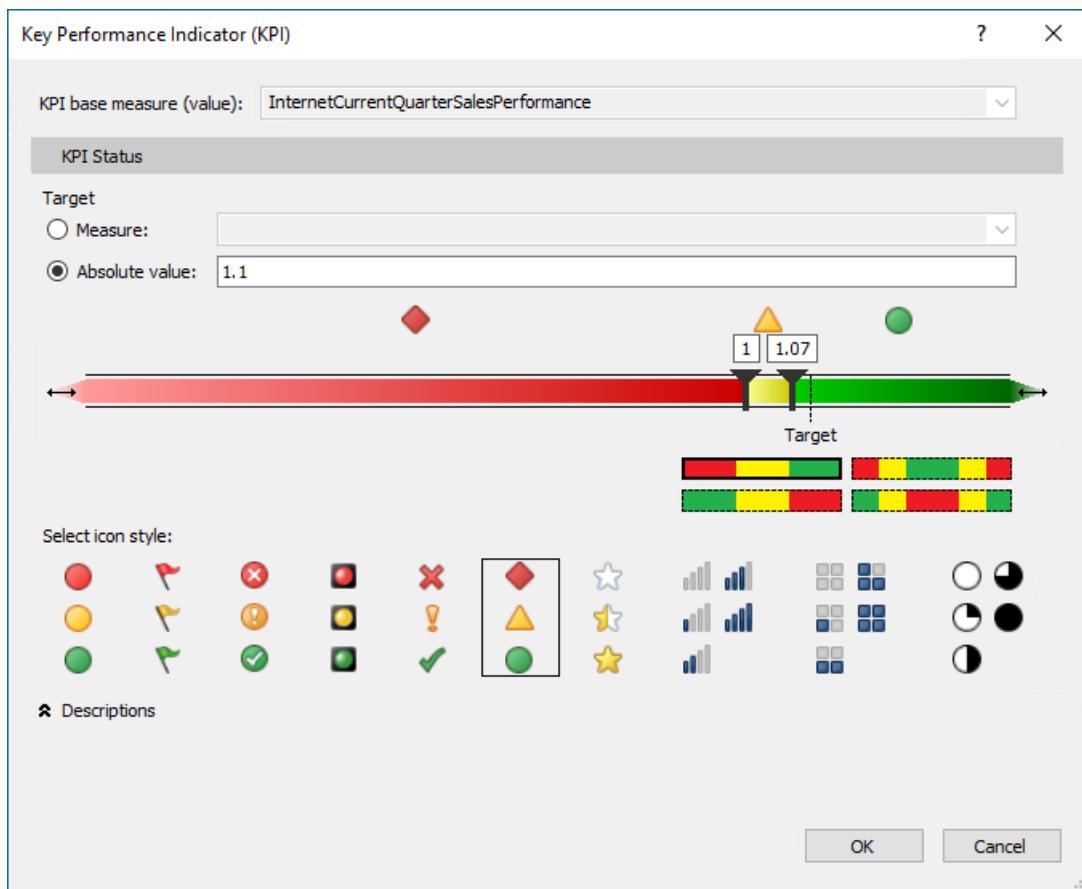

To create an InternetCurrentQuarterSalesPerformance KPI

1. In the model designer, click the **FactInternetSales** table (tab).
2. In the measure grid, click an empty cell.
3. In the formula bar, above the table, type the following formula:

```
InternetCurrentQuarterSalesPerformance  
:=IFERROR([InternetCurrentQuarterSales]/[InternetPreviousQuarterSalesProportionToQTD],BLANK())
```

This measure will serve as the Base measure for the KPI.

4. Right-click **InternetCurrentQuarterSalesPerformance** > **Create KPI**.
5. In the Key Performance Indicator (KPI) dialog box, in **Target** select **Absolute Value**, and then type **1.1**.
6. In the left (low) slider field, type **1**, and then in the right (high) slider field, type **1.07**.
7. In **Select Icon Style**, select the diamond (red), triangle (yellow), circle (green) icon type.

TIP

Notice the expandable **Descriptions** label below the available icon styles. Use this to enter descriptions for the various KPI elements to make them more identifiable in client applications.

- Click **OK** to complete the KPI.

In the measure grid, notice the icon next to the **InternetCurrentQuarterSalesPerformance** measure. This icon indicates that this measure serves as a Base value for a KPI.

To create an **InternetCurrentQuarterMarginPerformance** KPI

- In the measure grid for the **FactInternetSales** table, click an empty cell.
- In the formula bar, above the table, type the following formula:

```
InternetCurrentQuarterMarginPerformance :=IF([InternetPreviousQuarterMarginProportionToQTD]<>0,
([InternetCurrentQuarterMargin]-
[InternetPreviousQuarterMarginProportionToQTD])/[InternetPreviousQuarterMarginProportionToQTD],BLANK())
```

- Right-click **InternetCurrentQuarterMarginPerformance** > **Create KPI**.
- In the Key Performance Indicator (KPI) dialog box, in **Target** select **Absolute Value**, and then type **1.25**.
- In **Define Status Thresholds**, slide the left (low) slider field until the field displays **0.8**, and then slide the right (high) slider field, until the field displays **1.03**.
- In **Select Icon Style**, select the diamond (red), triangle (yellow), circle (green) icon type, and then click **OK**.

What's next?

Go to the next lesson: [Lesson 8: Create Perspectives](#).

Lesson 8: Create Perspectives

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create an Internet Sales perspective. A perspective defines a viewable subset of a model that provides focused, business-specific, or application-specific viewpoints. When a user connects to a model by using a perspective, they see only those model objects (tables, columns, measures, hierarchies, and KPIs) as fields defined in that perspective.

The Internet Sales perspective you create in this lesson will exclude the DimCustomer table object. When you create a perspective that excludes certain objects from view, that object still exists in the model; however, it is not visible in a reporting client field list. Calculated columns and measures either included in a perspective or not can still calculate from object data that is excluded.

The purpose of this lesson is to describe how to create perspectives and become familiar with the tabular model authoring tools. If you later expand this model to include additional tables, you can create additional perspectives to define different viewpoints of the model, for example, Inventory and Sales. To learn more, see [Perspectives](#).

Estimated time to complete this lesson: **5 minutes**

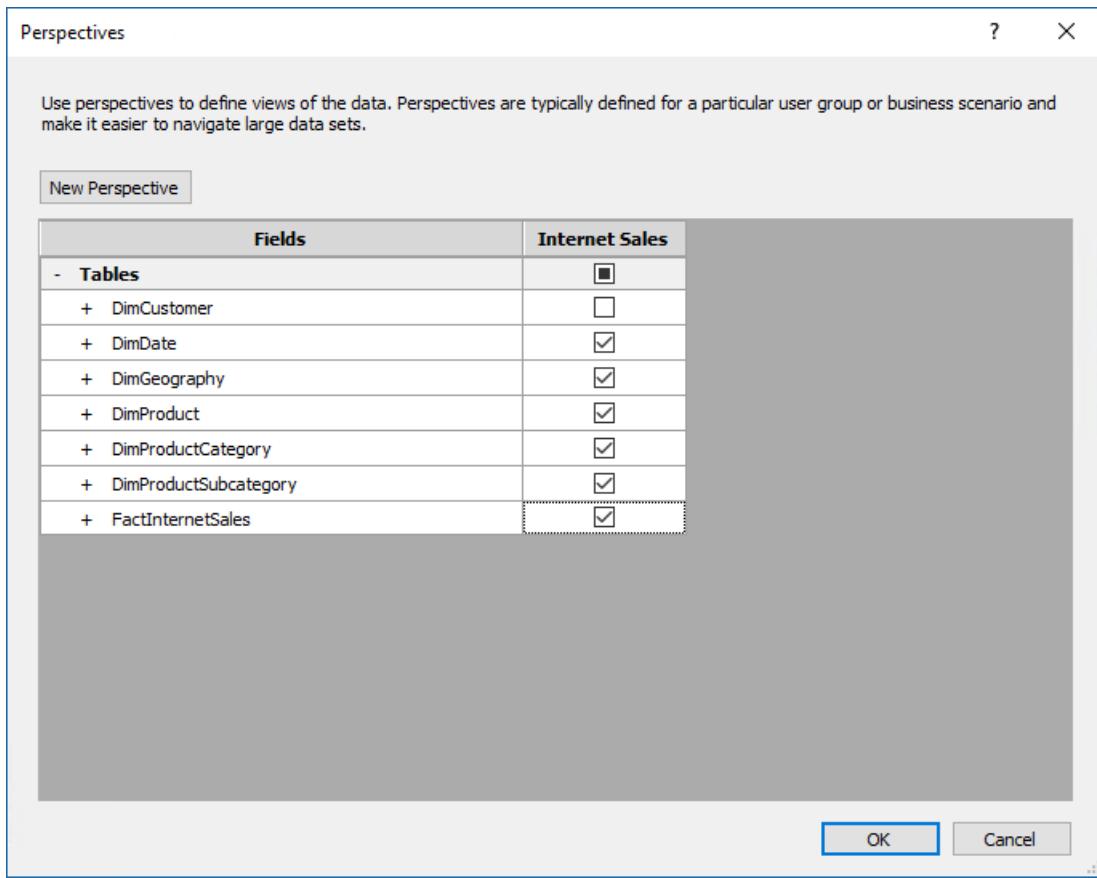

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 7: Create Key Performance Indicators](#).

Create perspectives

To create an Internet Sales perspective

1. Click the **Model** menu > **Perspectives** > **Create and Manage**.
2. In the **Perspectives** dialog box, click **New Perspective**.
3. Double-click the **New Perspective** column heading, and then rename **Internet Sales**.
4. Select the all of the tables *except DimCustomer*.

In a later lesson, you will use the Analyze in Excel feature to test this perspective. The Excel PivotTable Fields List will include each table except the DimCustomer table.

What's next?

Go to the next lesson: [Lesson 9: Create Hierarchies](#).

Lesson 9: Create Hierarchies

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create hierarchies. Hierarchies are groups of columns arranged in levels; for example, a Geography hierarchy might have sub-levels for Country, State, County, and City. Hierarchies can appear separate from other columns in a reporting client application field list, making them easier for client users to navigate and include in a report. To learn more, see [Hierarchies](#).

To create hierarchies, you'll use the model designer in *Diagram View*. Creating and managing hierarchies is not supported in *Data View*.

Estimated time to complete this lesson: **20 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 8: Create Perspectives](#).

Create hierarchies

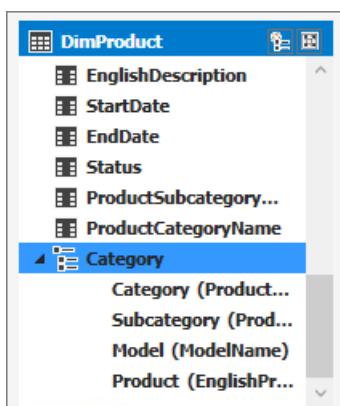

To create a Category hierarchy in the DimProduct table

1. In the model designer (diagram view), right-click the **DimProduct** table > **Create Hierarchy**. A new hierarchy appears at the bottom of the table window. Rename the hierarchy **Category**.
2. Click and drag the **ProductCategoryName** column to the new **Category** hierarchy.
3. In the **Category** hierarchy, right-click the **ProductCategoryName** > **Rename**, and then type **Category**.

NOTE

Renaming a column in a hierarchy does not rename that column in the table. A column in a hierarchy is just a representation of the column in the table.

4. Click and drag the **ProductSubcategoryName** column to the **Category** hierarchy. Rename it **Subcategory**.
5. Right-click the **ModelName** column > **Add to hierarchy**, and then select **Category**. Do the same for **EnglishProductName**. Rename these columns in the hierarchy **Model** and **Product**.

To create hierarchies in the DimDate table

1. In the **DimDate** table, create a new hierarchy named **Calendar**.
2. Add the following columns in-order:
 - CalendarYear
 - CalendarSemester
 - CalendarQuarter
 - MonthCalendar
 - DayNumberOfMonth
3. In the **DimDate** table, create a **Fiscal** hierarchy. Include the following columns:
 - FiscalYear
 - FiscalSemester
 - FiscalQuarter
 - MonthCalendar
 - DayNumberOfMonth
4. Finally, in the **DimDate** table, create a **ProductionCalendar** hierarchy. Include the following columns:
 - CalendarYear
 - WeekNumberOfYear
 - DayNumberOfWeek

What's next?

Go to the next lesson: [Lesson 10: Create Partitions](#).

Lesson 10: Create Partitions

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create partitions to divide the FactInternetSales table into smaller logical parts that can be processed (refreshed) independent of other partitions. By default, every table you include in your model has one partition which includes all of the table's columns and rows. For the FactInternetSales table, we want to divide the data by year; one partition for each of the table's five years. Each partition can then be processed independently. To learn more, see [Partitions](#).

Estimated time to complete this lesson: **15 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 9: Create Hierarchies](#).

Create partitions

To create partitions in the FactInternetSales table

1. In Tabular Model Explorer, expand **Tables**, right-click **FactInternetSales** > **Partitions**.
2. In the Partition Manager dialog box, click **Copy**.
3. In **Partition Name**, change the name to **FactInternetSales2010**.

TIP

Notice the column names in the Table Preview window display those columns included in the model table (checked) with the column names from the source. This is because the Table Preview window displays columns from the source table, not from the model table.

4. Select the **SQL** button just above the right side of the preview window to open the SQL Statement editor.

Because you want the partition to include only those rows within a certain period, you must include a WHERE clause. You can only create a WHERE clause by using a SQL Statement.

5. In the **SQL Statement** field, replace the existing statement by copying and pasting the following statement:

```

SELECT
[dbo].[FactInternetSales].[ProductKey],
[dbo].[FactInternetSales].[CustomerKey],
[dbo].[FactInternetSales].[PromotionKey],
[dbo].[FactInternetSales].[CurrencyKey],
[dbo].[FactInternetSales].[SalesTerritoryKey],
[dbo].[FactInternetSales].[SalesOrderNumber],
[dbo].[FactInternetSales].[SalesOrderLineNumber],
[dbo].[FactInternetSales].[RevisionNumber],
[dbo].[FactInternetSales].[OrderQuantity],
[dbo].[FactInternetSales].[UnitPrice],
[dbo].[FactInternetSales].[ExtendedAmount],
[dbo].[FactInternetSales].[UnitPriceDiscountPct],
[dbo].[FactInternetSales].[DiscountAmount],
[dbo].[FactInternetSales].[ProductStandardCost],
[dbo].[FactInternetSales].[TotalProductCost],
[dbo].[FactInternetSales].[SalesAmount],
[dbo].[FactInternetSales].[TaxAmt],
[dbo].[FactInternetSales].[Freight],
[dbo].[FactInternetSales].[CarrierTrackingNumber],
[dbo].[FactInternetSales].[CustomerPONumber],
[dbo].[FactInternetSales].[OrderDate],
[dbo].[FactInternetSales].[DueDate],
[dbo].[FactInternetSales].[ShipDate]
FROM [dbo].[FactInternetSales]
WHERE ((([OrderDate] >= N'2010-01-01 00:00:00') AND ([OrderDate] < N'2011-01-01 00:00:00')))
```

This statement specifies the partition should include all of the data in those rows where the OrderDate is for the 2010 calendar year as specified in the WHERE clause.

6. Click **Validate**.

To create a partition for the 2011 year

1. In the partitions list, click the **FactInternetSales2010** partition you just created, and then click **Copy**.
2. In **Partition Name**, type **FactInternetSales2011**.
3. In the SQL Statement, in-order for the partition to include only those rows for the 2011 year, replace the WHERE clause with the following:

```
WHERE (([OrderDate] >= N'2011-01-01 00:00:00') AND ([OrderDate] < N'2012-01-01 00:00:00'))
```

To create a partition for the 2012 year

- Follow the steps above, using the following WHERE clause.

```
WHERE (([OrderDate] >= N'2012-01-01 00:00:00') AND ([OrderDate] < N'2013-01-01 00:00:00'))
```

To create a partition for the 2013 year

- Follow the steps above, using the following WHERE clause.

```
WHERE (([OrderDate] >= N'2013-01-01 00:00:00') AND ([OrderDate] < N'2014-01-01 00:00:00'))
```

To create a partition for the 2014 year

- Follow the steps above, using the following WHERE clause.

```
WHERE (([OrderDate] >= N'2014-01-01 00:00:00') AND ([OrderDate] < N'2015-01-01 00:00:00'))
```

Delete the FactInternetSales partition

Now that you have partitions for each year, you can delete the FactInternetSales partition. This prevents overlap when choosing Process all when processing partitions.

To delete the FactInternetSales partition

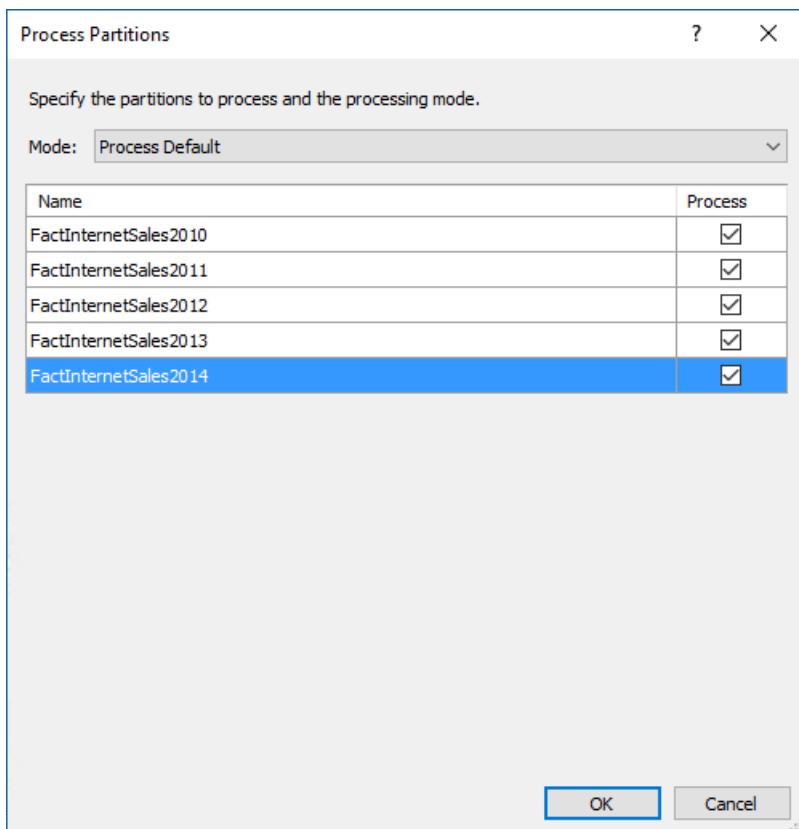

- Click the FactInternetSales partition, and then click **Delete**.

Process partitions

In Partition Manager, notice the **Last Processed** column for each of the new partitions you just created shows these partitions have never been processed. When you create new partitions, you should run a Process Partitions or Process Table operation to refresh the data in those partitions.

To process the FactInternetSales partitions

- Click **OK** to close the Partition Manager dialog box.
- Click the **FactInternetSales** table, then click the **Model** menu > **Process** > **Process Partitions**.
- In the Process Partitions dialog box, verify **Mode** is set to **Process Default**.
- Select the checkbox in the **Process** column for each of the five partitions you created, and then click **OK**.

If you're prompted for Impersonation credentials, enter the Windows user name and password you specified in Lesson 2.

The **Data Processing** dialog box appears and displays process details for each partition. Notice that a different number of rows for each partition are transferred. This is because each partition includes only those rows for the year specified in the WHERE clause in the SQL Statement. When processing is finished, go ahead and close the Data Processing dialog box.

Data Processing ? X

Processing Progress

Processing gets updated data from the original data sources.

Success

| Success | | 5 Total | 0 Cancelled |
|---------|-----------------------|-----------------------------------|-------------|
| | | 5 Success | 0 Error |
| | FactInternetSales2010 | Status | Message |
| | FactInternetSales2011 | Success. 14 rows transferred. | |
| | FactInternetSales2012 | Success. 2,216 rows transferred. | |
| | FactInternetSales2013 | Success. 3,397 rows transferred. | |
| | FactInternetSales2014 | Success. 52,801 rows transferred. | |

Details:

Stop Processing Close

What's next?

Go to the next lesson: [Lesson 11: Create Roles](#).

Lesson 11: Create Roles

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will create roles. Roles provide model database object and data security by limiting access to only those Windows users which are role members. Each role is defined with a single permission: None, Read, Read and Process, Process, or Administrator. Roles can be defined during model authoring by using Role Manager. After a model has been deployed, you can manage roles by using SQL Server Management Studio. To learn more, see [Roles](#).

NOTE

Creating roles is not necessary to complete this tutorial. By default, the account you are currently logged in with will have Administrator privileges on the model. However, to allow other users in your organization to browse the model by using a reporting client, you must create at least one role with Read permissions and add those users as members.

You will create three roles:

- **Sales Manager** - This role can include users in your organization for which you want to have Read permission to all model objects and data.
- **Sales Analyst US** - This role can include users in your organization for which you want only to be able to browse data related to sales in the United States. For this role, you will use a DAX formula to define a *Row Filter*, which restricts members to browse data only for the United States.
- **Administrator** - This role can include users for which you want to have Administrator permission, which allows unlimited access and permissions to perform administrative tasks on the model database.

Because Windows user and group accounts in your organization are unique, you can add accounts from your particular organization to members. However, for this tutorial, you can also leave the members blank. You will still be able to test the effect of each role later in Lesson 12: Analyze in Excel.

Estimated time to complete this lesson: **15 minutes**

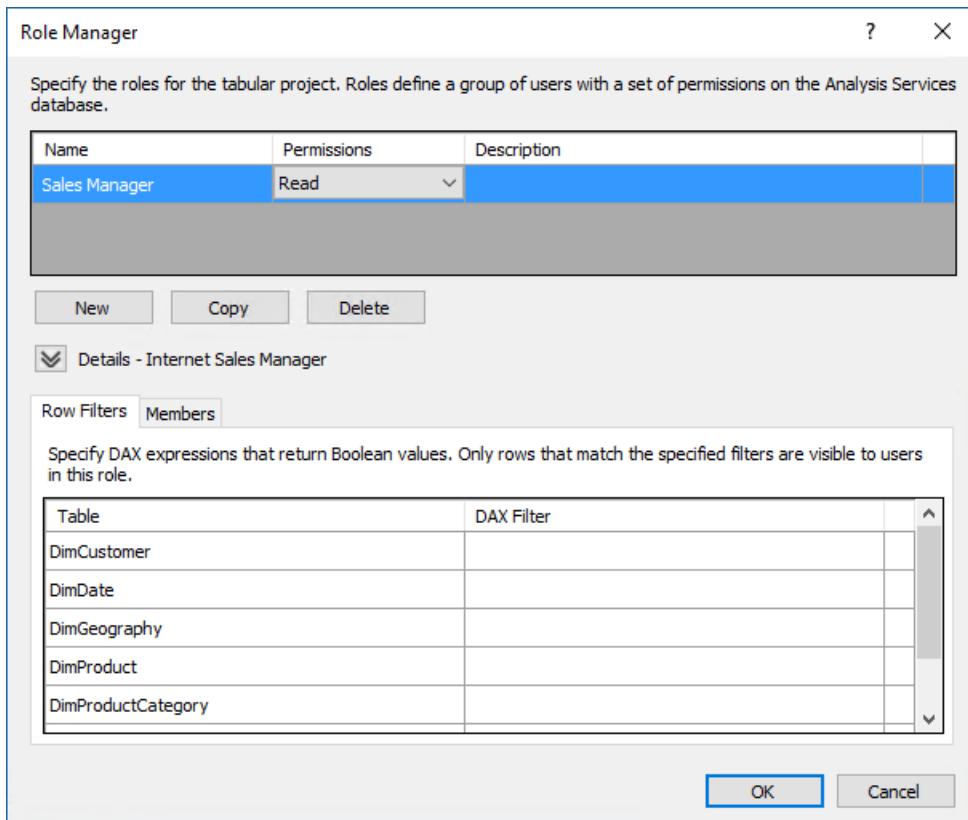

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 10: Create Partitions](#).

Create roles

To create a Sales Manager user role

1. In Tabular Model Explorer, right-click **Roles** > **Roles**.
2. In Role Manager, click **New**.
3. Click on the new role, and then in the **Name** column, rename the role to **Sales Manager**.
4. In the **Permissions** column, click the dropdown list, and then select the **Read** permission.

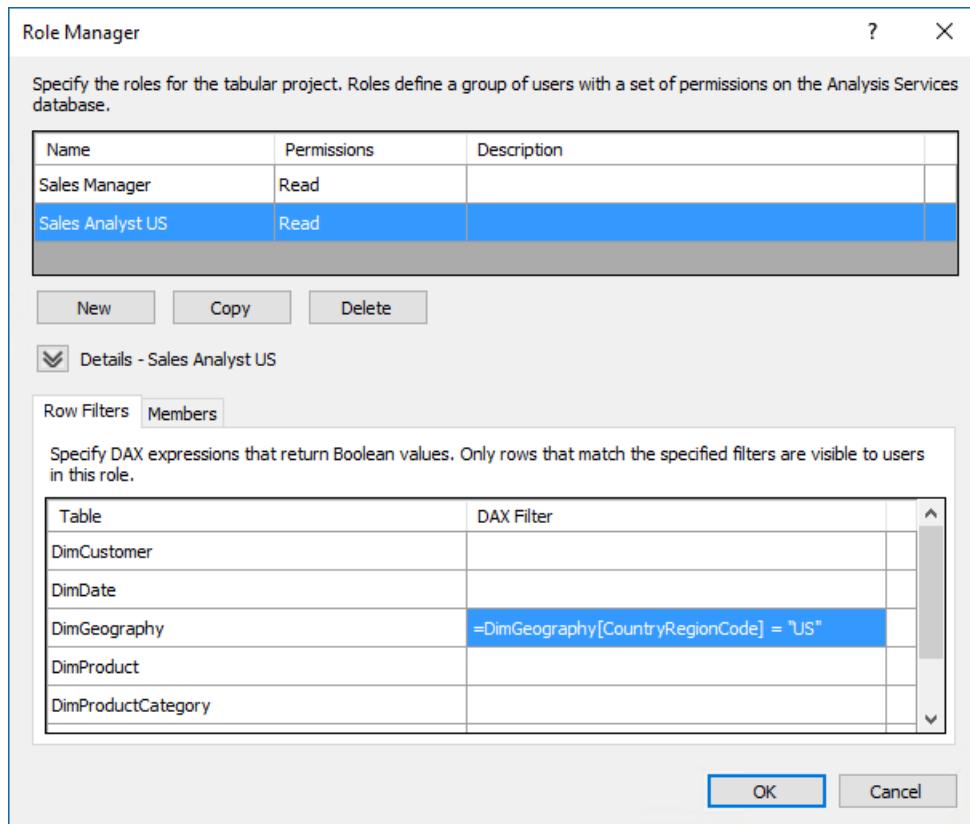

5. Optional: Click the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

To create a **Sales Analyst US** user role

1. In Role Manager, click **New**.
2. Rename the role to **Sales Analyst US**.
3. Give this role **Read** permission.
4. Click on the Row Filters tab, and then for the **DimGeography** table only, in the DAX Filter column, type the following formula:

```
=DimGeography[CountryRegionCode] = "US"
```

A Row Filter formula must resolve to a Boolean (TRUE/FALSE) value. With this formula, you are specifying that only rows with the Country Region Code value of "US" be visible to the user.

5. Optional: Click on the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

To create an Administrator user role

1. Click **New**.
2. Rename the role to **Administrator**.
3. Give this role **Administrator** permission.
4. Optional: Click on the **Members** tab, and then click **Add**. In the **Select Users or Groups** dialog box, enter the Windows users or groups from your organization you want to include in the role.

What's next?

Go to the next lesson: [Lesson 12: Analyze in Excel](#).

Lesson 12: Analyze in Excel (1200 models)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this lesson, you will use the Analyze in Excel feature in SSDT to open Microsoft Excel, automatically create a data source connection to the model workspace, and automatically add a PivotTable to the worksheet. The Analyze in Excel feature is meant to provide a quick and easy way to test the efficacy of your model design prior to deploying your model. You will not perform any data analysis in this lesson. The purpose of this lesson is to familiarize you, the model author, with the tools you can use to test your model design. Unlike using the Analyze in Excel feature, which is meant for model authors, end-users will use client reporting applications like Excel or Power BI to connect to and browse deployed model data.

In order to complete this lesson, Excel must be installed on the same computer as SSDT. To learn more, see [Analyze in Excel](#).

Estimated time to complete this lesson: **20 minutes**

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 11: Create Roles](#).

Browse using the Default and Internet Sales perspectives

In these first tasks, you will browse your model by using both the default perspective, which includes all model objects, and also by using the Internet Sales perspective you earlier. The Internet Sales perspective excludes the Customer table object.

To browse by using the Default perspective

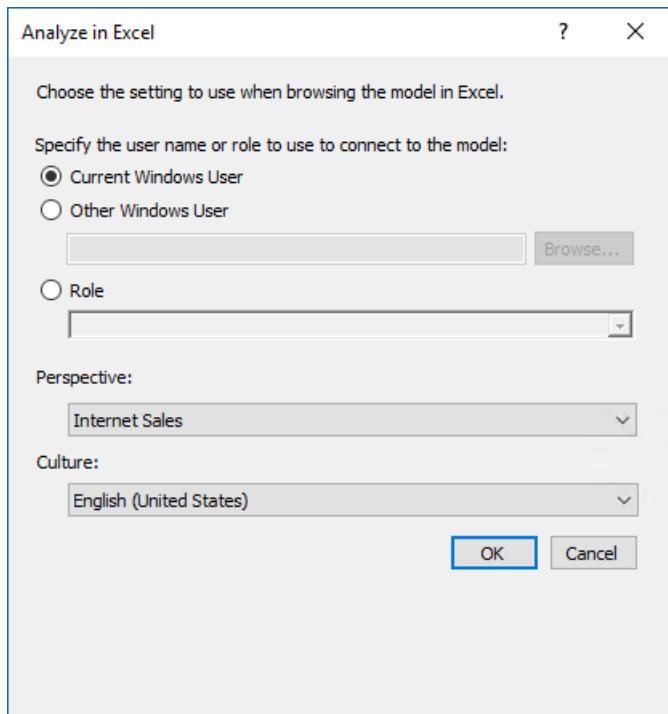

1. Click the **Model** menu > **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, click **OK**.

Excel will open with a new workbook. A data source connection is created using the current user account and the Default perspective is used to define viewable fields. A PivotTable is automatically added to the worksheet.

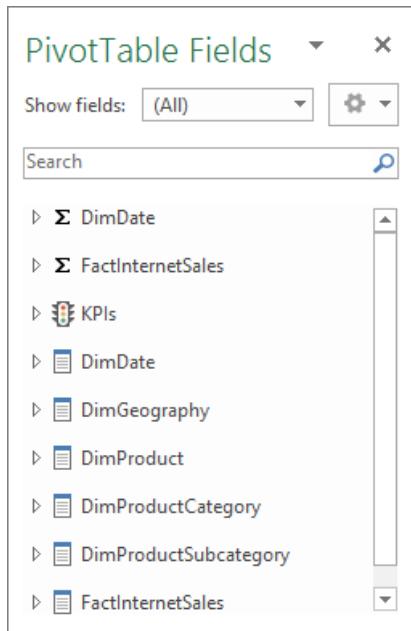

3. In Excel, in the **PivotTable Field List**, notice the **DimDate** and **FactInternetSales** measure groups appear, as well as the **DimCustomer**, **DimDate**, **DimGeography**, **DimProduct**, **DimProductCategory**, **DimProductSubcategory**, and **FactInternetSales** tables with all of their respective columns appear.
4. Close Excel without saving the workbook.

To browse by using the Internet Sales perspective

1. Click the **Model** menu, and then click **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, leave **Current Windows User** selected, then in the **Perspective** dropdown listbox, select **Internet Sales**, and then click **OK**.

3. In Excel, in **PivotTable Fields**, notice the DimCustomer table is excluded from the field list.

4. Close Excel without saving the workbook.

Browse by using roles

Roles are an integral part of any tabular model. Without at least one role to which users are added as members, users will not be able to access and analyze data using your model. The Analyze in Excel feature provides a way for you to test the roles you have defined.

To browse by using the Sales Manager user role

1. In SSDT, click the **Model** menu, and then click **Analyze in Excel**.
2. In the **Analyze in Excel** dialog box, in **Specify the user name or role to use to connect to the model**, select **Role**, and then in the drop-down listbox, select **Sales Manager**, and then click **OK**.

Excel will open with a new workbook. A PivotTable is automatically created. The Pivot Table Field List includes all of the data fields available in your new model.

3. Close Excel without saving the workbook.

What's next?

Go to the next lesson: [Lesson 13: Deploy](#).

Lesson 13: Deploy

10/25/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services (2016 and later) ✓ Azure Analysis Services ✗ Power BI Premium

In this lesson, you will configure deployment properties; specifying an on-premises or Azure server instance, and a name for the model. You'll then deploy the model to that instance. After your model is deployed, users can connect to it by using a reporting client application. To learn more about deploying, see [Tabular model solution deployment](#) and [Deploy to Azure Analysis Services](#).

Estimated time to complete this lesson: **5 minutes**

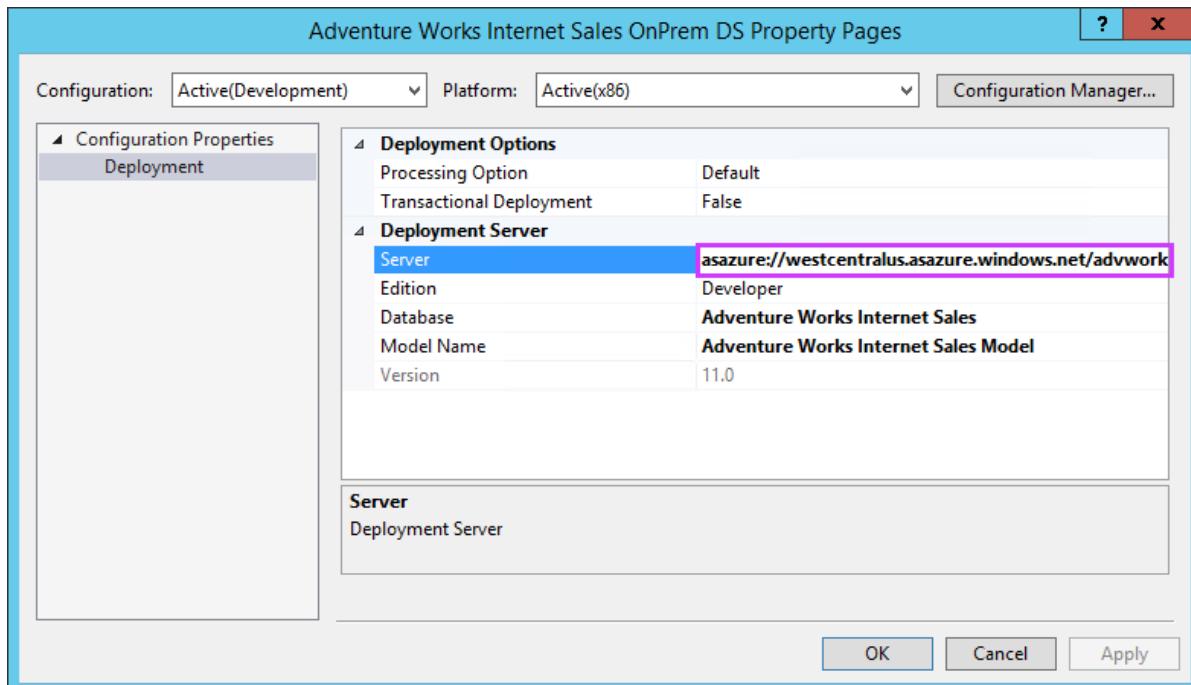

Prerequisites

This topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this lesson, you should have completed the previous lesson: [Lesson 12: Analyze in Excel](#).

Deploy the model

To configure deployment properties

1. In **Solution Explorer**, right-click the **AW Internet Sales** project, and then click **Properties**.
2. In the **AW Internet Sales Property Pages** dialog box, under **Deployment Server**, in the **Server** property, type the name of an Azure Analysis Services server or an on-premises server instance running in Tabular mode. This will be the server instance your model will be deployed to.

IMPORTANT

You must have Administrator permissions on the remote Analysis Services instance in-order to deploy to it.

3. In the **Database** property, type **Adventure Works Internet Sales**.

4. In the **Model Name** property, type **Adventure Works Internet Sales Model**.

5. Verify your selections and then click **OK**.

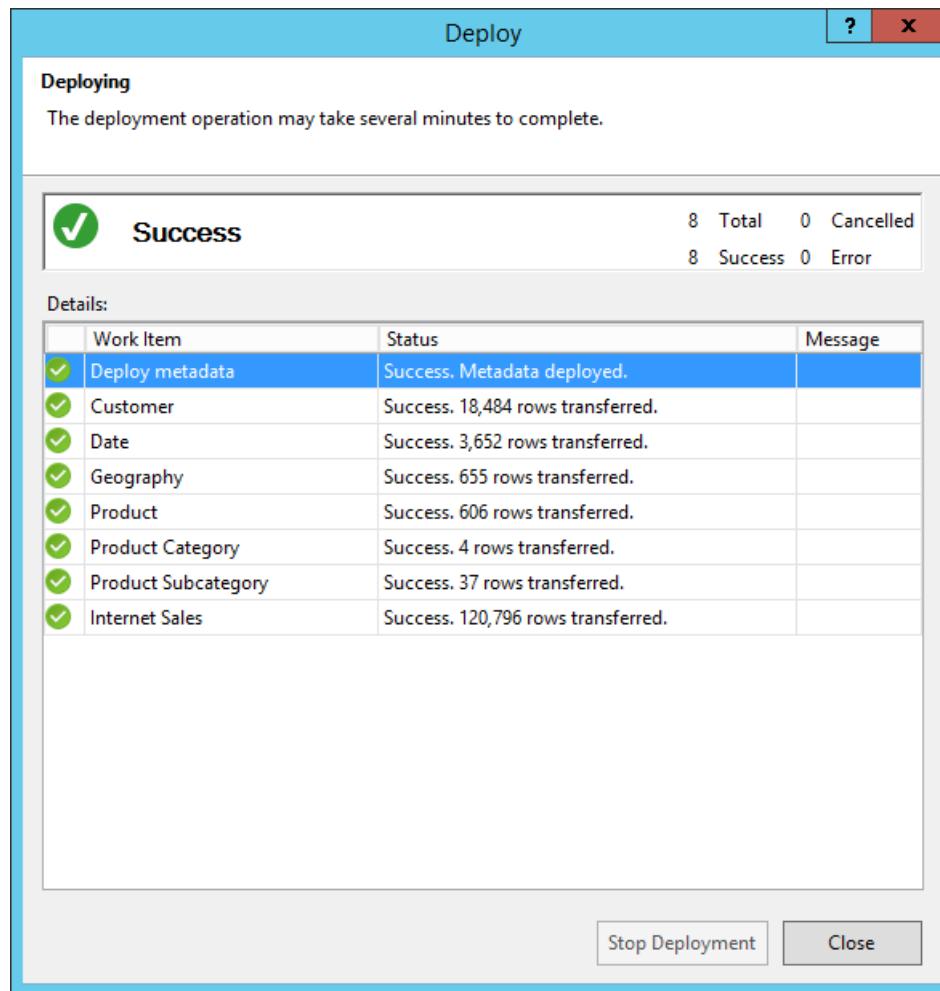

To deploy the Adventure Works Internet Sales tabular model

1. In **Solution Explorer**, right-click the **AW Internet Sales** project > **Build**.

2. Right-click the **AW Internet Sales** project > **Deploy**.

When deploying to Azure Analysis Services, you'll likely be prompted to enter your account. Enter your organizational account and password, for example nancy@adventureworks.com. This account must be in Admins on the server instance.

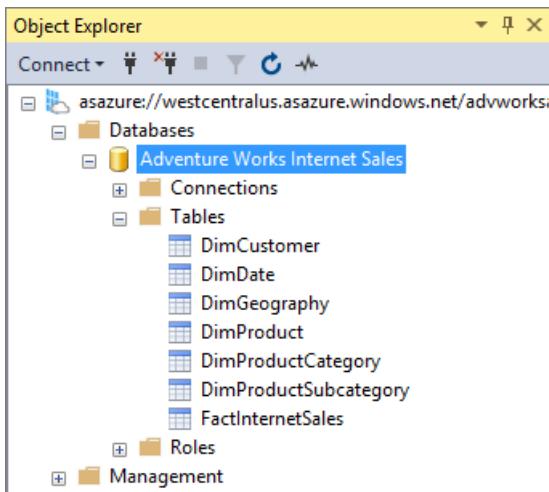

The Deploy dialog box appears and displays the deployment status of the metadata as well as each table included in the model.

3. When deployment successfully completes, go ahead and click **Close**.

Conclusion

Congratulations! You're finished authoring and deploying your first Analysis Services Tabular model. This tutorial has helped guide you through completing the most common tasks in creating a tabular model. Now that your Adventure Works Internet Sales model is deployed, you can use SQL Server Management Studio to manage the model; create process scripts and a backup plan. Users can also now connect to the model using a reporting client application such as Microsoft Excel or Power BI.

What's next?

- [Supplemental Lesson - Implement Dynamic Security by Using Row Filters.](#)

Supplemental Lesson - Implement Dynamic Security by Using Row Filters

7/16/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (2016 and later) Azure Analysis Services Power BI Premium

In this supplemental lesson, you will create an additional role that implements dynamic security. Dynamic security provides row-level security based on the user name or login id of the user currently logged on. To learn more, see [Roles](#).

To implement dynamic security, you must add a table to your model containing the Windows user names of those users that can create a connection to the model as a data source and browse model objects and data. The model you create using this tutorial is in the context of Adventure Works Corp.; however, in order to complete this lesson, you must add a table containing users from your own domain. You will not need the passwords for the user names that will be added. To create an EmployeeSecurity table, with a small sample of users from your own domain, you will use the Paste feature, pasting employee data from an Excel spreadsheet. In a real-world scenario, the table containing user names you add to a model would typically use a table from an actual database as a data source; for example, a real DimEmployee table.

In order to implement dynamic security, you will use two new DAX functions: [USERNAME Function \(DAX\)](#) and [LOOKUPVALUE Function \(DAX\)](#). These functions, applied in a row filter formula, are defined in a new role. Using the LOOKUPVALUE function, the formula specifies a value from the EmployeeSecurity table and then passes that value to the USERNAME function, which specifies the user name of the user logged on belongs to this role. The user can then browse only data specified by the role's row filters. In this scenario, you will specify that sales employees can only browse Internet sales data for the sales territories in which they are a member.

In order to complete this supplemental lesson, you will complete a series of tasks. Those tasks that are unique to this Adventure Works tabular model scenario, but would not necessarily apply to a real-world scenario are identified as such. Each task includes additional information describing the purpose of the task.

Estimated time to complete this lesson: **30 minutes**

Prerequisites

This supplemental lesson topic is part of a tabular modeling tutorial, which should be completed in order. Before performing the tasks in this supplemental lesson, you should have completed all previous lessons.

Add the DimSalesTerritory table to the AW Internet Sales Tabular Model Project

In order to implement dynamic security for this Adventure Works scenario, you must add two additional tables to your model. The first table you will add is DimSalesTerritory (as Sales Territory) from the same AdventureWorksDW database. You will later apply a row filter to the SalesTerritory table that defines the particular data the logged on user can browse.

To add the DimSalesTerritory table

1. In SSDT, click the **Model** menu, and then click **Existing Connections**.
2. In the **Existing Connections** dialog box, verify the **Adventure Works DB from SQL** data source connection is selected, and then click **Open**.

If the Impersonation Credentials dialog box appears, type the impersonation credentials you used in Lesson 2: Add Data.

3. On the **Choose How to Import the Data** page, leave **Select from a list of tables and views to choose the data to import** selected, and then click **Next**.
4. On the **Select Tables and Views** page, select the **DimSalesTerritory** table.
5. Click **Preview and Filter**.
6. Deselect the **SalesTerritoryAlternateKey** column, and then click **Ok**.
7. On the **Select Tables and Views** page, click **Finish**.

The new table will be added to the model workspace. Objects and data from the source DimSalesTerritory table are then imported into your AW Internet Sales Tabular Model.

8. After the table has been imported, click **Close**.

Add a table with user name data

Because the DimEmployee table in the AdventureWorksDW sample database contains users from the AdventureWorks domain, and those user names do not exist in your own environment, you must create a table in your model that contains a small sample (three) of actual users from your organization. You will then add these users as members to the new role. You do not need the passwords for the sample user names, but you will need actual Windows user names from your own domain.

To add an EmployeeSecurity table

1. Open Microsoft Excel, creating a new worksheet.
2. Copy the following table, including the header row, and then paste it into the worksheet.

| EmployeeId | SalesTerritoryId | FirstName | LastName | LoginId |
|--|------------------|-----------|----------|---------|
| 1 2 <user first name> <user last name> \\<domain\username> | | | | |
| 1 3 <user first name> <user last name> \\<domain\username> | | | | |
| 2 4 <user first name> <user last name> \\<domain\username> | | | | |
| 3 5 <user first name> <user last name> \\<domain\username> | | | | |

3. Replace the first name, last name, and domain\username with the names and login ids of three users in your organization. Put the same user on the first two rows, for EmployeeId 1. This will show this user belongs to more than one sales territory. Leave the EmployeeId and SalesTerritoryId fields as they are.
4. Save the worksheet as **SampleEmployee**.
5. In the worksheet, select all of the cells with employee data, including the headers, then right-click the selected data, and then click **Copy**.
6. In SSDT, click the **Edit** menu, and then click **Paste**.

If Paste is grayed out, click any column in any table in the model designer window, and try again.

7. In the **Paste Preview** dialog box, in **Table Name**, type **EmployeeSecurity**.
8. In **Data to be pasted**, verify the data includes all of the user data and headers from the SampleEmployee worksheet.
9. Verify **Use first row as column headers** is checked, and then click **Ok**.

A new table named EmployeeSecurity with employee data copied from the SampleEmployee worksheet is created.

Create relationships between FactInternetSales, DimGeography, and DimSalesTerritory table

The FactInternetSales, DimGeography, and DimSalesTerritory table all contain a common column, SalesTerritoryId. The SalesTerritoryId column in the DimSalesTerritory table contains values with a different Id for each sales territory.

To create relationships between the FactInternetSales, DimGeography, and the DimSalesTerritory table

1. In the model designer, in Diagram View, in the **DimGeography** table, click and hold on the **SalesTerritoryId** column, then drag the cursor to the **SalesTerritoryId** column in the **DimSalesTerritory** table, and then release.
2. In the **FactInternetSales** table, click and hold on the **SalesTerritoryId** column, then drag the cursor to the **SalesTerritoryId** column in the **DimSalesTerritory** table, and then release.

Notice the Active property for this relationship is False, meaning it's inactive. This is because the FactInternetSales table already has another active relationship that is used in measures.

Hide the EmployeeSecurity Table from client applications

In this task, you will hide the EmployeeSecurity table, keeping it from appearing in a client application's field list. Keep in-mind that hiding a table does not secure it. Users can still query EmployeeSecurity table data if they know how. In order to secure the EmployeeSecurity table data, preventing users from being able to query any of its data, you will apply a filter in a later task.

To hide the EmployeeSecurity table from client applications

- In the model designer, in Diagram View, right-click the **Employee** table heading, and then click **Hide from Client Tools**.

Create a Sales Employees by Territory user role

In this task, you will create a new user role. This role will include a row filter defining which rows of the DimSalesTerritory table are visible to users. The filter is then applied in the one-to-many relationship direction to all other tables related to DimSalesTerritory. You will also apply a simple filter that secures the entire EmployeeSecurity table from being queryable by any user that is a member of the role.

NOTE

The Sales Employees by Territory role you create in this lesson restricts members to browse (or query) only sales data for the sales territory to which they belong. If you add a user as a member to the Sales Employees by Territory role that also exists as a member in a role created in [Lesson 11: Create Roles](#), you will get a combination of permissions. When a user is a member of multiple roles, the permissions, and row filters defined for each role are cumulative. That is, the user will have the greater permissions determined by the combination of roles.

To create a Sales Employees by Territory user role

1. In SSDT, click the **Model** menu, and then click **Roles**.
2. In **Role Manager**, click **New**.

A new role with the None permission is added to the list.

3. Click on the new role, and then in the **Name** column, rename the role to **Sales Employees by Territory**.
4. In the **Permissions** column, click the dropdown list, and then select the **Read** permission.
5. Click on the **Members** tab, and then click **Add**.

- In the **Select User or Group** dialog box, in **Enter the object named to select**, type the first sample user name you used when creating the EmployeeSecurity table. Click **Check Names** to verify the user name is valid, and then click **Ok**.

Repeat this step, adding the other sample user names you used when creating the EmployeeSecurity table.

- Click on the **Row Filters** tab.
- For the **EmployeeSecurity** table, in the **DAX Filter** column, type the following formula.

```
=FALSE()
```

This formula specifies that all columns resolve to the false Boolean condition; therefore, no columns for the EmployeeSecurity table can be queried by a member of the Sales Employees by Territory user role.

- For the **DimSalesTerritory** table, type the following formula.

```
='Sales Territory'[Sales Territory Id]=LOOKUPVALUE('Employee Security'[Sales Territory Id],  
'Employee Security'[Login Id], USERNAME(),  
'Employee Security'[Sales Territory Id],  
'Sales Territory'[Sales Territory Id])
```

In this formula, the LOOKUPVALUE function returns all values for the DimEmployeeSecurity[SalesTerritoryId] column, where the EmployeeSecurity[LoginId] is the same as the current logged on Windows user name, and EmployeeSecurity[SalesTerritoryId] is the same as the DimSalesTerritory[SalesTerritoryId].

The set of sales territory IDs returned by LOOKUPVALUE is then used to restrict the rows shown in the DimSalesTerritory table. Only rows where the SalesTerritoryID for the row is in the set of IDs returned by the LOOKUPVALUE function are displayed.

- In Role Manager, click **Ok**.

Test the Sales Employees by Territory User Role

In this task, you will use the Analyze in Excel feature in SSDT to test the efficacy of the Sales Employees by Territory user role. You will specify one of the user names you added to the EmployeeSecurity table and as a member of the role. This user name will then be used as the effective user name in the connection created between Excel and the model.

To test the Sales Employees by Territory user role

- In SSDT, click the **Model** menu, and then click **Analyze in Excel**.
- In the **Analyze in Excel** dialog box, in **Specify the user name or role to use to connect to the model**, select **Other Windows User**, and then click **Browse**.
- In the **Select User or Group** dialog box, in **Enter the object name to select**, type one of the user names you included in the EmployeeSecurity table, and then click **Check Names**.
- Click **Ok** to close the **Select User or Group** dialog box, and then click **Ok** to close the **Analyze in Excel** dialog box.

Excel will open with a new workbook. A PivotTable is automatically created. The PivotTable Fields list includes most of the data fields available in your new model.

Notice the EmployeeSecurity table is not visible in the PivotTable Fields list. This is because you chose to hide this table from client tools in a previous task.

5. In the **Fields** list, in **Σ Internet Sales** (measures), select the **InternetTotalSales** measure. The measure will be entered into the **Values** fields.
6. Select the **SalesTerritoryId** column from the **DimSalesTerritory** table. The column will be entered into the **Row Labels** fields.

Notice Internet sales figures appear only for the one region to which the effective user name you used belongs. If you select another column; for example, City, from the DimGeography table as Row Label field, only cities in the sales territory to which the effective user belongs are displayed.

This user cannot browse or query any Internet sales data for territories other than the one they belong because the row filter defined for the Sales Territory table in the Sales Employees by Territory user role effectively secures data for all data related to other sales territories.

Multidimensional Modeling (Adventure Works Tutorial)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Welcome to the Analysis Services Tutorial. This tutorial describes how to use Visual Studio with Analysis Services projects to develop and deploy an Analysis Services project, using the fictitious company Adventure Works Cycles for all examples.

What you learn

In this tutorial, you will learn the following:

- How to define data sources, data source views, dimensions, attributes, attribute relationships, hierarchies, and cubes in an Analysis Services project within Visual Studio with Analysis Services projects.
- How to view cube and dimension data by deploying the Analysis Services project to an instance of Analysis Services, and how to then process the deployed objects to populate them with data from the underlying data source.
- How to modify the measures, dimensions, hierarchies, attributes, and measure groups in the Analysis Services project, and how to then deploy the incremental changes to the deployed cube on the development server.
- How to define calculations, Key Performance Indicators (KPIs), actions, perspectives, translations, and security roles within a cube.

A scenario description accompanies this tutorial so that you can better understand the context for these lessons. For more information, see [Analysis Services Tutorial Scenario](#).

Prerequisites

You will need sample data, sample project files, and software to complete all of the lessons in this tutorial. For instructions on how to find and install the prerequisites for this tutorial, see [Install Sample Data and Projects for the Analysis Services Multidimensional Modeling Tutorial](#).

Additionally, the following permissions must be in place to successfully complete this tutorial:

- You must be a member of the Administrators local group on the Analysis Services computer or be a member of the server administration role in the instance of Analysis Services.
- You must have Read permissions in the **AdventureWorksDW** sample database. This sample database is valid for the SQL Server 2017 release.

Lessons

This tutorial includes the following lessons.

| LESSON | ESTIMATED TIME TO COMPLETE |
|---|----------------------------|
| Lesson 1: Defining a Data Source View within an Analysis Services Project | 15 minutes |
| Lesson 2: Defining and Deploying a Cube | 30 minutes |
| Lesson 3: Modifying Measures, Attributes and Hierarchies | 45 minutes |
| Lesson 4: Defining Advanced Attribute and Dimension Properties | 120 minutes |
| Lesson 5: Defining Relationships Between Dimensions and Measure Groups | 45 minutes |
| Lesson 6: Defining Calculations | 45 minutes |
| Lesson 7: Defining Key Performance Indicators (KPIs) | 30 minutes |
| Lesson 8: Defining Actions | 30 minutes |
| Lesson 9: Defining Perspectives and Translations | 30 minutes |
| Lesson 10: Defining Administrative Roles | 15 minutes |

NOTE

The cube database that you will create in this tutorial is a simplified version of the Analysis Services multidimensional model project that is part of the Adventure Works sample databases available for download on GitHub. The tutorial version of the Adventure Works multidimensional database is simplified to bring greater focus to the specific skills that you will want to master right away. After you complete the tutorial, consider exploring the multidimensional model project on your own to further your understanding of Analysis Services multidimensional modeling.

Next Step

To begin the tutorial, continue to the first lesson: [Lesson 1: Defining a Data Source View within an Analysis Services Project](#).

Analysis Services Tutorial Scenario

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This tutorial is based on Adventure Works Cycles, a fictitious company. Adventure Works Cycles is a large, multinational manufacturing company that produces and distributes metal and composite bicycles to commercial markets in North America, Europe, and Asia. The headquarters for Adventure Works Cycles is Bothell, Washington, where the company employs 500 workers. Additionally, Adventure Works Cycles employs several regional sales teams throughout its market base.

In recent years, Adventure Works Cycles bought a small manufacturing plant, Importadores Neptuno, which is located in Mexico. Importadores Neptuno manufactures several critical subcomponents for the Adventure Works Cycles product line. These subcomponents are shipped to the Bothell location for final product assembly. In 2005, Importadores Neptuno became the sole manufacturer and distributor of the touring bicycle product group.

Following a successful fiscal year, Adventure Works Cycles now wants to broaden its market share by targeting advertising to its best customers, extending product availability through an external Web site, and reducing the cost of sales by reducing production costs.

Current Analysis Environment

To support the data analysis needs of the sales and marketing teams and of senior management, the company currently takes transactional data from the AdventureWorks2012 database, and non-transactional information such as sales quotas from spreadsheets, and consolidates this information into the **AdventureWorksDW2012** relational data warehouse. However, the relational data warehouse presents the following challenges:

- Reports are static. Users have no way to interactively explore the data in the reports to obtain more detailed information, such as they could do with a Microsoft Office Excel pivot table. Although the existing set of predefined reports is sufficient for many users, more advanced users need direct query access to the database for interactive queries and specialized reports. However, because of the complexity of the **AdventureWorksDW2012** database, too much time is needed for such users to master how to create effective queries.
- Query performance is widely variable. For example, some queries return results very quickly, in only a few seconds, while other queries take several minutes to return.
- Aggregate tables are difficult to manage. In an attempt to improve query response times, the data warehouse team at Adventure Works built several aggregate tables in the **AdventureWorksDW2012** database. For example, they built a table that summarizes sales by month. However, while these aggregate tables greatly improve query performance, the infrastructure that they built to maintain the tables over time is fragile and prone to errors.
- Complex calculation logic is buried in report definitions and is difficult to share between reports. Because this business logic is generated separately for each report, summary information sometimes is different between reports. Therefore, management has limited confidence in the data warehouse reports.
- Users in different business units are interested in different views of the data. Each group is distracted and confused by data elements that are irrelevant to them.
- Calculation logic is particularly challenging for users who need specialized reports. Because such users must define the calculation logic separately for each report, there is no centralized control over how the calculation logic is defined. For example, some users know that they should use basic statistical techniques

such as moving averages, but they do not know how to construct such calculations and so do not use these techniques.

- It is difficult to combine related sets of information. Specialized queries that combine two sets of related information, such as sales and sales quotas, are difficult for business users to construct. Such queries overwhelmed the database, so the company requires that users request cross-subject-area sets of data from the data warehouse team. As a result, only a handful of predefined reports have been defined that combine data from multiple subject areas. Additionally, users are reluctant to try to modify these reports because of their complexity.
- Reports are focused primarily on business information in the United States. Users in the non-U.S. subsidiaries are very dissatisfied with this focus, and want to be able to view reports in different currencies and different languages.
- Information is difficult to audit. The Finance department currently uses the **AdventureWorksDW2012** database only as a source of data from which to query in bulk. They then download the data into individual spreadsheets, and spend significant time preparing the data and manipulating the spreadsheets. The corporate financial reports are therefore difficult to prepare, audit, and manage across the company.

The Solution

The data warehouse team recently performed a design review of the current analysis system. The review included a gap analysis of current issues and future demands. The data warehouse team determined that the **AdventureWorksDW2012** database is a well-designed dimensional database with conformed dimensions and surrogate keys. Conformed dimensions enable a dimension to be used in multiple data marts, such as a time dimension or a product dimension. Surrogate keys are artificial keys that link dimension and fact tables and that are used to ensure uniqueness and to improve performance. Moreover, the data warehouse team determined that there currently are no significant problems with the loading and management of the base tables in the **AdventureWorksDW2012** database. The team has therefore decided to use Microsoft Analysis Services to accomplish the following:

- Provide unified data access through a common metadata layer for analytical analysis and reporting.
- Simplify users' view of data, speeding the development of both interactive and predefined queries and predefined reports.
- Correctly construct queries that combine data from multiple subject areas.
- Manage aggregates.
- Store and reuse complex calculations.
- Present a localized experience to business users outside the United States.

[Multidimensional Modeling \(Adventure Works Tutorial\)](#)

Install sample data and multidimensional projects

10/22/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use the instructions and links provided in this article to install the data and project files used in the Analysis Services tutorials.

Step 1: Install prerequisites

The lessons in this tutorial assume that you have the following software installed. You can install all of the features on a single computer. To install these features, run SQL Server Setup and select them from the Feature Selection page.

- SQL Server Database Engine
- SQL Server Analysis Services (SSAS)

Analysis Services is available in these editions only: Evaluation, Enterprise, Business Intelligence, Standard. Multidimensional models are not supported in Azure Analysis Services.

By default, Analysis Services 2016 and later is installed as a tabular instance. You can override the default mode by choosing Multidimensional Server Mode in the server configuration page of the Installation Wizard.

Step 2: Download and install developer and management tools

Visual Studio is downloaded and installed separately from other SQL Server features. The designers and project templates used to create models are included in the [Analysis Services projects extension](#) for Visual Studio.

[Download Visual Studio.](#)

SQL Server Management Studio (SSMS) is downloaded and installed separately from other SQL Server features.

[Download SQL Server Management Studio](#)

Optionally, consider installing Excel to browse your multidimensional data as you proceed through the tutorial. Installing Excel enables the **Analyze in Excel** feature that starts Excel using a PivotTable field list that is connected to the cube you are building. Using Excel to browse data is recommended because you can quickly build a pivot report that lets you interact with the data.

Alternatively, you can browse data using the built-in MDX query designer that is built into Visual Studio with Analysis Services projects. The query designer returns the same data, except the data is presented as a flat rowset.

Step 3: Install databases

An Analysis Services multidimensional model uses transactional data that you import from a relational database management system. For the purposes of this tutorial, you use the following relational database as your data source.

- **AdventureWorksDW2012 or later** - This is a relational data warehouse that runs on a Database Engine instance. It provides the original data used by the Analysis Services databases and projects that you build and deploy throughout the tutorial. The tutorial assumes you are using AdventureWorksDW2012, however, later versions do work.

You can use this sample database with SQL Server 2012 (11.x) and later. In-general, you should use the sample database version matching your database engine version.

To install the database, do the following:

1. Download an [AdventureWorksDW](#) database backup from GitHub.
2. Copy the backup file to the data directory of the local SQL Server Database Engine instance.
3. Start SQL Server Management Studio and connect to the Database Engine instance.
4. Restore the database.

Step 4: Grant database permissions

The sample projects use data source impersonation settings that specify the security context under which data is imported or processed. By default, the impersonation settings specify the Analysis Services service account for accessing the data. To use this default setting, you must ensure that the service account under which Analysis Services runs has data reader permissions on the **AdventureWorksDW** database.

NOTE

For learning purposes, it is recommended that you use the default service account impersonation option and grant data reader permissions to the service account in SQL Server. Although other impersonation options are available, not all of them are suitable for processing operations. Specifically, the option for using the credentials of the current user is not supported for processing.

1. Determine the service account. You can use SQL Server Configuration Manager or the Services console application to view account information. If you installed Analysis Services as the default instance, using the default account, the service is running as **NT Service\SQLServerOLAPService**.
2. In Management Studio, connect to the database engine instance.
3. Expand the Security folder, right-click Logins and select **New Login**.
4. On the General page, in Login name, type **NT Service\SQLServerOLAPService** (or whatever account the service is running as).
5. Click **User Mapping**.
6. Select the checkbox next to the **AdventureWorksDW** database. Role membership should automatically include **db_datareader** and **public**. Click **OK** to accept the defaults.

Step 5: Install projects

The tutorial includes sample projects so that you can compare your results against a finished project, or start a lesson that is further on in the sequence.

1. Download the [adventure-works-multidimensional-tutorial-projects.zip](#) from the Adventure Works for Analysis Services samples page on GitHub.

The tutorial projects work for SQL Server 2012 (11.x) and later.

2. Move the .zip file to a folder just below the root drive (for example, C:\Tutorial). This step mitigates the "Path too long" error that sometimes occurs if you attempt to unzip the files in the Downloads folder.
3. Unzip the sample projects: right-click on the file and select **Extract All**. After extracting the files, you should have folders Lesson 1, 2, 3, 5, 6, 7, 8, 9, 10 Complete and Lesson 4 Start.

4. Remove the read-only permissions on these files. Right-click the parent folder, select **Properties**, and clear the checkbox for **Read-only**. Click **OK**. Apply the changes to this folder, subfolders, and files.
5. Open the solution (.sln) file that corresponds to the lesson you are in. For example, in the folder named "Lesson 1 Complete", you would open the Analysis Services Tutorial.sln file.
6. Deploy the solution to verify that database permissions and server location information are setup correctly.

If Analysis Services and the Database Engine are installed as the default instance (MSSQLServer) and all software is running on the same computer, you can click **Deploy Solution** on the Build menu to build and deploy the sample project to the local Analysis Services instance. During deployment, data is processed (or imported) from the **AdventureWorksDW** database on the local Database Engine instance. A new Analysis Services database is created on the Analysis Services instance that contains the data retrieved from the Database Engine.

If you encounter errors, review the previous steps on setting up database permissions. Additionally, you might also need to change server names. The default server name is localhost. If your servers are installed on remote computers or as named instances, you must override the default to use a server name that is valid for your installation. Furthermore, if the servers are on remote computers, you might need to configure Windows Firewall to allow access to the servers.

The server name for connecting to the database engine is specified in the Data Source object of the multidimensional solution (Adventure Works Tutorial), visible in Solution Explorer.

The server name for connecting to Analysis Services is specified in the Deployment tab of the Property Pages of the project, also visible in Solution Explorer.

7. In SQL Server Management Studio, connect to Analysis Services. Verify the database named **Analysis Services Tutorial** is running on the server.

Next step

You are now ready to use the tutorial. For more information about how to get started, see [Multidimensional Modeling \(Adventure Works Tutorial\)](#).

[Configure the Windows Firewall to Allow SQL Server Access](#)

Lesson 1: Defining a Data Source View within an Analysis Services Project

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Designing a business intelligence application in SQL Server starts with creating an Analysis Services project in Visual Studio with Analysis Services projects. Within this project, you define all the elements of your solution, starting with a data source view.

This lesson contains the following tasks:

[Creating an Analysis Services Project](#)

In this task, you create the Analysis Services Tutorial project, based on an Analysis Services multidimensional model template.

[Defining a Data Source](#)

In this task, you specify the **AdventureWorksDW** database as the data source for the Analysis Services dimensions and cubes that you define in subsequent lessons.

[Defining a Data Source View](#)

In this task, you define a single unified view of the metadata from selected tables in the **AdventureWorksDW** database.

[Modifying Default Table Names](#)

In this task, you modify table names in the data source view, so that the names of subsequent Analysis Services objects that you define are more user-friendly.

Next Lesson

[Lesson 2: Defining and Deploying a Cube](#)

Lesson 1-1 - Creating an Analysis Services Project

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the following task, you use Visual Studio with Analysis Services projects to create a new Analysis Services project named **Analysis Services Tutorial**, based on the Analysis Services Project template. A *project* is a collection of related objects. Projects exist within a solution, which includes one or more projects. For more information, see [Create an Analysis Services Project \(SSDT\)](#).

To create a new Analysis Services project

1. Open SQL Server Data Tools.
2. Create a new Analysis Services Multidimensional project. Choose the **Analysis Services Multidimensional and Data Mining Project** template.

Notice the default project name, location, and the default solution name are generated in the bottom of the dialog box. By default, a new directory is created for the solution.

3. Change the project Name to **Analysis Services Tutorial**, which also changes the **Solution name** box, and then click **OK**.

You have successfully created the **Analysis Services Tutorial** project, based on the **Analysis Services Multidimensional and Data Mining Project** template, within a new solution that is also named **Analysis Services Tutorial**.

Next Task in Lesson

[Defining a Data Source](#)

See Also

[Creating Multidimensional Models Using SQL Server Data Tools \(SSDT\)](#)

[Create an Analysis Services Project \(SSDT\)](#)

Lesson 1-2 - Defining a Data Source

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

After you create an Analysis Services project, you generally start working with the project by defining one or more data sources that the project will use. When you define a data source, you are defining the connection string information that will be used to connect to the data source. For more information, see [Create a Data Source \(SSAS Multidimensional\)](#).

In the following task, you define the AdventureWorksDWSQLServer2012 sample database as the data source for the Analysis Services Tutorial project. While this database is located on your local computer for the purposes of this tutorial, source databases are frequently hosted on one or more remote computers.

To define a new data source

1. In Solution Explorer (on the right of the Microsoft Visual Studio window), right-click **Data Sources**, and then click **New Data Source**.
2. On the **Welcome to the Data Source Wizard** page of the **Data Source Wizard**, click **Next** to open the **Select how to define the connection** page.
3. On the **Select how to define the connection** page, you can define a data source based on a new connection, based on an existing connection, or based on a previously defined data source object. In this tutorial, you define a data source based on a new connection. Verify that **Create a data source based on an existing or new connection** is selected, and then click **New**.
4. In the **Connection Manager** dialog box, you define connection properties for the data source. In the **Provider** list box, verify that **Native OLE DB\SQL Server Native Client 11.0** is selected.

Analysis Services also supports other providers, which are displayed in the **Provider** list.

5. In the **Server name** text box, type **localhost**.

To connect to a named instance on your local computer, type **localhost**. To connect to the specific computer instead of the local computer, type the computer name or IP address.

6. Verify that **Use Windows Authentication** is selected. In the **Select or enter a database name** list, select **AdventureWorksDW2012**.
7. Click **Test Connection** to test the connection to the database.
8. Click **OK**, and then click **Next**.
9. On the **Impersonation Information** page of the wizard, you define the security credentials for Analysis Services to use to connect to the data source. Impersonation affects the Windows account used to connect to the data source when Windows Authentication is selected. Analysis Services does not support impersonation for processing OLAP objects. Select **Use the service account**, and then click **Next**.
10. On the **Completing the Wizard** page, accept the default name, **Adventure Works DW 2012**, and then click **Finish** to create the new data source.

NOTE

To modify the properties of the data source after it has been created, double-click the data source in the **Data Sources** folder to display the data source properties in **Data Source Designer**.

Next Task in Lesson

[Defining a Data Source View](#)

See Also

[Create a Data Source \(SSAS Multidimensional\)](#)

Lesson 1-3 - Defining a Data Source View

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you define the data sources that you will use in an Analysis Services project, the next step is generally to define a data source view for the project. A data source view is a single, unified view of the metadata from the specified tables and views that the data source defines in the project. Storing the metadata in the data source view enables you to work with the metadata during development without an open connection to any underlying data source. For more information, see [Data Source Views in Multidimensional Models](#).

In the following task, you define a data source view that includes five tables from the **AdventureWorksDW2012** data source.

To define a new data source view

1. In Solution Explorer (on the right of the Microsoft Visual Studio window), right-click **Data Source Views**, and then click **New Data Source View**.
2. On the **Welcome to the Data Source View Wizard** page, click **Next**. The **Select a Data Source** page appears.
3. Under **Relational data sources**, the **Adventure Works DW 2012** data source is selected. Click **Next**.

NOTE

To create a data source view that is based on multiple data sources, first define a data source view that is based on a single data source. This data source is then called the primary data source. You can then add tables and views from a secondary data source. When designing dimensions that contain attributes based on related tables in multiple data sources, you might need to define a MicrosoftSQL Server data source as the primary data source to use its distributed query engine capabilities.

4. On the **Select Tables and Views** page, select tables and views from the list of objects that are available from the selected data source. You can filter this list to help you select tables and views.

NOTE

Click the maximize button in the upper-right corner so that the window covers the full screen. This makes it easier to see the complete list of available objects.

In the **Available objects** list, select the following objects. You can select multiple tables by clicking each while holding down the CTRL key:

- **DimCustomer (dbo)**
 - **DimDate (dbo)**
 - **DimGeography (dbo)**
 - **DimProduct (dbo)**
 - **FactInternetSales (dbo)**
5. Click > to add the selected tables to the **Included objects** list.

6. Click **Next**.

7. In the Name field, make sure **Adventure Works DW 2012** displays, and then click **Finish**.

The **Adventure Works DW 2012** data source view appears in the **Data Source Views** folder in Solution Explorer. The content of the data source view is also displayed in Data Source View Designer in Visual Studio with Analysis Services projects. This designer contains the following elements:

- A **Diagram** pane in which the tables and their relationships are represented graphically.
- A **Tables** pane in which the tables and their schema elements are displayed in a tree view.
- A **Diagram Organizer** pane in which you can create subdiagrams so that you can view subsets of the data source view.
- A toolbar that is specific to Data Source View Designer.

8. To maximize the Microsoft Visual Studio development environment, click the **Maximize** button.

9. To view the tables in the **Diagram** pane at 50 percent, click the **Zoom** icon on the Data Source View Designer toolbar. This will hide the column details of each table.

10. To hide Solution Explorer, click the **Auto Hide** button, which is the pushpin icon on the title bar. To view Solution Explorer again, position your pointer over the Solution Explorer tab along the right side of the development environment. To unhide Solution Explorer, click the **Auto Hide** button again.

11. If the windows are not hidden by default, click **Auto Hide** on the title bar of the Properties and Solution Explorer windows.

You can now view all the tables and their relationships in the **Diagram** pane. Notice that there are three relationships between the FactInternetSales table and the DimDate table. Each sale has three dates associated with the sale: an order date, a due date, and a ship date. To view the details of any relationship, double-click the relationship arrow in the **Diagram** pane.

Next Task in Lesson

[Modifying Default Table Names](#)

See Also

[Data Source Views in Multidimensional Models](#)

Lesson 1-4 - Modifying Default Table Names

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can change the value of the **FriendlyName** property for objects in the data source view to make them easier to notice and use.

In the following task, you will change the friendly name of each table in the data source view by removing the "**Dim**" and "**Fact**" prefixes from these tables. This will make the cube and dimension objects (that you will define in the next lesson) easier to notice and use.

NOTE

You can also change the friendly names of columns, define calculated columns, and join tables or views in the data source view to make them easier to use.

To modify the default name of a table

1. In the **Tables** pane of **Data Source View Designer**, right-click the **FactInternetSales** table, and then click **Properties**.
2. If the Properties window on the right side of the Microsoft Visual Studio window is not displayed, click the **Auto Hide** button on the title bar of the Properties window so that this window remains visible.

It is easier to change the properties for each table in the data source view when the Properties window remains open. If you do not pin the window open by using the **Auto Hide** button, the window will close when you click a different object in the **Diagram** pane.

3. Change the **FriendlyName** property for the **FactInternetSales** object to **InternetSales**.

When you click away from the cell for the **FriendlyName** property, the change is applied. In the next lesson, you will define a measure group that is based on this fact table. The name of the fact table will be **InternetSales** instead of **FactInternetSales** because of the change you made in this lesson.

4. Click **DimProduct** in the **Tables** pane. In the Properties window, change the **FriendlyName** property to **Product**.
5. Change the **FriendlyName** property of each remaining table in the data source view in the same way, to remove the "**Dim**" prefix.
6. When you have finished, click the **Auto Hide** button to hide the Properties window again.
7. On the **File** menu, or on the toolbar of Visual Studio with Analysis Services projects, click **Save All** to save the changes you have made to this point in the Analysis Services Tutorial project. You can stop the tutorial here if you want and resume it later.

Change Properties in a Data Source View (Analysis Services)

Lesson 2: Defining and Deploying a Cube

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you define a data source view in your Microsoft Analysis Services project, you are ready to define an initial Analysis Services cube.

You can define a cube and its dimensions in a single pass using the Cube Wizard. Alternatively, you can define one or more dimensions and then use the Cube Wizard to define a cube that uses those dimensions. If you are designing a complex solution, you generally start by defining the dimensions. For more information, see [Dimensions in Multidimensional Models](#) or [Cubes in Multidimensional Models](#).

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

This lesson contains the following tasks:

[Defining a Dimension](#)

In this task, you use the Dimension Wizard to define a dimension.

[Defining a Cube](#)

In this task, you use the Cube Wizard to define an initial Analysis Services cube.

[Adding Attributes to Dimensions](#)

In this task, you add attributes to the dimensions that you created.

[Reviewing Cube and Dimension Properties](#)

In this task, you review the structure of the cube that you defined by using the Cube Wizard.

[Deploying an Analysis Services Project](#)

In this task, you deploy the Analysis Services project to your local instance of Analysis Services, and learn about certain deployment properties.

[Browsing the Cube](#)

In this task, you browse the cube and dimension data by using Excel or the MDX query designer.

Deploy Analysis Services Projects (SSDT)

Lesson 2-1 - Defining a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In the following task, you will use the Dimension Wizard to build a Date dimension.

NOTE

This lesson requires that you have completed all the procedures in Lesson 1.

To define a dimension

1. In Solution Explorer (on the right side of Microsoft Visual Studio), right-click **Dimensions**, and then click **New Dimension**. The Dimension Wizard appears.
2. On the **Welcome to the Dimension Wizard** page, click **Next**.
3. On the **Select Creation Method** page, verify that the **Use an existing table** option is selected, and then click **Next**.
4. On the **Specify Source Information** page, verify that the **Adventure Works DW 2012** data source view is selected.
5. In the **Main table** list, select **Date**.
6. Click **Next**.
7. On the **Select Dimension Attributes** page, select the check boxes next to the following attributes:
 - **Date Key**
 - **Full Date Alternate Key**
 - **English Month Name**
 - **Calendar Quarter**
 - **Calendar Year**
 - **Calendar Semester**
8. Change the setting of the **Full Date Alternate Key** attribute's **Attribute Type** column from **Regular** to **Date**. To do this, click **Regular** in the **Attribute Type** column. Then click the arrow to expand the options. Next, click **Date > Calendar > Date**. Click **OK**. Repeat these steps to change the attribute type of the attributes as follows:
 - **English Month Name** to **Month**
 - **Calendar Quarter** to **Quarter**
 - **Calendar Year** to **Year**
 - **Calendar Semester** to **Half Year**
9. Click **Next**.
10. On the **Completing the Wizard** page, in the Preview pane, you can see the **Date** dimension and its

attributes.

11. Click **Finish** to complete the wizard.

In Solution Explorer, in the Analysis Services Tutorial project, the Date dimension appears in the **Dimensions** folder. In the center of the development environment, Dimension Designer displays the Date dimension.

12. On the **File** menu, click **Save All**.

Next Task in Lesson

[Defining a Cube](#)

See Also

[Dimensions in Multidimensional Models](#)

[Create a Dimension by Using an Existing Table](#)

[Create a Dimension Using the Dimension Wizard](#)

Lesson 2-2 - Defining a Cube

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Cube Wizard helps you define the measure groups and dimensions for a cube. In the following task, you will use the Cube Wizard to build a cube.

To define a cube and its properties

1. In Solution Explorer, right-click **Cubes**, and then click **New Cube**. The Cube Wizard appears.
2. On the **Welcome to the Cube Wizard** page, click **Next**.
3. On the **Select Creation Method** page, verify that the **Use existing tables** option is selected, and then click **Next**.
4. On the **Select Measure Group Tables** page, verify that the **Adventure Works DW 2012** data source view is selected.
5. Click **Suggest** to have the cube wizard suggest tables to use to create measure groups.

The wizard examines the tables and suggests **InternetSales** as a measure group table. Measure group tables, also called fact tables, contain the measures you are interested in, such as the number of units sold.

6. Click **Next**.
7. On the **Select Measures** page, review the selected measures in the **Internet Sales** measure group, and then clear the check boxes for the following measures:
 - **Promotion Key**
 - **Currency Key**
 - **Sales Territory Key**
 - **Revision Number**

By default, the wizard selects as measures all numeric columns in the fact table that are not linked to dimensions. However, these four columns are not actual measures. The first three are key values that link the fact table with dimension tables that are not used in the initial version of this cube.

8. Click **Next**.
9. On the **Select Existing Dimensions** page, make sure the **Date** dimension that you created earlier is selected, and then click **Next**.
10. On the **Select New Dimensions** page, select the new dimensions to be created. To do this, verify that the **Customer**, **Geography**, and **Product** check boxes are selected, and then clear the **InternetSales** check box.
11. Click **Next**.
12. On the **Completing the Wizard** page, change the name of the cube to **Analysis Services Tutorial**. In the Preview pane, you can see the **InternetSales** measure group and its measures. You can also see the **Date**, **Customer**, and **Product** dimensions.
13. Click **Finish** to complete the wizard.

In Solution Explorer, in the Analysis Services Tutorial project, the Analysis Services Tutorial cube appears in the **Cubes** folder, and the Customer and Product database dimensions appear in the **Dimensions** folder. Additionally, in the center of the development environment, the Cube Structure tab displays the Analysis Services Tutorial cube.

14. On the toolbar of the Cube Structure tab, change the **Zoom** level to 50 percent, so that you can more easily see the dimensions and fact tables in the cube. Notice that the fact table is yellow and the dimension tables are blue.
15. On the **File** menu, click **Save All**.

Next Task in Lesson

[Adding Attributes to Dimensions](#)

See Also

[Cubes in Multidimensional Models](#)

[Dimensions in Multidimensional Models](#)

Lesson 2-3 - Adding Attributes to Dimensions

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Now that you have defined dimensions, you can populate them with attributes that represent each data element in the dimension. Attributes are commonly based on fields from a data source view. When adding attributes to a dimension, you can include fields from any table in the data source view.

In this task, you will use Dimension Designer to add attributes to the Customer and Product dimensions. The Customer dimension will include attributes based on fields from both the Customer and Geography tables.

Adding Attributes to the Customer Dimension

To add attributes

1. Open Dimension Designer for the Customer dimension. To do this, double-click the **Customer** dimension in the **Dimensions** node of Solution Explorer.
2. In the **Attributes** pane, notice the Customer Key and Geography Key attributes that were created by the Cube Wizard.
3. On the toolbar of the **Dimension Structure** tab, make sure the Zoom icon to view the tables in the **Data Source View** pane is set at 100 percent.
4. Drag the following columns from the **Customer** table in the **Data Source View** pane to the **Attributes** pane:
 - **BirthDate**
 - **MaritalStatus**
 - **Gender**
 - **EmailAddress**
 - **YearlyIncome**
 - **TotalChildren**
 - **NumberChildrenAtHome**
 - **EnglishEducation**
 - **EnglishOccupation**
 - **HouseOwnerFlag**
 - **NumberCarsOwned**
 - **Phone**
 - **DateFirstPurchase**
 - **CommuteDistance**
5. Drag the following columns from the **Geography** table in the **Data Source View** pane to the **Attributes** pane:

- **City**
- **StateProvinceName**
- **EnglishCountryRegionName**
- **PostalCode**

6. On the File menu, click **Save All**.

Adding Attributes to the Product Dimension

To add attributes

1. Open Dimension Designer for the Product dimension. Double-click the **Product** dimension in Solution Explorer.
2. In the **Attributes** pane, notice the Product Key attribute that was created by the Cube Wizard.
3. On the toolbar of the **Dimension Structure** tab, make sure the Zoom icon to view the tables in the **Data Source View** pane is set at 100 percent.
4. Drag the following columns from the **Product** table in the **Data Source View** pane to the **Attributes** pane:
 - **StandardCost**
 - **Color**
 - **SafetyStockLevel**
 - **ReorderPoint**
 - **ListPrice**
 - **Size**
 - **SizeRange**
 - **Weight**
 - **DaysToManufacture**
 - **ProductLine**
 - **DealerPrice**
 - **Class**
 - **Style**
 - **ModelName**
 - **StartDate**
 - **EndDate**
 - **Status**

5. On the File menu, click **Save All**.

Next Task in Lesson

[Reviewing Cube and Dimension Properties](#)

See Also

[Dimension Attribute Properties Reference](#)

Lesson 2-4 - Reviewing Cube and Dimension Properties

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you have defined a cube, you can review the results by using Cube Designer. In the following task, you review the structure of the cube in the Analysis Services Tutorial project.

To review cube and dimension properties in Cube Designer

1. To open the Cube Designer, double-click the **Analysis Services Tutorial** cube in the **Cubes** node of Solution Explorer.
2. In the **Measures** pane of the **Cube Structure** tab in Cube Designer, expand the **Internet Sales** measure group to reveal the defined measures.

You can change the order by dragging the measures into the order that you want. The order you create affects how certain client applications order these measures. The measure group and each measure that it contains have properties that you can edit in the Properties window.

3. In the **Dimensions** pane of the **Cube Structure** tab in Cube Designer, review the cube dimensions that are in the Analysis Services Tutorial cube.

Notice that although only three dimensions were created at the database level, as displayed in Solution Explorer, there are five cube dimensions in the Analysis Services Tutorial cube. The cube contains more dimensions than the database because the Date database dimension is used as the basis for three separate date-related cube dimensions, based on different date-related facts in the fact table. These date-related dimensions are also called *role playing dimensions*. The three date-related cube dimensions let users dimension the cube by three separate facts that are related to each product sale: the product order date, the due date for fulfillment of the order, and the ship date for the order. By reusing a single database dimension for multiple cube dimensions, Analysis Services simplifies dimension management, uses less disk space, and reduces overall processing time.

4. In the **Dimensions** pane of the **Cube Structure** tab, expand **Customer**, and then click **Edit Customer** to open the dimension in Dimension Designer.

Dimension Designer contains these tabs: **Dimension Structure**, **Attribute Relationships**, **Translations**, and **Browser**. Notice that the **Dimension Structure** tab includes three panes: **Attributes**, **Hierarchies**, and **Data Source View**. The attributes that the dimension contains appear in the **Attributes** pane. For more information, see [Dimension Attribute Properties Reference](#), [Create User-Defined Hierarchies](#), and [Define Attribute Relationships](#).

5. To switch to Cube Designer, right-click the **Analysis Services Tutorial** cube in the **Cubes** node in Solution Explorer, and then click **View Designer**.
6. In Cube Designer, click the **Dimension Usage** tab.

In this view of the Analysis Services Tutorial cube, you can see the cube dimensions that are used by the Internet Sales measure group. Also, you can define the type of relationship between each dimension and each measure group in which it is used.

7. Click the **Partitions** tab.

The Cube Wizard defines a single partition for the cube, by using the multidimensional online analytical processing (MOLAP) storage mode without aggregations. With MOLAP, all leaf-level data and all aggregations are stored within the cube for maximum performance. Aggregations are precalculated summaries of data that improve query response time by having answers ready before questions are asked. You can define additional partitions, storage settings, and writeback settings on the **Partitions** tab. For more information, see [Partitions \(Analysis Services - Multidimensional Data\)](#), [Aggregations and Aggregation Designs](#).

8. Click the **Browser** tab.

Notice that the cube cannot be browsed because it has not yet been deployed to an instance of Analysis Services. At this point, the cube in the Analysis Services Tutorial project is just a definition of a cube, which you can deploy to any instance of Analysis Services. When you deploy and process a cube, you create the defined objects in an instance of Analysis Services and populate the objects with data from the underlying data sources.

9. In Solution Explorer, right-click **Analysis Services Tutorial** in the **Cubes** node, and then click **View Code**. You might need to wait.

The XML code for the Analysis Services Tutorial cube is displayed on the **Analysis Services Tutorial.cube [XML]** tab. This is the actual code that is used to create the cube in an instance of Analysis Services during deployment. For more information, see [View the XML for an Analysis Services Project \(SSDT\)](#).

10. Close the XML code tab.

Next Task in Lesson

[Deploying an Analysis Services Project](#)

See Also

[Browse Dimension Data in Dimension Designer](#)

Lesson 2-5 - Deploying an Analysis Services Project

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

To view the cube and dimension data for the objects in the Analysis Services Tutorial cube in the Analysis Services Tutorial project, you must deploy the project to a specified instance of Analysis Services and then process the cube and its dimensions. *Deploying* an Analysis Services project creates the defined objects in an instance of Analysis Services. *Processing* the objects in an instance of Analysis Services copies the data from the underlying data sources into the cube objects. For more information, see [Deploy Analysis Services Projects \(SSDT\)](#) and [Configure Analysis Services Project Properties \(SSDT\)](#).

At this point in the development process, you generally deploy the cube to an instance of Analysis Services on a development server. Once you have finished developing your business intelligence project, you will generally use the Analysis Services Deployment Wizard to deploy your project from the development server to a production server. For more information, see [Multidimensional Model Solution Deployment](#) and [Deploy Model Solutions Using the Deployment Wizard](#).

In the following task, you review the deployment properties of the Analysis Services Tutorial project and then deploy the project to your local instance of Analysis Services.

To deploy the Analysis Services project

1. In Solution Explorer, right-click the **Analysis Services Tutorial** project, and then click **Properties**.

The **Analysis Services Tutorial Property Pages** dialog box appears and displays the properties of the Active(Development) configuration. You can define multiple configurations, each with different properties. For example, a developer might want to configure the same project to deploy to different development computers and with different deployment properties, such as database names or processing properties. Notice the value for the **Output Path** property. This property specifies the location in which the XMLA deployment scripts for the project are saved when a project is built. These are the scripts that are used to deploy the objects in the project to an instance of Analysis Services.

2. In the **Configuration Properties** node in the left pane, click **Deployment**.

Review the deployment properties for the project. By default, the Analysis Services Project template configures an Analysis Services project to incrementally deploy all projects to the default instance of Analysis Services on the local computer, to create an Analysis Services database with the same name as the project, and to process the objects after deployment by using the default processing option. For more information, see [Configure Analysis Services Project Properties \(SSDT\)](#).

NOTE

If you want to deploy the project to a named instance of Analysis Services on the local computer, or to an instance on a remote server, change the **Server** property to the appropriate instance name, such as <ServerName*>\<InstanceName>*.

3. Click **OK**.
4. In Solution Explorer, right-click the **Analysis Services Tutorial** project, and then click **Deploy**. You might need to wait.

NOTE

If you get errors during deployment, use SQL Server Management Studio to check the database permissions. The account you specified for the data source connection must have a login on the SQL Server instance. Double-click the login to view User Mapping properties. The account must have db_datareader permissions on the **AdventureWorksDW2012** database.

Visual Studio with Analysis Services projects builds and then deploys the Analysis Services Tutorial project to the specified instance of Analysis Services by using a deployment script. The progress of the deployment is displayed in two windows: the **Output** window and the **Deployment Progress - Analysis Services Tutorial** window.

Open the Output window, if necessary, by clicking **Output** on the **View** menu. The **Output** window displays the overall progress of the deployment. The **Deployment Progress - Analysis Services Tutorial** window displays the detail about each step taken during deployment. For more information, see [Build Analysis Services Projects \(SSDT\)](#) and [Deploy Analysis Services Projects \(SSDT\)](#).

5. Review the contents of the **Output** window and the **Deployment Progress - Analysis Services Tutorial** window to verify that the cube was built, deployed, and processed without errors.
6. To hide the **Deployment Progress - Analysis Services Tutorial** window, click the **Auto Hide** icon (it looks like a pushpin) on the toolbar of the window.
7. To hide the **Output** window, click the **Auto Hide** icon on the toolbar of the window.

You have successfully deployed the Analysis Services Tutorial cube to your local instance of Analysis Services, and then processed the deployed cube.

Next Task in Lesson

[Browsing the Cube](#)

See Also

[Deploy Analysis Services Projects \(SSDT\)](#)

[Configure Analysis Services Project Properties \(SSDT\)](#)

Lesson 2-6 - Browsing the Cube

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

After you deploy a cube, the cube data is viewable on the **Browser** tab in Cube Designer, and the dimension data is viewable on the **Browser** tab in Dimension Designer. Browsing cube and dimension data is way to check your work incrementally. You can verify that small changes to properties, relationships, and other objects have the desired effect once the object is processed. While the Browser tab is used to view both cube and dimension data, the tab provides different capabilities based on the object you are browsing.

For dimensions, the Browser tab provides a way to view members or navigate a hierarchy all the way down to the leaf node. You can browse dimension data in different languages, assuming you have added the translations to your model.

For cubes, the Browser tab provides two approaches for exploring data. You can use the built-in MDX Query Designer to build queries that return a flattened rowset from a multidimensional database. Alternatively, you can use an Excel shortcut. When you start Excel from within Visual Studio with Analysis Services projects, Excel opens with a PivotTable already in the worksheet and a predefined connection to the model workspace database.

Excel generally offers a better browsing experience because you can explore cube data interactively, using horizontal and vertical axes to analyze the relationships in your data. In contrast, the MDX Query Designer is limited to a single axis. Moreover, because the rowset is flattened, you do not get the drilldown that an Excel PivotTable provides. As you add more dimensions and hierarchies to your cube, which you will do in subsequent lessons, Excel will be the preferred solution for browsing data.

To browse the deployed cube

1. Switch to **Dimension Designer** for the Product dimension in Visual Studio with Analysis Services projects. To do this, double-click the **Product** dimension in the **Dimensions** node of Solution Explorer.
2. Click the **Browser** tab to display the **All** member of the **Product Key** attribute hierarchy. In lesson three, you will define a user hierarchy for the Product dimension that will let you browse the dimension.
3. Switch to **Cube Designer** in Visual Studio with Analysis Services projects. To do this, double-click the **Analysis Services Tutorial** cube in the **Cubes** node of Solution Explorer.
4. Select the **Browser** tab, and then click the **Reconnect** icon on the toolbar of the designer.

The left pane of the designer shows the objects in the Analysis Services Tutorial cube. On the right side of the **Browser** tab, there are two panes: the upper pane is the **Filter** pane, and the lower pane is the **Data** pane. In an upcoming lesson, you will use the cube browser to do analysis.

[MDX Query Editor \(Analysis Services - Multidimensional Data\)](#)

Lesson 3: Modifying Measures, Attributes and Hierarchies

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After defining your initial cube, you are ready to improve the usefulness and friendliness of the cube. You can do this by adding hierarchies that support navigation and aggregation at various levels, by applying formats to specific measure, and by defining calculations and relationships.

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

This lesson contains the following tasks:

[Modifying Measures](#)

In this task, you specify formatting properties for the currency and percentage measures in the Analysis Services Tutorial cube.

[Modifying the Customer Dimension](#)

In this task, you define a user hierarchy, create named calculations, modify attributes to use named calculations, and group attributes and user hierarchies into display folders.

[Modifying the Product Dimension](#)

In this task, you define a user hierarchy, create named calculations, define the All member name, and define display folders.

[Modifying the Date Dimension](#)

In this task, you define a user hierarchy, modify attribute member names, and use composite keys to specify unique attribute members.

[Browsing the Deployed Cube](#)

In this task, you browse cube data by using the browser in Cube Designer.

[Multidimensional Modeling \(Adventure Works Tutorial\)](#)

Lesson 3-1 - Modifying Measures

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can use the **FormatString** property to define formatting settings that control how measures are displayed to users. In this task, you specify formatting properties for the currency and percentage measures in the Analysis Services Tutorial cube.

To modify the measures of the cube

1. Switch to the **Cube Structure** tab of Cube Designer for the Analysis Services Tutorial cube, expand the **Internet Sales** measure group in the **Measures** pane, right-click **Order Quantity**, and then click **Properties**.
2. In the Properties window, click the **Auto Hide** pushpin icon to pin the Properties window open.

It is easier to change properties for several items in the cube when the Properties window remains open.

3. In the Properties window, click the **FormatString** list, and then type **#,#**.
4. On the toolbar of the **Cube Structure** tab, click the **Show Measures Grid** icon on the left.

The grid view lets you select multiple measures at the same time.

5. Select the following measures. You can select multiple measures by clicking each while holding down the CTRL key:

- **Unit Price**
- **Extended Amount**
- **Discount Amount**
- **Product Standard Cost**
- **Total Product Cost**
- **Sales Amount**
- **Tax Amt**
- **Freight**

6. In the Properties window, in the **FormatString** list, select **Currency**.
7. In the drop-down list at the top of the Properties window (right below the title bar), select the measure **Unit Price Discount Pct**, and then select **Percent** in the **FormatString** list.
8. In the Properties window, change the **Name** property for the **Unit Price Discount Pct** measure to **Unit Price Discount Percentage**.
9. In the **Measures** pane, click **Tax Amt** and change the name of this measure to **Tax Amount**.
10. In the Properties window, click the **Auto Hide** icon to hide the Properties window, and then click **Show Measures Tree** on the toolbar of the **Cube Structure** tab.
11. On the **File** menu, click **Save All**.

Next Task in Lesson

[Modifying the Customer Dimension](#)

See Also

[Define Database Dimensions](#)

[Configure Measure Properties](#)

Lesson 3-2 - Modifying the Customer Dimension

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are many different ways that you can increase the usability and functionality of the dimensions in a cube. In the tasks in this topic, you modify the Customer dimension.

Renaming Attributes

You can change attribute names with the **Dimension Structure** tab of Dimension Designer.

To rename an attribute

1. Switch to **Dimension Designer** for the Customer dimension in Visual Studio with Analysis Services projects. To do this, double-click the **Customer** dimension in the **Dimensions** node of Solution Explorer.
2. In the **Attributes** pane, right-click **English Country Region Name**, and then click **Rename**. Change the name of the attribute to **Country-Region**.
3. Change the names of the following attributes in the same manner:
 - **English Education** attribute - change to **Education**
 - **English Occupation** attribute - change to **Occupation**
 - **State Province Name** attribute - change to **State-Province**
4. On the **File** menu, click **Save All**.

Creating a Hierarchy

You can create a new hierarchy by dragging an attribute from the **Attributes** pane to the **Hierarchies** pane.

To create a hierarchy

1. Drag the **Country-Region** attribute from the **Attributes** pane into the **Hierarchies** pane.
2. Drag the **State-Province** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Country-Region** level.
3. Drag the **City** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **State-Province** level.
4. In the **Hierarchies** pane of the **Dimension Structure** tab, right-click the title bar of the **Hierarchy** hierarchy, select **Rename**, and then type **Customer Geography**.

The name of the hierarchy is now **Customer Geography**.

5. On the **File** menu, click **Save All**.

Adding a Named Calculation

You can add a named calculation, which is a SQL expression that is represented as a calculated column, to a table in a data source view. The expression appears and behaves as a column in the table. Named calculations let you extend the relational schema of existing tables in a data source view without modifying the table in the underlying data source. For more information, see [Define Named Calculations in a Data Source View \(Analysis Services\)](#)

To add a named calculation

1. Open the **Adventure Works DW 2012** data source view by double-clicking it in the **Data Source Views** folder in Solution Explorer.
2. In the **Tables** pane on the left, right-click **Customer**, and then click **New Named Calculation**.
3. In the **Create Named Calculation** dialog box, type **FullName** in the **Column name** box, and then type or copy and paste the following **CASE** statement in the **Expression** box:

```
CASE
WHEN MiddleName IS NULL THEN
    FirstName + ' ' + LastName
ELSE
    FirstName + ' ' + MiddleName + ' ' + LastName
END
```

The **CASE** statement concatenates the **FirstName**, **MiddleName**, and **LastName** columns into a single column that you will use in the Customer dimension as the displayed name for the **Customer** attribute.

4. Click **OK**, and then expand **Customer** in the **Tables** pane.

The **FullName** named calculation appears in the list of columns in the Customer table, with an icon that indicates that it is a named calculation.

5. On the **File** menu, click **Save All**.
6. In the **Tables** pane, right-click **Customer**, and then click **Explore Data**.
7. Review the last column in the **Explore Customer Table** view.

Notice that the **FullName** column appears in the data source view, correctly concatenating data from several columns from the underlying data source and without modifying the original data source.

8. Close the **Explore Customer Table** tab.

Using the Named Calculation for Member Names

After you have created a named calculation in the data source view, you can use the named calculation as a property of an attribute.

To use the named calculation for member names

1. Switch to Dimension Designer for the Customer dimension.
2. In the **Attributes** pane of the **Dimension Structure** tab, click the **Customer Key** attribute.
3. Open the Properties window and click the **Auto Hide** button on the title bar so that it stays open.
4. In the **Name** property field, type **Full Name**.
5. Click in the **NameColumn** property field at the bottom, and then click the browse (...) button to open the **Name Column** dialog box.
6. Select **FullName** at the bottom of the **Source column** list, and then click **OK**.
7. In the Dimensions Structure tab, drag the **Full Name** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **City** level.
8. On the **File** menu, click **Save All**.

Defining Display Folders

You can use display folders to group user and attribute hierarchies into folder structures to increase usability.

To define display folders

1. Open the **Dimension Structure** tab for the Customer dimension.
2. In the **Attributes** pane, select the following attributes by holding down the CTRL key while clicking each of them:
 - **City**
 - **Country-Region**
 - **Postal Code**
 - **State-Province**
3. In the Properties window, click the **AttributeHierarchyDisplayFolder** property field at the top (you might need to point to it to see the full name), and then type **Location**.
4. In the **Hierarchies** pane, click **Customer Geography**, and then in the Properties window on the right, select **Location** as the value of the **DisplayFolder** property.
5. In the **Attributes** pane, select the following attributes by holding down the CTRL key while clicking each of them:
 - **Commute Distance**
 - **Education**
 - **Gender**
 - **House Owner Flag**
 - **Marital Status**
 - **Number Cars Owned**
 - **Number Children At Home**
 - **Occupation**
 - **Total Children**
 - **Yearly Income**
6. In the Properties window, click the **AttributeHierarchyDisplayFolder** property field at the top, and then type **Demographic**.
7. In the **Attributes** pane, select the following attributes by holding down the CTRL key while clicking each of them:
 - **Email Address**
 - **Phone**
8. In the Properties window, click the **AttributeHierarchyDisplayFolder** property field and type **Contacts**.
9. On the **File** menu, click **Save All**.

Defining Composite KeyColumns

The **KeyColumns** property contains the column or columns that represent the key for the attribute. In this lesson, you create a composite key for the **City** and **State-Province** attributes. Composite keys can be helpful when you

need to uniquely identify an attribute. For example, when you define attribute relationships later in this tutorial, a **City** attribute must uniquely identify a **State-Province** attribute. However, there could be several cities with the same name in different states. For this reason, you will create a composite key that is composed of the **StateProvinceName** and **City** columns for the **City** attribute. For more information, see [Modify the KeyColumn Property of an Attribute](#).

To define composite KeyColumns for the City attribute

1. Open the **Dimension Structure** tab for the Customer dimension.
2. In the **Attributes** pane, click the **City** attribute.
3. In the **Properties** window, click in the **KeyColumns** field near the bottom, and then click the browse (...) button.
4. In the **Key Columns** dialog box, in the **Available Columns** list, select the column **StateProvinceName**, and then click the > button.

The **City** and **StateProvinceName** columns are now displayed in the **Key Columns** list.

5. Click **OK**.
6. To set the **NameColumn** property of the **City** attribute, click the **NameColumn** field in the Properties window, and then click the browse (...) button.
7. In the **Name Column** dialog box, in the **Source column** list, select **City**, and then click **OK**.
8. On the **File** menu, click **Save All**.

To define composite KeyColumns for the State-Province attribute

1. Make sure the **Dimension Structure** tab for the Customer dimension is open.
2. In the **Attributes** pane, click the **State-Province** attribute.
3. In the **Properties** window, click in the **KeyColumns** field, and then click the browse (...) button.
4. In the **Key Columns** dialog box, in the **Available Columns** list, select the column **EnglishCountryRegionName**, and then click the > button.

The **EnglishCountryRegionName** and **StateProvinceName** columns are now displayed in the **Key Columns** list.

5. Click **OK**.
6. To set the **NameColumn** property of the **State-Province** attribute, click the **NameColumn** field in the Properties window, and then click the browse (...) button.
7. In the **Name Column** dialog box, in the **Source column** list, select **StateProvinceName**, and then click **OK**.
8. On the **File** menu, click **Save All**.

Defining Attribute Relationships

If the underlying data supports it, you should define attribute relationships between attributes. Defining attribute relationships speeds up dimension, partition, and query processing. For more information, see [Define Attribute Relationships](#) and [Attribute Relationships](#).

To define attribute relationships

1. In the **Dimension Designer** for the Customer dimension, click the **Attribute Relationships** tab. You might need to wait.

2. In the diagram, right-click the **City** attribute, and then click **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **City**. Set the **Related Attribute** to **State-Province**.
4. In the **Relationship type** list, set the relationship type to **Rigid**.

The relationship type is **Rigid** because relationships between the members will not change over time. For example, it would be unusual for a city to become part of a different state or province.

5. Click **OK**.
6. In the diagram, right-click the **State-Province** attribute and then select **New Attribute Relationship**.
7. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **State-Province**. Set the **Related Attribute** to **Country-Region**.
8. In the **Relationship type** list, set the relationship type to **Rigid**.
9. Click **OK**.
10. On the **File** menu, click **Save All**.

Deploying Changes, Processing the Objects, and Viewing the Changes

After you have changed attributes and hierarchies, you must deploy the changes and reprocess the related objects before you can view the changes.

To deploy the changes, process the objects, and view the changes

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. After you receive the **Deployment Completed Successfully** message, click the **Browser** tab of Dimension Designer for the Customer dimension, and then click the Reconnect button on the left side of the toolbar of the designer.
3. Verify that **Customer Geography** is selected in the **Hierarchy** list, and then in the browser pane, expand **All**, expand **Australia**, expand **New South Wales**, and then expand **Coffs Harbour**.

The browser displays the customers in the city.

4. Switch to **Cube Designer** for the Analysis Services Tutorial cube. To do this, double-click the **Analysis Services Tutorial** cube in the **Cubes** node of **Solution Explorer**.
5. Click the **Browser** tab, and then click the Reconnect button on the toolbar of the designer.
6. In the **Measure Group** pane, expand **Customer**.

Notice that instead of a long list of attributes, only the display folders and the attributes that do not have display folder values appear underneath Customer.

7. On the **File** menu, click **Save All**.

Next Task in Lesson

[Modifying the Product Dimension](#)

See Also

[Dimension Attribute Properties Reference](#)

[Remove an Attribute from a Dimension](#)

[Rename an Attribute](#)

[Define Named Calculations in a Data Source View \(Analysis Services\)](#)

Lesson 3-3 - Modifying the Product Dimension

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the tasks in this topic, you use a named calculation to provide more descriptive names for the product lines, define a hierarchy in the Product dimension, and specify the (All) member name for the hierarchy. You also group attributes into display folders.

Adding a Named Calculation

You can add a named calculation to a table in a data source view. In the following task, you create a named calculation that displays the full product line name.

To add a named calculation

1. To open the **Adventure Works DW 2012** data source view, double-click **Adventure Works DW 2012** in the **Data Source Views** folder in Solution Explorer.
2. In the bottom of the diagram pane, right-click the **Product** table header, and then click **New Named Calculation**.
3. In the **Create Named Calculation** dialog box, type **ProductLineName** in the **Column name** box.
4. In the **Expression** box, type or copy and paste the following **CASE** statement:

```
CASE ProductLine
    WHEN 'M' THEN 'Mountain'
    WHEN 'R' THEN 'Road'
    WHEN 'S' THEN 'Accessory'
    WHEN 'T' THEN 'Touring'
    ELSE 'Components'
END
```

This **CASE** statement creates user-friendly names for each product line in the cube.

5. Click **OK** to create the **ProductLineName** named calculation. You might need to wait.
6. On the **File** menu, click **Save All**.

Modifying the NameColumn Property of an Attribute

To modify the NameColumn property value of an attribute

1. Switch to Dimension Designer for the Product dimension. To do this, double-click the **Product** dimension in the **Dimensions** node of Solution Explorer.
2. In the **Attributes** pane of the **Dimension Structure** tab, select **Product Line**.
3. In the Properties window on the right side of the screen, click the **NameColumn** property field at the bottom of the window, and then click the browse (...) button to open the **Name Column** dialog box. (You might need to click the **Properties** tab on the right side of the screen to open the Properties window.)
4. Select **ProductLineName** at the bottom of the **Source column** list, and then click **OK**.

The NameColumn field now contains the text, **Product.ProductLineName (WChar)**. The members of the **Product Line** attribute hierarchy now display the full name of the product line instead of an abbreviated

product line name.

5. In the **Attributes** pane of the **Dimension Structure** tab, select **Product Key**.
6. In the Properties window, click the **NameColumn** property field, and then click the ellipsis browse (...) button to open the **Name Column** dialog box.
7. Select **EnglishProductName** in the **Source column** list, and then click **OK**.

The NameColumn field now contains the text, **Product.EnglishProductName (WChar)**.

8. In the Properties window, scroll up, click the **Name** property field, and then type **Product Name**.

Creating a Hierarchy

To create a hierarchy

1. Drag the **Product Line** attribute from the **Attributes** pane into the **Hierarchies** pane.
2. Drag the **Model Name** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Product Line** level.
3. Drag the **Product Name** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Model Name** level. (You renamed Product Key to Product Name in the previous section.)
4. In the **Hierarchies** pane of the **Dimension Structure** tab, right-click the title bar of the **Hierarchy** hierarchy, click **Rename**, and then type **Product Model Lines**.

The name of the hierarchy is now **Product Model Lines**.

5. On the **File** menu, click **Save All**.

Specifying Folder Names and All Member Names

To specify the folder and member names

1. In the **Attributes** pane, select the following attributes by holding down the CTRL key while clicking each of them:
 - **Class**
 - **Color**
 - **Days To Manufacture**
 - **Reorder Point**
 - **Safety Stock Level**
 - **Size**
 - **Size Range**
 - **Style**
 - **Weight**
2. In the **AttributeHierarchyDisplayFolder** property field in the Properties window, type **Stocking**.

You have now grouped these attributes into a single display folder.

3. In the **Attributes** pane, select the following attributes:
 - **Dealer Price**

- **List Price**
- **Standard Cost**

4. In the **AttributeHierarchyDisplayFolder** property cell in the Properties window, type **Financial**.

You have now grouped these attributes into a second display folder.

5. In the **Attributes** pane, select the following attributes:

- **End Date**
- **Start Date**
- **Status**

6. In the **AttributeHierarchyDisplayFolder** property cell in the Properties window, type **History**.

You have now grouped these attributes into a third display folder.

7. Select the **Product Model Lines** hierarchy in the **Hierarchies** pane, and then change the **AllMemberName** property in the Properties window to **All Products**.

8. Click an open area of the **Hierarchies** pane, and then change the **AttributeAllMemberName** property at the top of the Properties window to **All Products**.

Clicking an open area lets you modify properties of the Product dimension itself. You could also click **Product** at the top of the attributes list in the **Attributes** pane.

9. On the **File** menu, click **Save All**.

Defining Attribute Relationships

If the underlying data supports it, you should define attribute relationships between attributes. Defining attribute relationships speeds up dimension, partition, and query processing. For more information, see [Define Attribute Relationships](#) and [Attribute Relationships](#).

To define attribute relationships

1. In the **Dimension Designer** for the Product dimension, click the **Attribute Relationships** tab.
2. In the diagram, right-click the **Model Name** attribute, and then click **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Model Name**. Set the **Related Attribute** to **Product Line**.

In the **Relationship type** list, leave the relationship type set to **Flexible** because relationships between the members might change over time. For example, a product model might eventually be moved to a different product line.

4. Click **OK**.
5. On the **File** menu, click **Save All**.

Reviewing Product Dimension Changes

To review the Product dimension changes

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. After you have received the **Deployment Completed Successfully** message, click the **Browser** tab of **Dimension Designer** for the **Product** dimension, and then click the Reconnect button on the toolbar of

the designer.

3. Verify that **Product Model Lines** is selected in the **Hierarchy** list, and then expand **All Products**.

Notice that the name of the **All** member appears as **All Products**. This is because you changed the **AllMemberName** property for the hierarchy to **All Products** earlier in the lesson. Also, the members of the **Product Line** level now have user-friendly names, instead of single-letter abbreviations.

Next Task in Lesson

[Modifying the Date Dimension](#)

See Also

[Define Named Calculations in a Data Source View \(Analysis Services\)](#)

[Create User-Defined Hierarchies](#)

[Configure the \(All\) Level for Attribute Hierarchies](#)

Lesson 3-4 - Modifying the Date Dimension

7/16/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the tasks in this topic, you create a user-defined hierarchy and change the member names that are displayed for the Date, Month, Calendar Quarter, and Calendar Semester attributes. You also define composite keys for attributes, control the sort order of dimension members, and define attribute relationships.

Adding a Named Calculation

You can add a named calculation, which is a SQL expression that is represented as a calculated column, to a table in a data source view. The expression appears and behaves as a column in the table. Named calculations enable you to extend the relational schema of existing tables in a data source view without modifying the table in the underlying data source. For more information, see [Define Named Calculations in a Data Source View \(Analysis Services\)](#)

To add a named calculation

1. To open the **Adventure Works DW 2012** data source view, double-click it in the **Data Source Views** folder in Solution Explorer.
2. Near the bottom of the **Tables** pane, right-click **Date**, and then click **New Named Calculation**.
3. In the **Create Named Calculation** dialog box, type **SimpleDate** in the **Column name** box, and then type or copy and paste the following **DATENAME** statement in the **Expression** box:

```
DATENAME(mm, FullDateAlternateKey) + ' ' +
DATENAME(dd, FullDateAlternateKey) + ', ' +
DATENAME(yy, FullDateAlternateKey)
```

The **DATENAME** statement extracts the year, month, and day values from the **FullDateAlternateKey** column. You will use this new column as the displayed name for the **FullDateAlternateKey** attribute.

4. Click **OK**, and then expand **Date** in the **Tables** pane.

The **SimpleDate** named calculation appears in the list of columns in the Date table, with an icon that indicates that it is a named calculation.

5. On the **File** menu, click **Save All**.
6. In the **Tables** pane, right-click **Date**, and then click **Explore Data**.
7. Scroll to the right to review the last column in the **Explore Date Table** view.

Notice that the **SimpleDate** column appears in the data source view, correctly concatenating data from several columns from the underlying data source, without modifying the original data source.

8. Close the **Explore Date Table** view.

Using the Named Calculation for Member Names

After you create a named calculation in the data source view, you can use the named calculation as a property of an attribute.

To use the named calculation for member names

1. Open **Dimension Designer** for the Date dimension in Visual Studio with Analysis Services projects. To do this, double-click the **Date** dimension in the **Dimensions** node of **Solution Explorer**.
2. In the **Attributes** pane of the **Dimension Structure** tab, click the **Date Key** attribute.
3. If the Properties window is not open, open the Properties window, and then click the **Auto Hide** button on the title bar so that it stays open.
4. Click the **NameColumn** property field near the bottom of the window, and then click the ellipsis browse (...) button to open the **Name Column** dialog box.
5. Select **SimpleDate** at the bottom of the **Source column** list, and then click **OK**.
6. On the **File** menu, click **Save All**.

Creating a Hierarchy

You can create a new hierarchy by dragging an attribute from the **Attributes** pane to the **Hierarchies** pane.

To create a hierarchy

1. In **Dimension Structure** tab of the Dimension Designer for the **Date** dimension, drag the **Calendar Year** attribute from the **Attributes** pane into the **Hierarchies** pane.
2. Drag the **Calendar Semester** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Calendar Year** level.
3. Drag the **Calendar Quarter** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Calendar Semester** level.
4. Drag the **English Month Name** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **Calendar Quarter** level.
5. Drag the **Date Key** attribute from the **Attributes** pane into the cell in the **Hierarchies** pane, underneath the **English Month Name** level.
6. In the **Hierarchies** pane, right-click the title bar of the **Hierarchy** hierarchy, click **Rename**, and then type **Calendar Date**.
7. By using the right-click context menu, in the **Calendar Date** hierarchy, rename the **English Month Name** level to **Calendar Month**, and then rename the **Date Key** level to **Date**.
8. Delete the **Full Date Alternate Key** attribute from the **Attributes** pane because you will not be using it. Click **OK** in the **Delete Objects** confirmation window.
9. On the **File** menu, click **Save All**.

Defining Attribute Relationships

If the underlying data supports it, you should define attribute relationships between attributes. Defining attribute relationships speeds up dimension, partition, and query processing.

To define attribute relationships

1. In the **Dimension Designer** for the **Date** dimension, click the **Attribute Relationships** tab.
2. In the diagram, right-click the **English Month Name** attribute, and then click **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **English Month Name**. Set the **Related Attribute** to **Calendar Quarter**.

4. In the **Relationship type** list, set the relationship type to **Rigid**.

The relationship type is **Rigid** because relationships between the members will not change over time.

5. Click **OK**.

6. In the diagram, right-click the **Calendar Quarter** attribute, and then click **New Attribute Relationship**.

7. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Calendar Quarter**. Set the **Related Attribute** to **Calendar Semester**.

8. In the **Relationship type** list, set the relationship type to **Rigid**.

9. Click **OK**.

10. In the diagram, right-click the **Calendar Semester** attribute, and then click **New Attribute Relationship**.

11. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Calendar Semester**. Set the **Related Attribute** to **Calendar Year**.

12. In the **Relationship type** list, set the relationship type to **Rigid**.

13. Click **OK**.

14. On the **File** menu, click **Save All**.

Providing Unique Dimension Member Names

In this task, you will create user-friendly name columns that will be used by the **EnglishMonthName**, **CalendarQuarter**, and **CalendarSemester** attributes.

To provide unique dimension member names

1. To switch to the **Adventure Works DW 2012** data source view, double-click it in the **Data Source Views** folder in Solution Explorer.

2. In the **Tables** pane, right-click **Date**, and then click **New Named Calculation**.

3. In the **Create Named Calculation** dialog box, type **MonthName** in the **Column name** box, and then type or copy and paste the following statement in the **Expression** box:

```
EnglishMonthName + ' ' + CONVERT(CHAR (4), CalendarYear)
```

The statement concatenates the month and year for each month in the table into a new column.

4. Click **OK**.

5. In the **Tables** pane, right-click **Date**, and then click **New Named Calculation**.

6. In the **Create Named Calculation** dialog box, type **CalendarQuarterDesc** in the **Column name** box, and then type or copy and paste the following SQL script in the **Expression** box:

```
'Q' + CONVERT(CHAR (1), CalendarQuarter) + ' ' + 'CY ' +
CONVERT(CHAR (4), CalendarYear)
```

This SQL script concatenates the calendar quarter and year for each quarter in the table into a new column.

7. Click **OK**.

8. In the **Tables** pane, right-click **Date**, and then click **New Named Calculation**.

9. In the **Create Named Calculation** dialog box, type **CalendarSemesterDesc** in the **Column name** box, and then type or copy and paste the following SQL script in the **Expression** box:

```
CASE
WHEN CalendarSemester = 1 THEN 'H1' + ' ' + 'CY' + ''
    + CONVERT(CHAR(4), CalendarYear)
ELSE
'H2' + ' ' + 'CY' + '' + CONVERT(CHAR(4), CalendarYear)
END
```

This SQL script concatenates the calendar semester and year for each semester in the table into a new column.

10. Click **OK**.

11. On the **File** menu, click **Save All**.

Defining Composite KeyColumns and Setting the Name Column

The **KeyColumns** property contains the column or columns that represent the key for the attribute. In this task, you will define composite **KeyColumns**.

To define composite KeyColumns for the English Month Name attribute

1. Open the **Dimension Structure** tab for the Date dimension.
2. In the **Attributes** pane, click the **English Month Name** attribute.
3. In the **Properties** window, click the **KeyColumns** field, and then click the browse (...) button.
4. In the **Key Columns** dialog box, in the **Available Columns** list, select the column **CalendarYear**, and then click the > button.
5. The **EnglishMonthName** and **CalendarYear** columns are now displayed in the **Key Columns** list.
6. Click **OK**.
7. To set the **NameColumn** property of the **EnglishMonthName** attribute, click the **NameColumn** field in the Properties window, and then click the browse (...) button.
8. In the **Name Column** dialog box, in the **Source Column** list, select **MonthName**, and then click **OK**.
9. On the **File** menu, click **Save All**.

To define composite KeyColumns for the Calendar Quarter attribute

1. In the **Attributes** pane, click the **Calendar Quarter** attribute.
2. In the **Properties** window, click the **KeyColumns** field, and then click the browse (...) button.
3. In the **Key Columns** dialog box, in the **Available Columns** list, select the column **CalendarYear**, and then click the > button.

The **CalendarQuarter** and **CalendarYear** columns are now displayed in the **Key Columns** list.

4. Click **OK**.
5. To set the **NameColumn** property of the **Calendar Quarter** attribute, click the **NameColumn** field in the Properties window, and then click the browse (...) button.
6. In the **Name Column** dialog box, in the **Source Column** list, select **CalendarQuarterDesc**, and then click **OK**.

7. On the **File** menu, click **Save All**.

To define composite KeyColumns for the Calendar Semester attribute

1. In the **Attributes** pane, click the **Calendar Semester** attribute.
2. In the **Properties** window, click the **KeyColumns** field, and then click the browse (...) button.
3. In the **Key Columns** dialog box, in the **Available Columns** list, select the column, **CalendarYear**, and then click the > button.

The **CalendarSemester** and **CalendarYear** columns are now displayed in the **Key Columns** list.

4. Click **OK**.
5. To set the **NameColumn** property of the **Calendar Semester** attribute, click the **NameColumn** field in the property window, and then click the browse (...) button.
6. In the **Name Column** dialog box, in the **Source Column** list, select **CalendarSemesterDesc**, and then click **OK**.
7. On the **File** menu, click **Save All**.

Deploying and Viewing the Changes

After you have changed attributes and hierarchies, you must deploy the changes and reprocess the related objects before you can view the changes.

To deploy and view the changes

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. After you have received the **Deployment Completed Successfully** message, click the **Browser** tab of **Dimension Designer** for the **Date** dimension, and then click the Reconnect button on the toolbar of the designer.
3. Select **Calendar Quarter** from the **Hierarchy** list. Review the members in the **Calendar Quarter** attribute hierarchy.

Notice that the names of the members of the **Calendar Quarter** attribute hierarchy are clearer and easier to use because you created a named calculation to use as the name. Members now exist in the **Calendar Quarter** attribute hierarchy for each quarter in each year. The members are not sorted in chronological order. Instead they are sorted by quarter and then by year. In the next task in this topic, you will modify this behavior to sort the members of this attribute hierarchy by year and then by quarter.

4. Review the members of the **English Month Name** and **Calendar Semester** attribute hierarchies.

Notice that the members of these hierarchies are also not sorted in chronological order. Instead, they are sorted by month or semester, respectively, and then by year. In the next task in this topic, you will modify this behavior to change this sort order.

Changing the Sort Order by Modifying Composite Key Member Order

In this task, you will change the sort order by changing the order of the keys that make up the composite key.

To modify the composite key member order

1. Open the **Dimension Structure** tab of Dimension Designer for the **Date** dimension, and then select **Calendar Semester** in the **Attributes** pane.
2. In the Properties window, review the value for the **OrderBy** property. It is set to **Key**.

The members of the **Calendar Semester** attribute hierarchy are sorted by their key value. With a composite key, the ordering of the member keys is based first on the value of the first member key, and then on the value of the second member key. In other words, the members of the **Calendar Semester** attribute hierarchy are sorted first by semester and then by year.

3. In the Properties window, click the ellipsis browse button (...) to change the **KeyColumns** property value.
4. In the **Key Columns** list of the **Key Columns** dialog box, verify that **CalendarSemester** is selected, and then click the down arrow to reverse the order of the members of this composite key. Click **OK**.

The members of the attribute hierarchy are now sorted first by year and then by semester.

5. Select **Calendar Quarter** in the **Attributes** pane, and then click the ellipsis browse button (...) for the **KeyColumns** property in the Properties window.
6. In the **Key Columns** list of the **Key Columns** dialog box, verify that **CalendarQuarter** is selected, and then click the down arrow to reverse the order of the members of this composite key. Click **OK**.

The members of the attribute hierarchy are now sorted first by year and then by quarter.

7. Select **English Month Name** in the **Attributes** pane, and then click the ellipsis button (...) for the **KeyColumns** property in the Properties window.
8. In the **Key Columns** list of the **Key Columns** dialog box, verify that **EnglishMonthName** is selected, and then click the down arrow to reverse the order of the members of this composite key. Click **OK**.

The members of the attribute hierarchy are now sorted first by year and then by month.

9. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**. When deployment has successfully completed, click the **Browser** tab in Dimension Designer for the **Date** dimension.
10. On the toolbar of the **Browser** tab, click the Reconnect button.

11. Review the members of the **Calendar Quarter** and **Calendar Semester** attribute hierarchies.

Notice that the members of these hierarchies are now sorted in chronological order, by year and then by quarter or semester, respectively.

12. Review the members of the **English Month Name** attribute hierarchy.

Notice that the members of the hierarchy are now sorted first by year and then alphabetically by month. This is because the data type for the EnglishCalendarMonth column in the data source view is a string column, based on the nvarchar data type in the underlying relational database. For information about how to enable the months to be sorted chronologically within each year, see [Sorting Attribute Members Based on a Secondary Attribute](#).

Next Task in Lesson

[Browsing the Deployed Cube](#)

[Dimensions in Multidimensional Models](#)

Lesson 3-5 - Browsing the Deployed Cube

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the following task, you browse the Analysis Services Tutorial cube. Because our analysis compares measure across multiple dimensions, you will use an Excel PivotTable to browse your data. Using a PivotTable lets you place customer, date, and product information on different axes so that you can see how Internet Sales change when viewed across specific time periods, customer demographics, and product lines.

To browse the deployed cube

1. To switch to Cube Designer in Visual Studio with Analysis Services projects, double-click the **Analysis Services Tutorial** cube in the **Cubes** folder of the Solution Explorer.
2. Open the **Browser** tab, and then click the **Reconnect** button on the toolbar of the designer.
3. Click the Excel icon to launch Excel using the workspace database as the data source. When prompted to enable connections, click **Enable**.
4. In the PivotTable Field List, expand **Internet Sales**, and then drag the **Sales Amount** measure to the **Values** area.
5. In the PivotTable Field List, expand **Product**.
6. Drag the **Product Model Lines** user hierarchy to the **Columns** area.
7. In the PivotTable Field List, expand **Customer**, expand **Location**, and then drag the **Customer Geography** hierarchy from the Location display folder in the Customer dimension to the **Rows** area.
8. In the PivotTable Field List, expand **Order Date**, and then drag the **Order Date.Calendar Date** hierarchy to the **Report Filter** area.
9. Click the arrow to the right of the **Order Date.Calendar Date** filter in the data pane, clear the check box for the **(All)** level, expand **2006**, expand **H1 CY 2006**, expand **Q1 CY 2006**, select the check box for **February 2006**, and then click **OK**.

Internet sales by region and product line for the month of February, 2006 appear as shown in the following image.

Lesson 4: Defining Advanced Attribute and Dimension Properties

Lesson 4: Defining Advanced Attribute and Dimension Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In this lesson, you will learn how to use some of the advanced properties of attributes, attribute hierarchies, and dimension properties.

NOTE

This lesson is based on an enhanced version of the Analysis Services Tutorial project that you completed in the first three lessons of this tutorial. The first task in this lesson describes where to locate the appropriate sample project to use for the lesson, and the difference between this project and the project that you created in the first three lessons.

This lesson contains the following tasks:

[Using a Modified Version of the Analysis Services Tutorial Project](#)

In this task, you open, review, and deploy a modified version of the Analysis Services Tutorial project, which has multiple measure groups and additional dimensions.

[Defining Parent Attribute Properties in a Parent-Child Hierarchy](#)

In this task, you define level names in a parent-child dimension and specify whether data related to parent members is displayed. For more information, see [Parent-Child Dimensions](#) and [Attributes in Parent-Child Hierarchies](#).

[Automatically Grouping Attribute Members](#)

In this task, you automatically create groupings of attribute members based on the distribution of the members within the attribute hierarchy. For more information, see [Group Attribute Members \(Discretization\)](#).

[Hiding and Disabling Attribute Hierarchies](#)

In this task, you learn how and when to disable or hide attribute hierarchies.

[Sorting Attribute Members Based on a Secondary Attribute](#)

In this task, you learn how to sort dimension members based on a secondary attribute, to achieve the sort order that you want.

[Specifying Attribute Relationships Between Attributes in a User-Defined Hierarchy](#)

In this task, you learn how to define member properties for attributes and to specify aggregation relationships between them. For more information, see [Define Attribute Relationships](#) and [User Hierarchy Properties](#).

[Defining the Unknown Member and Null Processing Properties](#)

In this task, you configure the UnknownMember and UnknownMemberName properties to handle error conditions caused by null dimension members.

Analysis Services Tutorial Scenario

Dimensions in Multidimensional Models

Lesson 4-1 – Using a Modified Version of the Analysis Services Tutorial Project

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

The remaining lessons in this tutorial are based on an enhanced version of the Analysis Services Tutorial project that you completed in the first three lessons. Additional tables and named calculations have been added to the **Adventure Works DW 2012** data source view, additional dimensions have been added to the project, and these new dimensions have been added to the Analysis Services Tutorial cube. In addition, a second measure group has been added, which contains measures from a second fact table. This enhanced project will enable you to continue learning how to add functionality to your business intelligence application without having to repeat the skills you have already learned.

Before you can continue with the tutorial, you must download, extract, load and process the enhanced version of the Analysis Services Tutorial project. Use the instructions in this lesson to ensure you have performed all the steps.

Downloading and Extracting the Project File

1. [Click here](#) to go to the download page that provides the sample projects that go with this tutorial. The tutorial projects are included in the **adventure-works-multidimensional-tutorial-projects.zip** download.
2. Click **adventure-works-multidimensional-tutorial-projects.zip** to download the package that contains the projects for this tutorial.

By default, a .zip file is saved to the Downloads folder. You must move the .zip file to a location that has a shorter path (for example, create a C:\Tutorials folder to store the files). You can then extract the files contained in the .zip file. If you attempt to unzip the files from the Downloads folder, which has a longer path, you will only get Lesson 1.

3. Create a subfolder at or near the root drive, for example, C:\Tutorial.
4. Move the **adventure-works-multidimensional-tutorial-projects.zip** file to the subfolder.
5. Right-click the file and select **Extract All**.
6. Browse to the **Lesson 4 Start** folder to find the **Analysis Services Tutorial.sln** file.

Loading and Processing the Enhanced Project

1. In Visual Studio with Analysis Services projects, on the **File** menu, click **Close Solution** to close files you won't be using.
2. On the **File** menu, point to **Open**, and then click **Project/Solution**.
3. Browse to the location where you extracted the tutorial project files.

Find the folder named **Lesson 4 Start**, and then double-click **Analysis Services Tutorial.sln**.

4. Deploy the enhanced version of the Analysis Services Tutorial project to the local instance of Analysis Services, or to another instance, and verify that processing completes successfully.

Understanding the Enhancements to the Project

The enhanced version of the project is different from the version of the Analysis Services Tutorial project that you completed in the first three lessons. The differences are described in the following sections. Review this information before continuing with the remaining lessons in the tutorial.

Data Source View

The data source view in the enhanced project contains one additional fact table and four additional dimension tables from the **AdventureWorksDW2012** database.

Notice that with ten tables in the data source view, the diagram is becoming crowded. This makes it difficult to easily understand the relationships between the tables and to locate specific tables. To solve this problem, the tables are organized into two logical diagrams, the **Internet Sales** diagram and the **Reseller Sales** diagram. These diagrams are each organized around a single fact table. Creating logical diagrams lets you view and work with a specific subset of the tables in a data source view instead of always viewing all the tables and their relationships in a single diagram.

Internet Sales Diagram

The **Internet Sales** diagram contains the tables that are related to the sale of Adventure Works products directly to customers through the Internet. The tables in the diagram are the four dimension tables and one fact table that you added to the **Adventure Works DW 2012** data source view in Lesson 1. These tables are as follows:

- **Geography**
- **Customer**
- **Date**
- **Product**
- **InternetSales**

Reseller Sales Diagram

The **Reseller Sales** diagram contains the tables that are related to the sale of Adventure Works products by resellers. This diagram contains the following seven dimension tables and one fact table from the

AdventureWorksDW2012 database:

- **Reseller**
- **Promotion**
- **SalesTerritory**
- **Geography**
- **Date**
- **Product**
- **Employee**
- **ResellerSales**

Notice that the **DimGeography**, **DimDate**, and **DimProduct** tables are used in both the **Internet Sales** diagram and the **Reseller Sales** diagram. Dimension tables can be linked to multiple fact tables.

Database and Cube Dimensions

The Analysis Services Tutorial project contains five new database dimensions, and the Analysis Services Tutorial cube contains these same five dimensions as cube dimensions. These dimensions have been defined to have user hierarchies and attributes that were modified by using named calculations, composition member keys, and display

folders. The new dimensions are described in the following list.

Reseller Dimension

The Reseller dimension is based on the **Reseller** table in the **Adventure Works DW 2012** data source view.

Promotion Dimension

The Promotion dimension is based on the **Promotion** table in the **Adventure Works DW 2012** data source view.

Sales Territory Dimension

The Sales Territory dimension is based on the **SalesTerritory** table in the **Adventure Works DW 2012** data source view.

Employee Dimension

The Employee dimension is based on the **Employee** table in the **Adventure Works DW 2012** data source view.

Geography Dimension

The Geography dimension is based on the **Geography** table in the **Adventure Works DW 2012** data source view.

Analysis Services Cube

The **Analysis Services Tutorial** cube now contains two measure groups, the original measure group based on the **InternetSales** table and a second measure group based on the **ResellerSales** table in the **Adventure Works DW 2012** data source view.

Next Task in Lesson

[Defining Parent Attribute Properties in a Parent-Child Hierarchy](#)

See Also

[Deploying an Analysis Services Project](#)

Lesson 4-2 - Defining Parent Attribute Properties in a Parent-Child Hierarchy

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A parent-child hierarchy is a hierarchy in a dimension that is based on two table columns. Together, these columns define the hierarchical relationships among the members of the dimension. The first column, called the *member key column*, identifies each dimension member. The other column, called the *parent column*, identifies the parent of each dimension member. The **NamingTemplate** property of a parent attribute determines the name of each level in the parent-child hierarchy, and the **MembersWithData** property determines whether data for parent members should be displayed.

For more information, see [Parent-Child Dimensions, Attributes in Parent-Child Hierarchies](#)

NOTE

When you use the Dimension Wizard to create a dimension, the wizard recognizes the tables that have parent-child relationships and automatically defines the parent-child hierarchy for you.

In the tasks in this topic, you will create a naming template that defines the name for each level in the parent-child hierarchy in the **Employee** dimension. You will then configure the parent attribute to hide all parent data, so that only the sales for leaf-level members are displayed.

Browsing the Employee Dimension

1. In Solution Explorer, double-click **Employee.dim** in the **Dimensions** folder to open Dimension Designer for the Employee dimension.
2. Click the **Browser** tab, verify that **Employees** is selected in the **Hierarchy** list, and then expand the **All Employees** member.

Notice that **Ken J. Sánchez** is the top-level manager in this parent-child hierarchy.

3. Select the **Ken J. Sánchez** member.

Notice that the level name for this member is **Level 02**. (The level name appears after **Current level**: immediately above the **All Employees** member.) In the next task, you will define more descriptive names for each level.

4. Expand **Ken J. Sánchez** to view the names of the employees who report to this manager, and then select **Brian S. Welcker** to view the name of this level.

Notice that the level name for this member is **Level 03**.

5. In Solution Explorer, double-click **Analysis Services Tutorial.cube** in the **Cubes** folder to open Cube Designer for the Analysis Services Tutorial cube.
6. Click the **Browser** tab.
7. Click the Excel icon, and then click **Enable** when prompted to enable connections.
8. In the PivotTable Field List, expand **Reseller Sales**. Drag **Reseller Sales-Sales Amount** to the Values area.

9. In the PivotTable Field List, expand **Employee**, and then drag the **Employees** hierarchy to the **Rows** area.

All the members of the Employees hierarchy are added to column A of the PivotTable report.

The following image shows the Employees hierarchy expanded.

A screenshot of Microsoft Excel showing a PivotTable report. The PivotTable Field List pane on the right shows the 'Employees' hierarchy under the 'Employee' attribute. The main table shows sales data for various employees, with the 'Employees' hierarchy expanded to show sales for each manager's subordinates.

| | A | B |
|---------------------------|-----------------------------|-----------------|
| 1 Row Labels | Reseller Sales-Sales Amount | |
| 2 Ken J. Sánchez | | \$80,450,596.98 |
| 3 Brian S. Welcker | | \$80,450,596.98 |
| 4 Brian S. Welcker | Stephen Y. Jiang | \$63,320,315.35 |
| 5 Brian S. Welcker | Stephen Y. Jiang | \$1,092,123.86 |
| 6 Michael G. blythe | | \$9,293,903.01 |
| 7 Linda C. Mitchell | | \$10,367,007.43 |
| 8 Jillian Carson | | \$10,065,403.54 |
| 9 Garrett R. Vargas | | \$3,609,447.22 |
| 10 Tsvi Micahel. Reiter | | \$7,171,012.75 |
| 11 Pamela O. Anzman-Wolfe | | \$3,325,102.60 |
| 12 Shu K. Ito | | \$6,427,005.56 |
| 13 José Edvaldo. Saraiva | | \$5,926,418.36 |
| 14 David r. Cambell | | \$3,729,945.35 |
| 15 Tete A. Mensa-Annan | | \$2,312,545.69 |
| 16 Amy E. Alberts | | \$15,535,946.26 |
| 17 Syed E. Abbas | | \$1,594,335.38 |
| 18 Grand Total | | \$80,450,596.98 |
| 19 | | |

10.

Notice that the sales made by each manager in Level 03 are also displayed in Level 04. This is because each manager is also an employee of another manager. In the next task, you will hide these sale amounts.

Modifying Parent Attribute Properties in the Employee Dimension

1. Switch to Dimension Designer for the **Employee** dimension.

2. Click the **Dimension Structure** tab, and then select the **Employees** attribute hierarchy in the **Attributes** pane.

Notice the unique icon for this attribute. This icon signifies that the attribute is the parent key in a parent-child hierarchy. Notice also, in the Properties window, that the **Usage** property for the attribute is defined as **Parent**. This property was set by the Dimension Wizard when the dimension was designed. The wizard automatically detected the parent-child relationship.

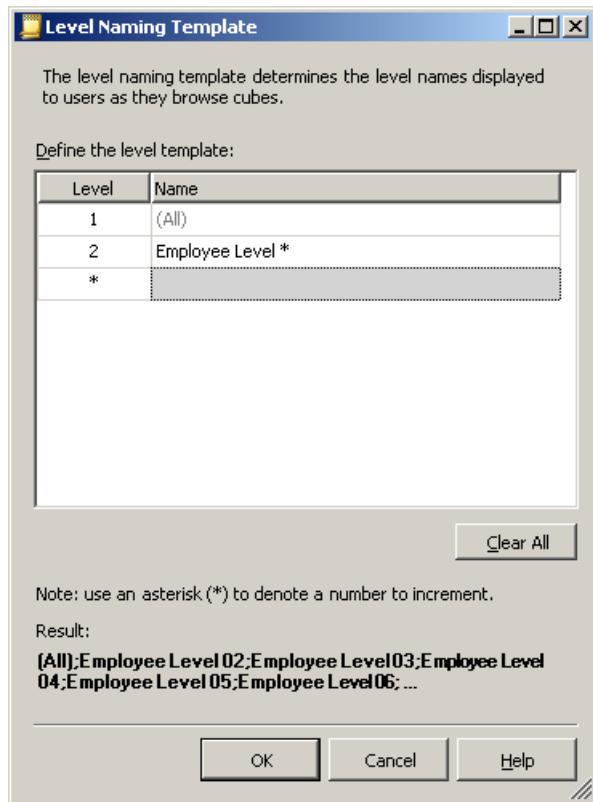

3. In the Properties window, click the ellipsis button (...) in the **NamingTemplate** property cell.

In the **Level Naming Template** dialog box, you define the level naming template that determines the level names in the parent-child hierarchy that are displayed to users as they browse cubes.

4. In the second row, the * row, type **Employee Level *** in the **Name** column, and then click the third row.

Notice under **Result** that each level will now be named "Employee Level" followed by a sequentially increasing number.

The following image shows the changes in the **Level Naming Template** dialog box.

5. Click **OK**.
6. In the Properties window for the **Employees** attribute, in the **MembersWithData** property cell, select **NonLeafDataHidden** to change this value for the **Employees** attribute.

This will cause data that is related to non-leaf level members in the parent-child hierarchy to be hidden.

Browsing the Employee Dimension with the Modified Attributes

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to Cube Designer for the Analysis Services Tutorial cube, and then click **Reconnect** on the toolbar of the **Browser** tab.
3. Click the Excel icon, and then click **Enable**.
4. Drag **Reseller Sales-Sales Amount** to the Values area.
5. Drag the **Employees** hierarchy to the Row Labels area.

The following image shows the changes that you made to the Employees hierarchy. Notice that Stephen Y. Jiang no longer appears as an employee of himself.

The screenshot shows a Microsoft Excel window with the title "Book2 - Microsoft Excel". The ribbon at the top has tabs for File, Home, Insert, Page Layout, Formulas, Data, Review, and View. The "PivotTable Tools" tab is currently selected, indicated by a pink background. The "Design" tab is also visible. The main area contains a PivotTable with data from the "Employees" dimension. The PivotTable Field List pane on the right shows fields related to "Employees", including Employee Department, Contact Information, Demographic, History, Organization, and More fields. The PivotTable itself has "Row Labels" set to "Employees" and "Values" set to "Reseller Sales-Sales Amount". The data shows sales amounts for various employees, with a grand total of \$80,450,596.98.

| | A | B |
|----|------------------------|-----------------------------|
| 1 | Row Labels | Reseller Sales-Sales Amount |
| 2 | Ken J. Sánchez | \$80,450,596.98 |
| 3 | Brian S. Welcker | \$80,450,596.98 |
| 4 | Stephen Y. Jiang | \$63,320,315.35 |
| 5 | Michael G. Blythe | \$9,293,903.01 |
| 6 | Linda C. Mitchell | \$10,367,007.43 |
| 7 | Jillian Carson | \$10,065,803.54 |
| 8 | Garrett R. Vargas | \$3,609,447.22 |
| 9 | Tsvi Michael. Reiter | \$7,171,012.75 |
| 10 | Pamela O. Anzman-Wolfe | \$3,325,102.60 |
| 11 | Shu K. Ito | \$6,427,005.56 |
| 12 | José Edvaldo. Saraiva | \$5,926,418.36 |
| 13 | David R. Campbell | \$3,729,945.35 |
| 14 | Tete A. Mensa-Annan | \$2,312,545.69 |
| 15 | Amy E. Alberts | \$15,535,946.26 |
| 16 | Syed E. Abbas | \$1,594,335.38 |
| 17 | Grand Total | \$80,450,596.98 |
| 18 | | |
| 19 | | |

[Automatically Grouping Attribute Members](#)

See Also

[Parent-Child Dimensions](#)

[Attributes in Parent-Child Hierarchies](#)

Lesson 4-3 - Automatically Grouping Attribute Members

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you browse a cube, you typically dimension the members of one attribute hierarchy by the members of another attribute hierarchy. For example, you might group customer sales by city, by product purchased, or by gender. However, with certain types of attributes, it is useful to have Microsoft Analysis Services automatically create groupings of attribute members based on the distribution of the members within an attribute hierarchy. For example, you can have Analysis Services create groups of yearly income values for customers. When you do this, users who browse the attribute hierarchy will see the names and values of the groups instead of the members themselves. This limits the number of levels that are presented to users, which can be more useful for analysis.

The **DiscretizationMethod** property determines whether Analysis Services creates groupings, and determines the type of grouping that is performed. By default, Analysis Services does not perform any groupings. When you enable automatic groupings, you can allow Analysis Services to automatically determine the best grouping method based on the structure of the attribute, or you can choose one of the grouping algorithms in the following list to specify the grouping method:

EqualAreas

Analysis Services creates group ranges so that the total population of dimension members is distributed equally across the groups.

Clusters

Analysis Services creates groups by performing single-dimensional clustering on the input values by using the K-Means clustering method with Gaussian distributions. This option is valid only for numeric columns.

After you specify a grouping method, you must specify the number of groups, by using the **DiscretizationBucketCount** property. For more information, see [Group Attribute Members \(Discretization\)](#)

In the tasks in this topic, you will enable different types of groupings for the following: the yearly income values in the **Customer** dimension; the number of employee sick leave hours in the **Employees** dimension; and the number of employee vacation hours in the **Employees** dimension. You will then process and browse the Analysis Services Tutorial cube to view the effect of the member groups. Finally, you will modify the member group properties to see the effect of the change in grouping type.

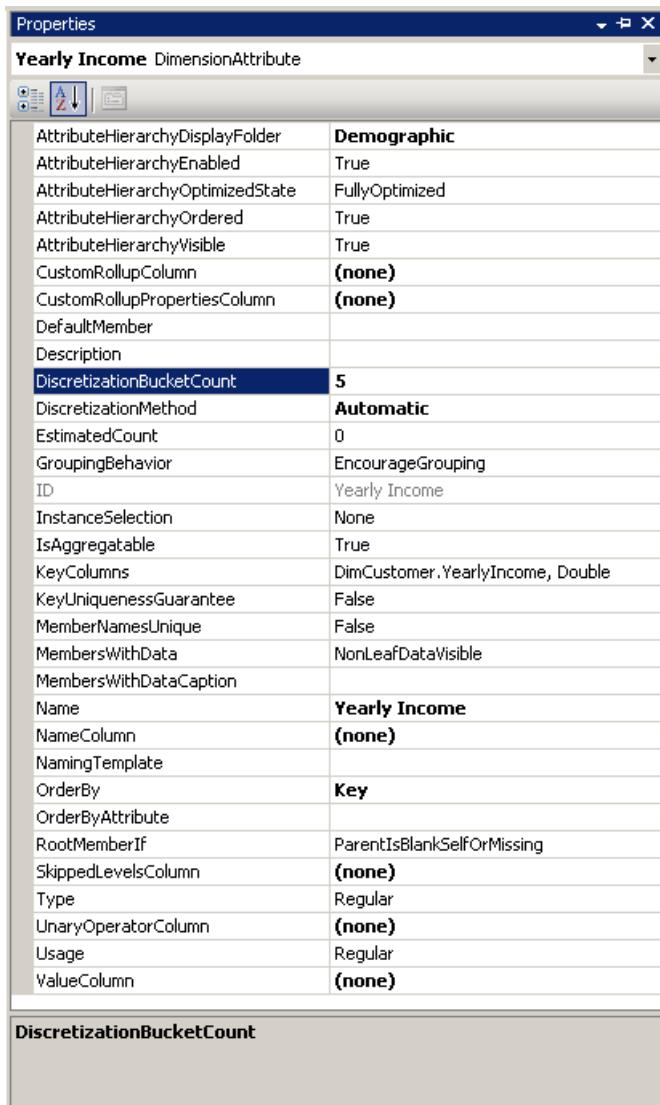

Grouping Attribute Hierarchy Members in the Customer Dimension

1. In Solution Explorer, double-click **Customer** in the **Dimensions** folder to open Dimension Designer for the Customer dimension.
2. In the **Data Source View** pane, right-click the **Customer** table, and then click **Explore Data**.

Notice the range of values for the **YearlyIncome** column. These values become the members of the **Yearly Income** attribute hierarchy, unless you enable member grouping.

3. Close the **Explore Customer Table** tab.
4. In the **Attributes** pane, select **Yearly Income**.
5. In the Properties window, change the value for the **DiscretizationMethod** property to **Automatic** and change the value for the **DiscretizationBucketCount** property to **5**.

The following image shows the modified properties for **Yearly Income**.

Grouping Attribute Hierarchy Members in the Employee Dimension

1. Switch to Dimension Designer for the Employee dimension.
2. In the **Data Source View** pane, right-click the **Employee** table, and then click **Explore Data**.
Notice the values for the **SickLeaveHours** column and the **VacationHours** column.
3. Close the **Explore Employee Table** tab.
4. In the **Attributes** pane, select **Sick Leave Hours**.
5. In the Properties window, change the value for the **DiscretizationMethod** property to **Clusters** and change the value for the **DiscretizationBucketCount** property to **5**.
6. In the **Attributes** pane, select **Vacation Hours**.
7. In the Properties window, change the value for the **DiscretizationMethod** property to **Equal Areas** and change the value for the **DiscretizationBucketCount** property to **5**.

Browsing the Modified Attribute Hierarchies

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.

2. When deployment has successfully completed, switch to Cube Designer for the Analysis Services Tutorial cube, and then click **Reconnect** on the **Browser** tab.
3. Click the Excel icon, and then click **Enable**.
4. Drag the **Internet Sales-Sales Amount** measure to the Values area of the PivotTable Field List.
5. In the field list, expand the **Product** dimension, and then drag the **Product Model Lines** user hierarchy to the **Row Labels** area of the field list.
6. Expand the **Customer** dimension in the field list, expand the **Demographic** display folder, and then drag the **Yearly Income** attribute hierarchy to the **Column Labels** area.

The members of the **Yearly Income** attribute hierarchy are now grouped into six buckets, including a bucket for sales to customers whose yearly income is unknown. Not all buckets are displayed.

7. Remove the **Yearly Income** attribute hierarchy from the columns area and remove the **Internet Sales-Sales Amount** measure from the **Values** area.
8. Add the **Reseller Sales-Sales Amount** measure to the data area.
9. In the field list, expand the **Employee** dimension, expand **Organization**, then drag **Sick Leave Hours** to **Column Labels**.

Notice that all sales are made by employees within one of two groups. Notice also that the employees with 32 - 42 sick leave hours made significantly more sales than employees with 20 - 31 sick leave hours.

The following image shows sales dimensioned by employee sick leave hours.

The screenshot shows a Microsoft Excel window with a PivotTable. The PivotTable has 'Reseller Sales-Sales Amount' in the Column Labels area, 'Row Labels' with categories like Components, Mountain, Road, Accessory, and Touring, and 'Grand Total' for each category. The PivotTable Tools ribbon tab is selected, showing the 'Design' tab. The 'PivotTable Field List' pane is open, showing the 'Show fields related to' section with 'Sick Leave Hours' checked. The 'Drag fields between areas below' section shows 'Report Filter' with 'Sick Leave Hours' selected, and 'Column Labels' with 'Sick Leave Hours' also selected. The Data pane shows 'Product Mode...' and 'Reseller Sales...'. The status bar at the bottom indicates 'Ready' and '100%'. The PivotTable data is as follows:

| | 20 - 30 | 31 - 40 | Grand Total |
|--------------------|-----------------------|------------------------|------------------------|
| Components | \$22,699.05 | \$517,549.75 | \$540,248.80 |
| Mountain | \$639,043.06 | \$31,566,504.97 | \$32,205,548.04 |
| Road | \$681,466.96 | \$32,956,479.62 | \$33,637,946.58 |
| Accessory | \$62,641.86 | \$1,872,706.43 | \$1,935,348.29 |
| Touring | \$590,875.82 | \$11,540,629.46 | \$12,131,505.28 |
| Grand Total | \$1,996,726.75 | \$78,453,870.23 | \$80,450,596.98 |

10. Remove the **Sick Leave Hours** attribute hierarchy from the column area of the **Data** pane.
11. Add **Vacation Hours** to the column area of the **Data** pane.

Notice that two groups appear, based on the equal areas grouping method. Three other groups are hidden

because they contain no data values.

Modifying Grouping Properties and Reviewing the Effect of the Changes

1. Switch to Dimension Designer for the **Employee** dimension, and then select **Vacation Hours** in the **Attributes** pane.
2. In the Properties window, change the value of the **DiscretizationBucketCount** property to **10**.
3. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
4. When deployment has successfully completed, switch back to Cube Designer for the Analysis Services Tutorial cube.
5. Click **Reconnect** on the **Browser** tab, click the Excel icon, and then reconstruct the PivotTable so that you can view the effect of the change to the grouping method:
 - a. Drag Reseller Sales-Sales Amount to Values
 - b. Drag Vacation Hours (in the Employees Organization folder) to Columns
 - c. Drag Product Model Lines to Rows

Notice that there are now three groups of members of the **Vacation Hours** attribute that have sales values for products. (The other seven groups contain members with no sales data.)

Next Task in Lesson

[Hiding and Disabling Attribute Hierarchies](#)

See Also

[Group Attribute Members \(Discretization\)](#)

Lesson 4-4 - Hiding and Disabling Attribute Hierarchies

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

By default, an attribute hierarchy is created for every attribute in a dimension, and each hierarchy is available for dimensioning fact data. This hierarchy consists of an "All" level and a detail level containing all members of the hierarchy. As you have already learned, you can organize attributes into user-defined hierarchies to provide navigation paths in a cube. Under certain circumstances, you may want to disable or hide some attributes and their hierarchies. For example, certain attributes such as social security numbers or national identification numbers, pay rates, birth dates, and login information are not attributes by which users will dimension cube information. Instead, this information is generally only viewed as details of a particular attribute member. You may want to hide these attribute hierarchies, leaving the attributes visible only as member properties of a specific attribute. You may also want to make members of other attributes, such as customer names or postal codes, visible only when they are viewed through a user hierarchy instead of independently through an attribute hierarchy. One reason to do so may be the sheer number of distinct members in the attribute hierarchy. Finally, to improve processing performance, you should disable attribute hierarchies that users will not use for browsing.

The value of the **AttributeHierarchyEnabled** property determines whether an attribute hierarchy is created. If this property is set to **False**, the attribute hierarchy is not created and the attribute cannot be used as a level in a user hierarchy; the attribute hierarchy exists as a member property only. However, a disabled attribute hierarchy can still be used to order the members of another attribute. If the value of the **AttributeHierarchyEnabled** property is set to **True**, the value of the **AttributeHierarchyVisible** property determines whether the attribute hierarchy is visible independent of its use in a user-defined hierarchy.

When an attribute hierarchy is enabled, you may want to specify values for the following three additional properties:

- **IsAggregatable**

By default, an (All) level is defined for all attribute hierarchies. To disable the (All) level for an enabled attribute hierarchy, set the value for this property to **False**.

NOTE

An attribute that has its **IsAggregatable** property set to false can only be used as the root of a user-defined hierarchy and must have a default member specified (otherwise, one will be chosen for you by the Analysis Services engine).

- **AttributeHierarchyOrdered**

By default, Analysis Services orders the members of enabled attribute hierarchies during processing, and then stores the members by the value of the **OrderBy** property, such as by Name or Key. If you do not care about ordering, you can increase processing performance by setting the value of this property to **False**.

- **AttributeHierarchyOptimizedState**

By default, Analysis Services creates an index for each enabled attribute hierarchy during processing, to improve query performance. If you do not plan to use an attribute hierarchy for browsing, you can increase processing performance by setting the value of this property to **NotOptimized**. However, if you use a

hidden hierarchy as the key attribute for the dimension, creating an index of the attribute members will still improve performance.

These properties do not apply if an attribute hierarchy is disabled.

In the tasks in this topic, you will disable social security numbers and other attributes in the Employee dimension that will not be used for browsing. You will then hide the customer name and postal code attribute hierarchies in the Customer dimension. The large number of attribute members in these hierarchies will make browsing these hierarchies very slow independent of a user hierarchy.

Setting Attribute Hierarchy Properties in the Employee Dimension

1. Switch to Dimension Designer for the Employee dimension, and then click the **Browser** tab.

2. Verify that the following attribute hierarchies appear in the **Hierarchy** list:

- **Base Rate**
- **Birth Date**
- **Login ID**
- **Manager SSN**
- **SSN**

3. Switch to the **Dimension Structure** tab, and then select the following attributes in the **Attributes** pane.

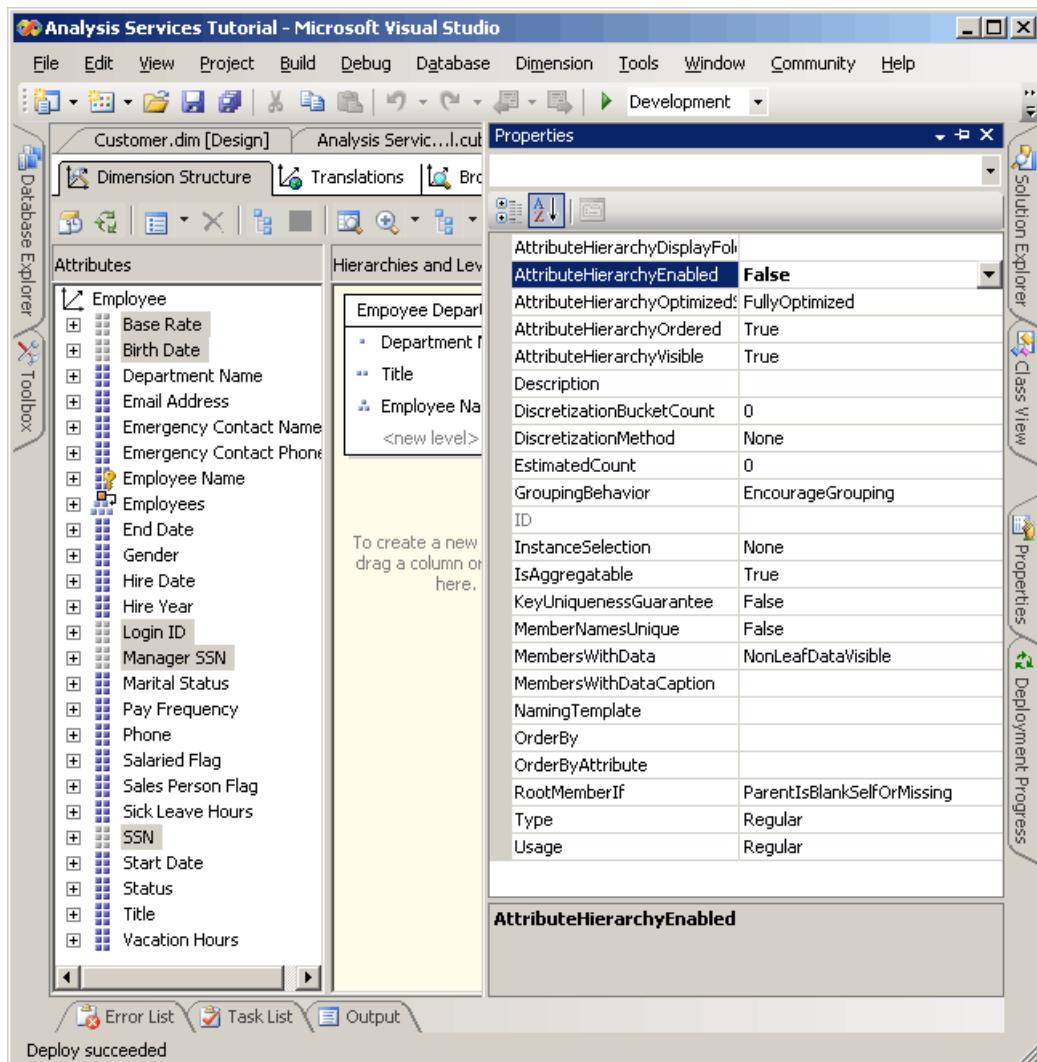

You can select multiple measures by clicking each while holding down the CTRL key:

- **Base Rate**
- **Birth Date**
- **Login ID**
- **Manager SSN**
- **SSN**

4. In the Properties window, set the value of the **AttributeHierarchyEnabled** property to **False** for the selected attributes.

Notice in the **Attributes** pane that the icon for each attribute has changed to indicate that the attribute is not enabled.

The following image shows the **AttributeHierarchyEnabled** property set to False for the selected attributes.

5. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
6. When processing has successfully completed, switch to the **Browser** tab, click **Reconnect**, and then try to browse the modified attribute hierarchies.

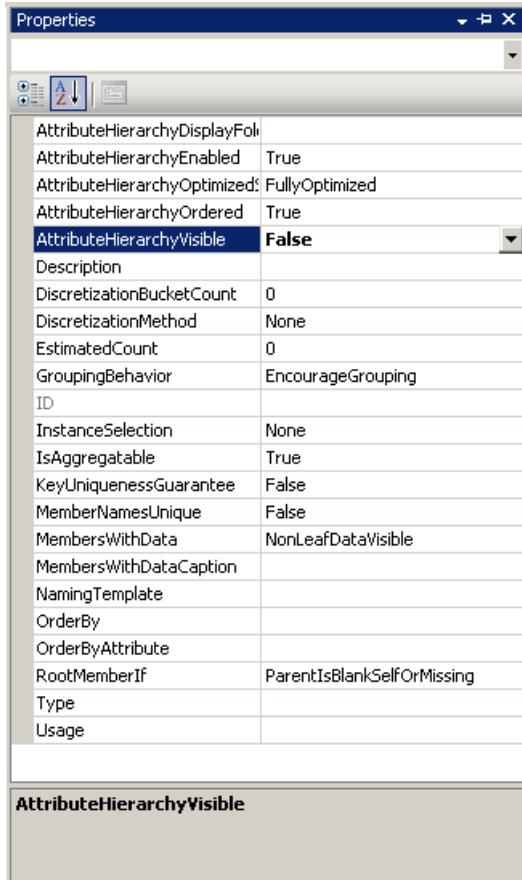

Notice that the members of the modified attributes are not available for browsing as attribute hierarchies in the **Hierarchy** list. If you try to add one of the disabled attribute hierarchies as a level in a user hierarchy, you will receive an error notifying you that the attribute hierarchy must be enabled to participate in a user-defined hierarchy.

Setting Attribute Hierarchy Properties in the Customer Dimension

1. Switch to Dimension Designer for the Customer dimension, and then click the **Browser** tab.
2. Verify that the following attribute hierarchies appear in the **Hierarchy** list:
 - **Full Name**
 - **Postal Code**
3. Switch to the **Dimension Structure** tab, and then select the following attributes in the **Attributes** pane by using the CTRL key to select multiple attributes at the same time:
 - **Full Name**
 - **Postal Code**
4. In the Properties window, set the value of the **AttributeHierarchyVisible** property to **False** for the selected attributes.

Because the members of these attribute hierarchies will be used for dimensioning fact data, ordering and optimizing the members of these attribute hierarchies will improve performance. Therefore, the properties of these attributes should not be changed.

The following image shows the **AttributeHierarchyVisible** property set to False.

5. Drag the **Postal Code** attribute from the **Attributes** pane into the **Customer Geography** user hierarchy in the **Hierarchies and Levels** pane, immediately under the **City** level.

Notice that a hidden attribute can still become a level in a user hierarchy.

6. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
7. When deployment has successfully completed, switch to the **Browser** tab for the Customer dimension, and then click **Reconnect**.

8. Try to select either of the modified attribute hierarchies from the **Hierarchy** list.

Notice that neither of the modified attribute hierarchies appears in the **Hierarchy** list.

9. In the **Hierarchy** list, select **Customer Geography**, and then browse each level in the browser pane.

Notice that the hidden levels, **Postal Code** and **Full Name**, are visible in the user-defined hierarchy.

Next Task in Lesson

[Sorting Attribute Members Based on a Secondary Attribute](#)

Lesson 4-5 - Sorting Attribute Members Based on a Secondary Attribute

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Lesson 3, you learned how to sort attribute members based on either their name or key value. You also learned how to use a composite member key to affect attribute members and sort order. For more information, see [Modifying the Date Dimension](#). However, if neither the name nor the key of the attribute provide the sort order that you want, you can use a secondary attribute to achieve the desired sort order. By defining a relationship between the attributes, you can use the second attribute to sort the members of the first attribute.

Attribute relationships define the relationships or dependencies between attributes. In a dimension that is based on a single relational table, all attributes are typically related to each other through the key attribute. This is because all the attributes for a dimension provide information about the members linked by the key attribute of the dimension to the facts in the fact table for each related measure group. In a dimension that is based on multiple tables, attributes are typically linked based on the join key between the tables. If the underlying data supports it, related attributes can be used to specify a sort order. For example, you might create a new attribute that provides the sort logic for a related attribute.

Dimension Designer lets you define additional relationships between attributes or change the default relationships to increase performance. The main constraint when you create an attribute relationship is to make sure that the attribute referred to has no more than one value for any member in the attribute to which it is related. When you define a relationship between two attributes, you can define the relationship as rigid or flexible, based on whether the relationships between members will change over time. For example, an employee might move to a different sales region, but a city will not move to a different state. If a relationship is defined as rigid, attribute aggregations are not recalculated every time the dimension is incrementally processed. However, if the relationship between members does change, the dimension must be fully processed. For more information, see [Attribute Relationships](#), [Define Attribute Relationships](#), [Configure Attribute Relationship Properties](#), and [Specifying Attribute Relationships Between Attributes in a User-Defined Hierarchy](#).

In the tasks in this topic, you will define a new attribute in the **Date** dimension based on an existing column in the underlying dimension table. You will use this new attribute to sort calendar month members chronologically instead of alphabetically. You will also define a new attribute in the **Customer** dimension based on the named calculation that you will use to sort the **Commute Distance** attribute members. In the tasks in the next topic, you will learn to use attribute relationships to increase query performance.

Defining an Attribute Relationship and Sort Order in the Date Dimension

1. Open Dimension Designer for the **Date** dimension, and then review the **OrderBy** property for the **Month Name** attribute in the Properties window.

Notice that the **Month Name** attribute members are ordered by their key values.

2. Switch to the **Browser** tab, verify that **Calendar Date** is selected in the **Hierarchy** list, and then expand the levels in the user-defined hierarchy to review the sort order for the calendar months.

Notice that the members of the attribute hierarchy are sorted based on the ASCII values of their member keys, which are month and year. In this case, sorting by the attribute name or key does not sort calendar months chronologically. To solve this, you will sort the members of the attribute hierarchy based on a new

attribute, the **MonthNumberOfYear** attribute. You will create this attribute based on a column that conveniently exists in the **Date** dimension table.

3. Switch to the **Dimension Structure** tab for the Date dimension, right-click **MonthNumberOfYear** in the **Data Source View** pane, and then click **New Attribute from Column**.
4. In the **Attributes** pane, select **Month Number Of Year**, and then set the **AttributeHierarchyEnabled** property to **False** in the Properties window, set the **AttributeHierarchyOptimizedState** property to **NotOptimized**, and set the **AttributeHierarchyOrdered** property to **False**.

These settings will hide the attribute from users and will improve processing time. This attribute will not be used for browsing. It will only be used for ordering the members of another attribute.

NOTE

Sorting properties in the Properties window alphabetically will simplify this task as these three properties will be sorted adjacent to each other.

5. Click the **Attribute Relationships** tab.

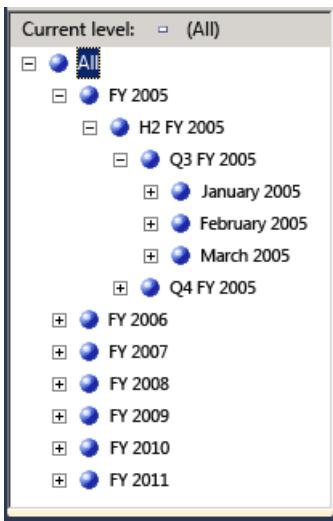

Notice that all the attributes in the **Date** dimension are related directly to the **Date** attribute, which is the member key that relates the dimension members to the facts in the related measure groups. There is no relationship defined between the **Month Name** attribute and the **Month Number Of Year** attribute.

6. In the diagram, right-click the **Month Name** attribute and then select **New Attribute Relationship**.
7. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Month Name**. Set the **Related Attribute** to **Month Number Of Year**.
8. In the **Relationship type** list, set the relationship type to **Rigid**.

The relationships between the members of the **Month Name** attribute and the **Month Number Of Year** attribute will not change over time. As a result, Analysis Services will not drop aggregations for this relationship during incremental processing. If a change does occur, a processing error will occur during incremental processing and you will need to perform a full process of the dimension. You are now ready to set the sort order for the members of **Month Name**.

9. Click **OK**.
10. Click the **Dimension Structure** tab.
11. Select **Month Name** in the **Attributes** pane, and then change the value of the **OrderBy** property in the Properties window to **AttributeKey** and change the value of the **OrderByAttribute** property to **Month Number Of Year**.
12. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
13. When deployment has successfully completed, switch to the **Browser** tab for the Date dimension, click **Reconnect**, and then browse the **Calendar Date** and **Fiscal Date** user hierarchies to verify that months now sort in chronological order.

Notice that the months are now sorted in chronological order, as shown in the following image.

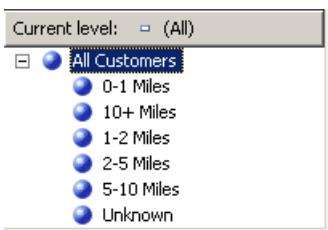

Defining Attribute Relationships and Sort Order in the Customer Dimension

1. Switch to the **Browser** tab in Dimension Designer for the Customer dimension, and then browse the members of the **Commute Distance** attribute hierarchy.

Notice that the members of this attribute hierarchy are sorted based on the ASCII values of the member key. In this case, sorting by the attribute name or key does not sort the commute distances from least to most. In this task, you sort the members of the attribute hierarchy based on the **CommuteDistanceSort** named calculation that ascribes the appropriate sort number to each distinct value in the column. To save time, this named calculation has already been added to the **Customer** table in the Adventure Works DW data source view. You can switch to this data source view to view the SQL script that is used in this named calculation. For more information, see [Define Named Calculations in a Data Source View \(Analysis Services\)](#).

The following image shows the members of the **Commute Distance** attribute hierarchy, sorted by the ASCII values of the member key.

2. Switch to the **Dimension Structure** tab in Dimension Designer for the Customer dimension, right-click **CommuteDistanceSort** in the **Customer** table in the **Data Source View** pane, and then click **New Attribute from Column**.
3. In the **Attributes** pane, select **Commute Distance Sort**, and then set the **AttributeHierarchyEnabled** property for this attribute to **False** in the Properties window, set the **AttributeHierarchyOptimizedState** property to **NotOptimized**, and set the **AttributeHierarchyOrdered** property to **False**.

These settings will hide the attribute from users and will improve processing time. This attribute will not be used for browsing. It will only be used for ordering the members of another attribute.

4. Select **Geography**, and then set its **AttributeHierarchyVisible** property to **False** in the Properties window, set its **AttributeHierarchyOptimizedState** property to **NotOptimized**, and set its **AttributeHierarchyOrdered** property to **False**.

These settings will hide the attribute from users and will improve processing time. This attribute will not be

used for browsing. It will be only be used for ordering the members of another attribute. Because **Geography** has member properties, its **AttributeHierarchyEnabled** property must be set to **True**. Therefore, to hide the attribute, you set the **AttributeHierarchyVisible** property to **False**.

5. Click the **Attribute Relationships** tab.
6. In the attributes list, right-click the **Commute Distance** attribute and then select **New Attribute Relationship**.
7. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Commute Distance**. Set the **Related Attribute** to **Commute Distance Sort**.
8. In the **Relationship type** list, set the relationship type to **Rigid**.

The relationship between the members of the **Commute Distance** attribute and the **Commute Distance Sort** attribute will not change over time.

9. Click **OK**.

You are now ready to set the sort order for the **Commute Distance** attribute.

10. Click the **Dimension Structure** tab.
11. In the **Attributes** pane, select **Commute Distance**, and then change the value of the **OrderBy** property in the Properties window to **AttributeKey**, and change the value of the **OrderByAttribute** property to **Commute Distance Sort**.
12. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
13. When deployment has successfully completed, switch to the **Browser** tab of Dimension Designer for the Customer dimension, click **Reconnect**, and then browse the **Commute Distance** attribute hierarchy.

Notice that the attribute hierarchy members are now sorted in a logical order based on increasing distance, as shown in the following image.

Next Task in Lesson

[Specifying Attribute Relationships Between Attributes in a User-Defined Hierarchy](#)

4-6-Specifying Attribute Relationships in User-Defined Hierarchy

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

As you have already learned in this tutorial, you can organize attribute hierarchies into levels within user hierarchies to provide navigation paths for users in a cube. A user hierarchy can represent a natural hierarchy, such as city, state, and country, or can just represent a navigation path, such as employee name, title, and department name. To the user navigating a hierarchy, these two types of user hierarchies are the same.

With a natural hierarchy, if you define attribute relationships between the attributes that make up the levels, Analysis Services can use an aggregation from one attribute to obtain the results from a related attribute. If there are no defined relationships between attributes, Analysis Services will aggregate all non-key attributes from the key attribute. Therefore, if the underlying data supports it, you should define attribute relationships between attributes. Defining attribute relationships improves dimension, partition, and query processing performance. For more information, see [Define Attribute Relationships](#) and [Attribute Relationships](#).

When you define attribute relationships, you can specify that the relationship is either flexible or rigid. If you define a relationship as rigid, Analysis Services retains aggregations when the dimension is updated. If a relationship that is defined as rigid actually changes, Analysis Services generates an error during processing unless the dimension is fully processed. Specifying the appropriate relationships and relationship properties increases query and processing performance. For more information, see [Define Attribute Relationships](#), and [User Hierarchy Properties](#).

In the tasks in this topic, you define attribute relationships for the attributes in the natural user hierarchies in the Analysis Services Tutorial project. These include the **Customer Geography** hierarchy in the **Customer** dimension, the **Sales Territory** hierarchy in the **Sales Territory** dimension, the **Product Model Lines** hierarchy in the **Product** dimension, and the **Fiscal Date** and **Calendar Date** hierarchies in the **Date** dimension. These user hierarchies are all natural hierarchies.

Defining Attribute Relationships for Attributes in the Customer Geography Hierarchy

1. Switch to Dimension Designer for the Customer dimension, and then click the **Dimension Structure** tab.

In the **Hierarchies** pane, notice the levels in the **Customer Geography** user-defined hierarchy. This hierarchy is currently just a drill-down path for users, as no relationship between levels or attributes have been defined.

2. Click the **Attribute Relationships** tab.

Notice the four attribute relationships that link the non-key attributes from the **Geography** table to the key attribute from the **Geography** table. The **Geography** attribute is related to the **Full Name** attribute. The **Postal Code** attribute is indirectly linked to the **Full Name** attribute through the **Geography** attribute, because the **Postal Code** is linked to the **Geography** attribute and the **Geography** attribute is linked to the **Full Name** attribute. Next, we will change the attribute relationships so that they do not use the **Geography** attribute.

3. In the diagram, right-click the **Full Name** attribute and then select **New Attribute Relationship**.

4. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Full Name**. Set the **Related Attribute** to **Postal Code**. In the **Relationship type** list, leave the relationship type set to **Flexible** because relationships between the members might change over time.
 5. Click **OK**.
- A warning icon appears in the diagram because the relationship is redundant. The relationship **Full Name -> Geography-> Postal Code** already existed, and you just created the relationship **Full Name -> Postal Code**. The relationship **Geography-> Postal Code** is now redundant, so we will remove it.
6. In the **Attribute Relationships** pane, right-click **Geography-> Postal Code** and then click **Delete**.
 7. When the **Delete Objects** dialog box appears, click **OK**.
 8. In the diagram, right-click the **Postal Code** attribute and then select **New Attribute Relationship**.
 9. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Postal Code**. Set the **Related Attribute** to **City**. In the **Relationship type** list, leave the relationship type set to **Flexible**.
 10. Click **OK**.

The relationship **Geography-> City** is now redundant so we will delete it.

11. In the Attribute Relationships pane, right-click **Geography-> City** and then click **Delete**.
 12. When the **Delete Objects** dialog box appears, click **OK**.
 13. In the diagram, right-click the **City** attribute and then select **New Attribute Relationship**.
 14. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **City**. Set the **Related Attribute** to **State-Province**. In the **Relationship type** list, set the relationship type to **Rigid** because the relationship between a city and a state will not change over time.
 15. Click **OK**.
 16. Right-click the arrow between **Geography** and **State-Province** and then click **Delete**.
 17. When the **Delete Objects** dialog box appears, click **OK**.
 18. In the diagram, right-click the **State-Province** attribute and then select **New Attribute Relationship**.
 19. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **State-Province**. Set the **Related Attribute** to **Country-Region**. In the **Relationship type** list, set the relationship type to **Rigid** because the relationship between a state-province and a country-region will not change over time.
 20. Click **OK**.
 21. In the Attribute Relationships pane, right-click **Geography-> Country-Region** and then click **Delete**.
 22. When the **Delete Objects** dialog box appears, click **OK**.
 23. Click the **Dimension Structure** tab.
- Notice that when you delete the last attribute relationship between **Geography** and other attributes, that **Geography** itself is deleted. This is because the attribute is no longer used.
24. On the File menu, click **Save All**.

Defining Attribute Relationships for Attributes in the Sales Territory Hierarchy

1. Open Dimension Designer for the **Sales Territory** dimension, and then click the **Attribute Relationships**

tab.

2. In the diagram, right-click the **Sales Territory Country** attribute and then select **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Sales Territory Country**. Set the **Related Attribute** to **Sales Territory Group**. In the **Relationship type** list, leave the relationship type set to **Flexible**.
4. Click **OK**.

Sales Territory Group is now linked to **Sales Territory Country**, and **Sales Territory Country** is now linked to **Sales Territory Region**. The **RelationshipType** property for each of these relationships is set to **Flexible** because the groupings of regions within a country might change over time and because the groupings of countries into groups might change over time.

Defining Attribute Relationships for Attributes in the Product Model Lines Hierarchy

1. Open Dimension Designer for the **Product** dimension, and then click the **Attribute Relationships** tab.
2. In the diagram, right-click the **Model Name** attribute and then select **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Model Name**. Set the **Related Attribute** to **Product Line**. In the **Relationship type** list, leave the relationship type set to **Flexible**.
4. Click **OK**.

Defining Attribute Relationships for Attributes in the Fiscal Date Hierarchy

1. Switch to Dimension Designer for the **Date** dimension, and then click the **Attribute Relationships** tab.
2. In the diagram, right-click the **Month Name** attribute and then select **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Month Name**. Set the **Related Attribute** to **Fiscal Quarter**. In the **Relationship type** list, set the relationship type to **Rigid**.
4. Click **OK**.
5. In the diagram, right-click the **Fiscal Quarter** attribute and then select **New Attribute Relationship**.
6. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Fiscal Quarter**. Set the **Related Attribute** to **Fiscal Semester**. In the **Relationship type** list, set the relationship type to **Rigid**.
7. Click **OK**.
8. In the diagram, right-click the **Fiscal Semester** attribute and then select **New Attribute Relationship**.
9. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Fiscal Semester**. Set the **Related Attribute** to **Fiscal Year**. In the **Relationship type** list, set the relationship type to **Rigid**.
10. Click **OK**.

Defining Attribute Relationships for Attributes in the Calendar Date Hierarchy

1. In the diagram, right-click the **Month Name** attribute and then select **New Attribute Relationship**.

2. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Month Name**. Set the **Related Attribute** to **Calendar Quarter**. In the **Relationship type** list, set the relationship type to **Rigid**.
3. Click **OK**.
4. In the diagram, right-click the **Calendar Quarter** attribute and then select **New Attribute Relationship**.
5. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Calendar Quarter**. Set the **Related Attribute** to **Calendar Semester**. In the **Relationship type** list, set the relationship type to **Rigid**.
6. Click **OK**.
7. In the diagram, right-click the **Calendar Semester** attribute and then select **New Attribute Relationship**.
8. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Calendar Semester**. Set the **Related Attribute** to **Calendar Year**. In the **Relationship type** list, set the relationship type to **Rigid**.
9. Click **OK**.

Defining Attribute Relationships for Attributes in the Geography Hierarchy

1. Open Dimension Designer for the Geography dimension, and then click the **Attribute Relationships** tab.
2. In the diagram, right-click the **Postal Code** attribute and then select **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Postal Code**. Set the **Related Attribute** to **City**. In the **Relationship type** list, set the relationship type to **Flexible**.
4. Click **OK**.
5. In the diagram, right-click the **City** attribute and then select **New Attribute Relationship**.
6. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **City**. Set the **Related Attribute** to **State-Province**. In the **Relationship type** list, set the relationship type to **Rigid**.
7. Click **OK**.
8. In the diagram, right-click the **State-Province** attribute and then select **New Attribute Relationship**.
9. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **State-Province**. Set the **Related Attribute** to **Country-Region**. In the **Relationship type** list, set the relationship type to **Rigid**.
10. Click **OK**.
11. In the diagram, right-click the **Geography Key** attribute and then select **Properties**.
12. Set the **AttributeHierarchyOptimizedState** property to **NotOptimized**, set the **AttributeHierarchyOrdered** property to **False**, and set the **AttributeHierarchyVisible** property to **False**.
13. On the **File** menu, click **Save All**.
14. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.

Lesson 4-7 - Defining the Unknown Member and Null Processing Properties

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When Analysis Services processes a dimension, all the distinct values from the underlying columns in the tables, or views in the data source view, populate the attributes in the dimension. If Analysis Services encounters a null value during processing, by default, it converts this null to a zero for numeric columns or to an empty string for string columns. You can modify the default settings or convert null values in your extract, transform, and load process (if any) of the underlying relational data warehouse. Additionally, you can have Analysis Services convert the null value to a designated value by configuring three properties: the **UnknownMember** and **UnknownMemberName** properties for the dimension, and the **NullProcessing** property for the dimension's key attribute.

The Dimension Wizard and the Cube Wizard will enable these properties for you based on whether the key attribute of a dimension is nullable or the root attribute of a snowflake dimension is based on a nullable column. In these cases, the **NullProcessing** property of the key attribute will be set to **UnknownMember** and the **UnknownMember** property will be set to **Visible**.

However, when you build snowflaked dimensions incrementally, as we are doing with the Product dimension in this tutorial, or when you define dimensions using Dimension Designer and then incorporate these existing dimensions into a cube, the **UnknownMember** and **NullProcessing** properties might need to be set manually.

In the tasks in this topic, you will add the product category and product subcategory attributes to the Product dimension from snowflaked tables that you will add to the Adventure Works DW data source view. You will then enable the **UnknownMember** property for the Product dimension, specify **Assembly Components** as the value for the **UnknownMemberName** property, relate the **Subcategory** and **Category** attributes to the product name attribute, and then define custom error handling for the member key attribute that links the snowflaked tables.

NOTE

If you have added the Subcategory and Category attributes when you originally defined the Analysis Services Tutorial cube using the Cube Wizard, these steps would have been performed for you automatically.

Reviewing Error Handling and Unknown Member Properties in the Product Dimension

1. Switch to Dimension Designer for the **Product** dimension, click the **Dimension Structure** tab, and then select **Product** in the **Attributes** pane.

This enables you to view and modify the properties of the dimension itself.

2. In the Properties window, review the **UnknownMember** and **UnknownMemberName** properties.

Notice that the **UnknownMember** property is not enabled, because its value is set to **None** instead of **Visible** or **Hidden**, and that no name is specified for the **UnknownMemberName** property.

3. In the Properties window, select **(custom)** in the **ErrorConfiguration** property cell, and then expand the **ErrorConfiguration** properties collection.

Setting the **ErrorConfiguration** property to **(custom)** allows you to view the default error configuration settings - it does not change any settings.

4. Review the key and null key error configuration properties, but do not make any changes.

Notice that, by default, when null keys are converted to the unknown member and the processing error associated with this conversion is ignored.

The following image shows the property settings for the **ErrorConfiguration** properties collection.

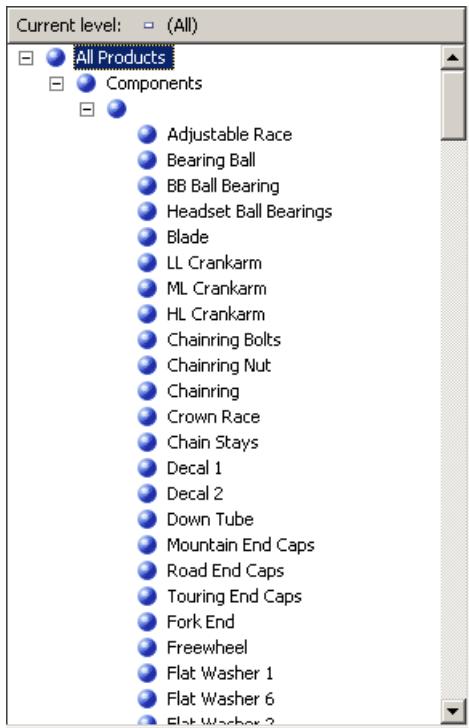

| ErrorConfiguration | (custom) |
|---------------------------|-------------------|
| KeyDuplicate | IgnoreError |
| KeyErrorAction | ConvertToUnknown |
| KeyErrorLimit | 0 |
| KeyErrorLimitAction | StopProcessing |
| KeyErrorLogFile | |
| KeyNotFound | ReportAndContinue |
| NullKeyConvertedToUnknown | IgnoreError |
| NullKeyNotAllowed | ReportAndContinue |

5. Click the **Browser** tab, verify that **Product Model Lines** is selected in the **Hierarchy** list, and then expand **All Products**.

Notice the five members of the Product Line level.

6. Expand **Components**, and then expand the unlabeled member of the **Model Name** level.

This level contains the assembly components that are used when building other components, starting with the **Adjustable Race** product, as shown in the following image.

Defining Attributes from Snowflaked Tables and a Product Category User-Defined Hierarchy

1. Open Data Source View Designer for the Adventure Works DW data source view, select **Reseller Sales** in the **Diagram Organizer** pane, and then click **Add/Remove Objects** on the **Data Source View** menu of Visual Studio with Analysis Services projects.

The **Add/Remove Tables** dialog box opens.

2. In the **Included objects** list, select **DimProduct (dbo)**, and then click **Add Related Tables**.

Both **DimProductSubcategory (dbo)** and **FactProductInventory (dbo)** are added. Remove **FactProductInventory (dbo)** so that just the **DimProductSubcategory (dbo)** table is added to the **Included objects** list.

3. With the **DimProductSubcategory (dbo)** table selected by default as the table most recently added, click **Add Related Tables** again.

The **DimProductCategory (dbo)** table is added to the **Included objects** list.

4. Click **OK**.
5. On the **Format** menu of Visual Studio with Analysis Services projects, point to **Auto Layout**, and then click **Diagram**.

Notice that the **DimProductSubcategory (dbo)** table and **DimProductCategory (dbo)** table are linked to each other, and also to the **ResellerSales** table through the **Product** table.

6. Switch to Dimension Designer for the **Product** dimension, and then click the **Dimension Structure** tab.
7. Right-click anywhere in the **Data Source View** pane, and then click **Show All Tables**.
8. In the **Data Source View** pane, locate the **DimProductCategory** table, right-click **ProductCategoryKey** in that table, and then click **New Attribute from Column**.
9. In the **Attributes** pane, change the name of this new attribute to **Category**.
10. In the Properties window, click in the **NameColumn** property field and then click the browse (...) button to open the **Name Column** dialog box.
11. Select **EnglishProductName** in the **Source column** list and then click **OK**.
12. In the **Data Source View** pane, locate the **DimProductSubcategory** table, right-click **ProductSubcategoryKey** in that table, and then click **New Attribute from Column**.
13. In the **Attributes** pane, change the name of this new attribute to **Subcategory**.
14. In the Properties window, click in the **NameColumn** property field and then click the browse (...) button to open the **Name Column** dialog box.
15. Select **EnglishProductSubcategoryName** in the **Source column** list and then click **OK**.
16. Create a new user-defined hierarchy called **Product Categories** with the following levels, in order from top to bottom: **Category**, **Subcategory**, and **Product Name**.
17. Specify **All Products** as the value for the **AllMemberName** property of the Product Categories user-defined hierarchy.

Browsing the User-Defined Hierarchies in the Product Dimension

1. On the toolbar of the **Dimension Structure** tab of **Dimension Designer** for the **Product** dimension, click **Process**.
2. Click **Yes** to build and deploy the project, and then click **Run** to process the **Product** dimension.
3. When processing has succeeded, expand **Processing Dimension 'Product' completed successfully** in the **Process Progress** dialog box, expand **Processing Dimension Attribute 'Product Name' completed**, and then expand **SQL queries 1**.
4. Click the **SELECT DISTINCT** query and then click **View Details**.

Notice that a WHERE clause has been added to the **SELECT DISTINCT** clause that removes those products

that have no value in the ProductSubcategoryKey column, as shown in the following image.

5. Click **Close** three times to close all processing dialog boxes.
6. Click the **Browser** tab in Dimension Designer for the **Product** dimension, and then click **Reconnect**.
7. Verify that **Product Model Lines** appears in the **Hierarchy** list, expand **All Products**, and then expand **Components**.
8. Select **Product Categories** in the **Hierarchy** list, expand **All Products**, and then expand **Components**.

Notice that none of the assembly components appear.

To modify the behavior mentioned in the previous task, you will enable the **UnknownMember** property of the Products dimension, set a value for the **UnknownMemberName** property, set the **NullProcessing** property for the **Subcategory** and **Model Name** attributes to **UnknownMember**, define the **Category** attribute as a related attribute of the **Subcategory** attribute, and then define the **Product Line** attribute as a related attribute of the **Model Name** attribute. These steps will cause Analysis Services to use the unknown member name value for each product that does not have a value for the **SubcategoryKey** column, as you will see in the following task.

Enabling the Unknown Member, Defining Attribute Relationships, and Specifying Custom Processing Properties for Nulls

1. Click the **Dimension Structure** tab in Dimension Designer for the **Product** dimension, and then select **Product** in the **Attributes** pane.
2. In the **Properties** window, change the **UnknownMember** property to **Visible**, and then change the value for the **UnknownMemberName** property to **Assembly Components**.

Changing the **UnknownMember** property to either **Visible** or **Hidden** enables the **UnknownMember** property for the dimension.

3. Click the **Attribute Relationships** tab.
4. In the diagram, right-click the **Subcategory** attribute and then select **New Attribute Relationship**.
5. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Subcategory**. Set the **Related Attribute** to **Category**. Leave the relationship type set to **Flexible**.
6. Click **OK**.
7. In the **Attributes** pane, select **Subcategory**.
8. In the Properties window, expand the **KeyColumns** property and then expand the **DimProductSubcategory.ProductSubcategoryKey (Integer)** property.
9. Change the **NullProcessing** property to **UnknownMember**.
10. In the **Attributes** pane, select **Model Name**.
11. In the Properties window, expand the **KeyColumns** property and then expand the **Product.ModelName (WChar)** property.
12. Change the **NullProcessing** property to **UnknownMember**.

Because of these changes, when Analysis Services encounters a null value for the **Subcategory** attribute or the **Model Name** attribute during processing, the unknown member value will be substituted as the key value, and the user-defined hierarchies will be constructed correctly.

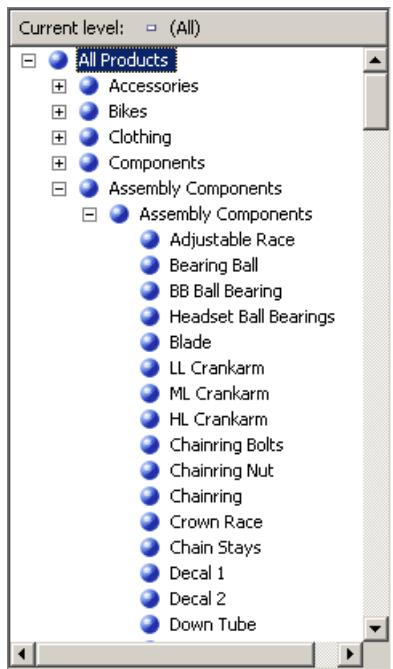

Browsing the Product Dimension Again

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab in Dimension Designer for the **Product** dimension, and then click **Reconnect**.
3. Verify that **Product Categories** is selected in the **Hierarchy** list, and then expand **All Products**.

Notice that Assembly Components appears as a new member of the Category level.

4. Expand the **Assembly Components** member of the **Category** level and then expand the **Assembly Components** member of the **Subcategory** level.

Notice that all the assembly components now appear at the **Product Name** level, as shown in the following image.

[Lesson 5: Defining Relationships Between Dimensions and Measure Groups](#)

Lesson 5: Defining Relationships Between Dimensions and Measure Groups

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In the previous lessons in this tutorial, you learned that database dimensions added to a cube can be used as the basis for one or more cube dimensions. In this lesson, you learn to define different types of relationships between cube dimensions and measure groups, and to specify the properties of these relationships.

For more information, see [Dimension Relationships](#).

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

This lesson contains the following tasks:

[Defining a Referenced Relationship](#)

In this task, you learn to link a dimension to a fact table indirectly through a dimension that is linked directly through a primary key-foreign key relationship.

[Defining a Fact Relationship](#)

In this task, you learn to define a dimension based on data in the fact table, and to define the dimension relationship as a fact relationship.

[Defining a Many-to-Many Relationship](#)

In this task, you learn to relate a fact to multiple dimension members through the definition of a many-to-many relationship between dimension tables and fact tables.

[Defining Dimension Granularity within a Measure Group](#)

In this task, you learn to modify the granularity of a dimension for a specific measure group.

[Dimension Relationships](#)

Lesson 5-1 - Defining a Referenced Relationship

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Up to this point in the tutorial, each cube dimension that you defined was based on a table that was directly linked to the fact table for a measure group by a primary key to foreign key relationship. In the tasks in this topic, you link the **Geography** dimension to the fact table for reseller sales through the **Reseller** dimension, which is called a *reference dimension*. This enables users to dimension reseller sales by geography. For more information, see [Define a Referenced Relationship and Referenced Relationship Properties](#).

Dimensioning Reseller Sales by Geography

1. In Solution Explorer, right-click **Analysis Services Tutorial** in the **Cubes** folder, and then click **Browse**.
2. Remove all hierarchies from the data pane, and then verify that the **Reseller Sales-Sales Amount** measure appears in the data area of the data pane. Add it to the data pane if it is not already there.
3. From the **Geography** dimension in the metadata pane, drag the **Geographies** user-defined hierarchy to the **Drop Row Fields Here** area of the data pane.

Notice that the **Reseller Sales-Sales Amount** measure is not correctly dimensioned by the **Country-Region** attribute members in the **Regions** hierarchy. The value for **Reseller Sales-Sales Amount** repeats for each **Country-Region** attribute member.

| Dimension | Hierarchy |
|--------------------|-----------|
| <Select dimension> | |

| Country-Region | Reseller Sales... |
|----------------|-------------------|
| Australia | 80450596.98... |
| Canada | 80450596.98... |
| France | 80450596.98... |
| Germany | 80450596.98... |
| United Kingdom | 80450596.98... |
| United States | 80450596.98... |
| Unknown | 80450596.98... |

4. Open Data Source View Designer for the **Adventure Works DW 2012** data source view.
5. In the **Diagram Organizer** pane, view the relationship between the **Geography** table and the **ResellerSales** table.

Notice that there is no direct link between these tables. However, there is an indirect link between these tables through either the **Reseller** table or the **SalesTerritory** table.

6. Double-click the arrow that represents the relationship between the **Geography** table and the **Reseller** table.

In the **Edit Relationship** dialog box, notice that the **GeographyKey** column is the primary key in the **Geography** table and the foreign key in the **Reseller** table.

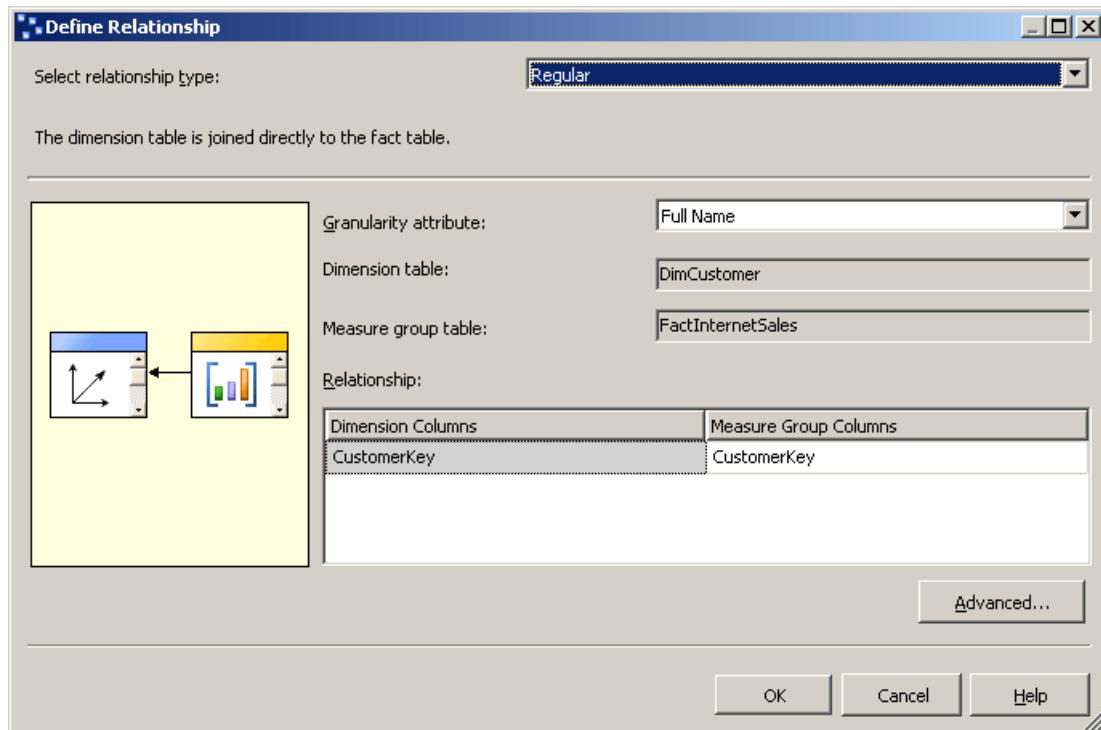

7. Click **Cancel**, switch to Cube Designer for the Analysis Services Tutorial cube, and then click the **Dimension Usage** tab.

Notice that the **Geography** cube dimension does not currently have a relationship with either the **Internet Sales** measure group or the **Reseller Sales** measure group.

8. Click the ellipsis button (...) in the **Full Name** cell at the intersection of the **Customer** dimension and the **Internet Sales** measure group.

In the **Define Relationship** dialog box, notice that a **Regular** relationship is defined between the **DimCustomer** dimension table and the **FactInternetSales** measure group table based on the **CustomerKey** column in each of these tables. All the relationships that you have defined within this tutorial up to this point have been regular relationships.

The following image shows the **Define Relationship** dialog box with a regular relationship between the **DimCustomer** dimension table and the **FactInternetSales** measure group table.

9. Click **Cancel**.
10. Click the ellipsis button (...) in the unnamed cell at the intersection of the **Geography** dimension and the **Reseller Sales** measure group.

In the **Define Relationship** dialog box, notice that no relationship is currently defined between the Geography cube dimension and the Reseller Sales measure group. You cannot define a regular relationship because there is no direct relationship between the dimension table for the Geography dimension and the fact table for the Reseller Sales measure group.

11. In the **Select relationship type** list, select **Referenced**.

You define a referenced relationship by specifying a dimension that is directly connected to the measure group table, called an *intermediate dimension*, that Analysis Services can use to link the reference dimension to the fact table. You then specify the attribute that links the reference dimension to the intermediate dimension.

12. In the **Intermediate dimension** list, select **Reseller**.

The underlying table for the Geography dimension is linked to the fact table through the underlying table for the Reseller dimension.

13. In the **Reference dimension attribute** list, select **Geography Key**, and then try to select **Geography Key** in the **Intermediate dimension attribute** list.

Notice that **Geography Key** does not appear in the **Intermediate dimension attribute** list. This is because the **GeographyKey** column is not defined as an attribute in the **Reseller** dimension.

14. Click **Cancel**.

In the next task, you will solve this problem by defining an attribute that is based on the GeographyKey column in the Reseller dimension.

Defining the Intermediate Dimension Attribute and the Referenced Dimension Relationship

1. Open Dimension Designer for the **Reseller** dimension, and view the columns in the **Reseller** table in the **Data Source View** pane, and view the defined attributes in the **Reseller** dimension in the **Attributes** pane.

Notice that although GeographyKey is defined as a column in the Reseller table, no dimension attribute is defined in the Reseller dimension based on this column. Geography is defined as a dimension attribute in the Geography dimension because it is the key column that links the underlying table for that dimension to the fact table.

2. To add a **Geography Key** attribute to the **Reseller** dimension, right-click **GeographyKey** in the **Data Source View** pane, and then click **New Attribute from Column**.
3. In the **Attributes** pane, select **Geography Key**, and then, in the Properties window, set the **AttributeHierarchyOptimizedState** property to **NotOptimized**, the **AttributeHierarchyOrdered** property to **False**, and the **AttributeHierarchyVisible** property to **False**.

The Geography Key attribute in the Reseller dimension will only be used to link the Geography dimension to the Reseller Sales fact table. Because it will not be used for browsing, there is no value in defining this attribute hierarchy as visible. Additionally, ordering and optimizing the attribute hierarchy will only negatively affect processing performance. However, the attribute must be enabled to serve as the link between the two dimensions.

4. Switch to Cube Designer for the Analysis Services Tutorial cube, click the **Dimension Usage** tab, and then click the ellipsis button (...) at the intersection of the **Reseller Sales** measure group and the **Geography** cube dimension.
5. In the **Select relationship type** list, select **Referenced**.
6. In the **Intermediate dimension** list, select **Reseller**.
7. In the **Reference dimension attribute** list, select **Geography Key**, and then select **Geography Key** in the **Intermediate dimension attribute** list.

Notice that the **Materialize** check box is selected. This is the default setting for MOLAP dimensions. Materializing the dimension attribute link causes the value of the link between the fact table and the reference dimension for each row to be materialized, or stored, in the dimension's MOLAP structure during processing. This will have a minor effect on processing performance and storage requirements, but will increase query performance (sometimes significantly).

8. Click **OK**.

Notice that the **Geography** cube dimension is now linked to the **Reseller Sales** measure group. The icon indicates that the relationship is a referenced dimension relationship.

9. In the **Dimensions** list on the **Dimension Usage** tab, right-click **Geography**, and then click **Rename**.
10. Change the name of this cube dimension to **Reseller Geography**.

Because this cube dimension is now linked to the **Reseller Sales** measure group, users will benefit from

explicitly defining its use in the cube, to avoid possible user confusion.

Successfully Dimensioning Reseller Sales by Geography

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click the **Reconnect** button.
3. In the metadata pane, expand **Reseller Geography**, right-click **Geographies**, and then click **Add to Row Area**.

Notice that the **Reseller Sales-Sales Amount** measure is now correctly dimensioned by the **Country-Region** attribute of the **Geographies** user-defined hierarchy, as shown in the following image.

| Dimension | Hierarchy |
|-----------|-----------|
| | |

| Country-Region | Reseller Sales-Sales Am.. |
|----------------|---------------------------|
| | |
| | |
| | |
| | |
| | |
| | |

Next Task in Lesson

[Defining a Fact Relationship](#)

See Also

[Attribute Relationships](#)

[Define a Referenced Relationship and Referenced Relationship Properties](#)

Lesson 5-2 - Defining a Fact Relationship

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Users sometimes want to be able to dimension measures by data items that are in the fact table or to query the fact table for specific additional related information, such as invoice numbers or purchase order numbers related to specific sales facts. When you define a dimension based on such a fact table item, the dimension is called a *fact dimension*. Fact dimensions are also known as degenerate dimensions. Fact dimensions are useful for grouping together related fact table rows, such as all the rows that are related to a particular invoice number. Although you can put this information in a separate dimension table in the relational database, creating a separate dimension table for the information provides no benefit because the dimension table would grow at the same rate as the fact table, and would just create duplicate data and unnecessary complexity.

Within Analysis Services, you can determine whether to duplicate the fact dimension data in a MOLAP dimension structure for increased query performance, or whether to define the fact dimension as a ROLAP dimension to save storage space at the expense of query performance. When you store a dimension with the MOLAP storage mode, all the dimension members are stored in the instance of Analysis Services in a highly compressed MOLAP structure, in addition to being stored in the measure group's partitions. When you store a dimension with the ROLAP storage mode, only the dimension definition is stored in the MOLAP structure—the dimension members themselves are queried from the underlying relational fact table at query time. You decide the appropriate storage mode based on how frequently the fact dimension is queried, the number of rows returned by a typical query, the performance of the query, and the processing cost. Defining a dimension as ROLAP does not require that all cubes that use the dimension also be stored with the ROLAP storage mode. The storage mode for each dimension can be configured independently.

When you define a fact dimension, you can define the relationship between the fact dimension and the measure group as a fact relationship. The following constraints apply to fact relationships:

- The granularity attribute must be the key column for the dimension, which creates a one-to-one relationship between the dimension and the facts in the fact table.
- A dimension can have a fact relationship with only a single measure group.

NOTE

Fact dimensions must be incrementally updated after every update to the measure group that the fact relationship references.

For more information, see [Dimension Relationships](#), and [Define a Fact Relationship and Fact Relationship Properties](#).

In the tasks in this topic, you add a new cube dimension based on the **CustomerPONumber** column in the **FactInternetSales** fact table. You then define the relationship between this new cube dimension and the **Internet Sales** measure group as a fact relationship.

Defining the Internet Sales Orders Fact Dimension

1. In Solution Explorer, right-click **Dimensions**, and then click **New Dimension**.
2. On the **Welcome to the Dimension Wizard** page, click **Next**.

3. On the **Select Creation Method** page, verify that the **Use an existing table** option is selected, and then click **Next**.
4. On the **Specify Source Information** page, verify that the **Adventure Works DW 2012** data source view is selected.
5. In the **Main table** list, select **InternetSales**.
6. In the **Key columns** list, verify that **SalesOrderNumber** and **SalesOrderLineNumber** are listed.
7. In the **Name column** list, select **SalesOrderLineNumber**.
8. Click **Next**.
9. On the **Select Related Tables** page, clear the check boxes beside all of the tables, and then click **Next**.
10. On the **Select Dimension Attributes** page, click the check box in the header twice to clear all of the check boxes. The **Sales Order Number** attribute will remain selected because it is the key attribute.
11. Select the **Customer PO Number** attribute, and then click **Next**.
12. On the **Completing the Wizard** page, change the name to **Internet Sales Order Details** and then click **Finish** to complete the wizard.
13. On the **File** menu, click **Save All**.
14. In the **Attributes** pane of the Dimension Designer for the **Internet Sales Order Details** dimension, select **Sales Order Number**, and then change the **Name** property in the Properties window to **Item Description**.
15. In the **NameColumn** property cell, click the browse button (...). In the **Name Column** dialog box, select **Product** from the **Source table** list, select **EnglishProductName** for the **Source column**, and then click **OK**.
16. Add the **Sales Order Number** attribute to the dimension by dragging the **SalesOrderNumber** column from the **InternetSales** table in the **Data Source View** pane to the **Attributes** pane.
17. Change the **Name** property of the new **Sales Order Number** attribute to **Order Number**, and change the **OrderBy** property to **Key**.
18. In the **Hierarchies** pane, create an **Internet Sales Orders** user hierarchy that contains the **Order Number** and **Item Description** levels, in that order.
19. In the **Attributes** pane, select **Internet Sales Order Details**, and then review the value for the **StorageMode** property in the Properties window.

Notice that, by default, this dimension is stored as a MOLAP dimension. Although changing the storage mode to ROLAP will save processing time and storage space, it occurs at the expense of query performance. For the purposes of this tutorial, you will use MOLAP as the storage mode.
20. To add the newly created dimension to the Analysis Services Tutorial cube as a cube dimension, switch to **Cube Designer**. On the **Cube Structure** tab, right-click in the **Dimensions** pane and select **Add Cube Dimension**.
21. In the **Add Cube Dimension** dialog box, select **Internet Sales Order Details** and then click **OK**.

Defining a Fact Relationship for the Fact Dimension

1. In the Cube Designer for the Analysis Services Tutorial cube, click the **Dimension Usage** tab.

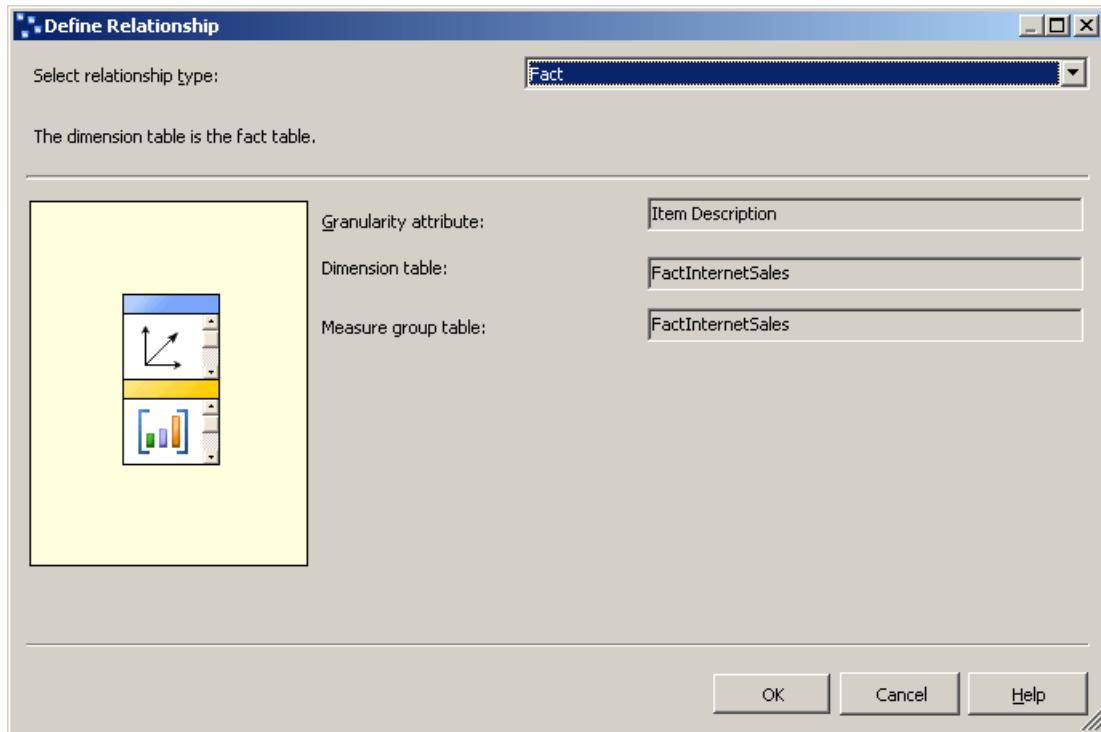

Notice that the **Internet Sales Order Details** cube dimension is automatically configured as having a fact

relationship, as shown by the unique icon.

2. Click the browse button (...) in the **Item Description** cell, at the intersection of the **Internet Sales** measure group and the **Internet Sales Order Details** dimension, to review the fact relationship properties.

The **Define Relationship** dialog box opens. Notice that you cannot configure any of the properties.

The following image shows the fact relationship properties in the **Define Relationship** dialog box.

3. Click **Cancel**.

Browsing the Cube by Using the Fact Dimension

1. On the **Build** menu, click **Deploy Analysis Services Tutorial** to deploy the changes to the instance of Analysis Services and process the database.
2. After deployment has successfully completed, click the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click the **Reconnect** button.
3. Clear all measures and hierarchies from the data pane, and then add the **Internet Sales-Sales Amount** measure to the data area of the data pane.
4. In the metadata pane, expand **Customer**, expand **Location**, expand **Customer Geography**, expand **Members**, expand **All Customers**, expand **Australia**, expand **Queensland**, expand **Brisbane**, expand **4000**, right-click **Adam Powell**, and then click **Add to Filter**.

Filtering to limit the sales orders returned to a single customer lets the user drill down to the underlying detail in a large fact table without suffering a significant loss in query performance.

5. Add the **Internet Sales Orders** user-defined hierarchy from the **Internet Sales Order Details** dimension to the row area of the data pane.

Notice that the sales order numbers and the corresponding Internet sales amounts for Adam Powell appear in the data pane.

The following image shows the result of the previous steps.

| Dimension | Hierarchy | Operator | Filter Expression |
|--------------------|--|--------------------------|-------------------|
| Customer |  Customer Geography | Equal | { Adam Powell } |
| <Select dimension> | | | |
|
 | | | |
| Order Number | Item Description | Internet Sales-Sales ... | |
| SO49206 | Road-250 Black, 48 | 2181.5625 | |
| SO61522 | Road-350-W Yellow, 48 | 1700.99 | |
| SO61522 | Short-Sleeve Classic Jersey, XL | 53.99 | |

Next Task in Lesson

[Defining a Many-to-Many Relationship](#)

See Also

[Dimension Relationships](#)

[Define a Fact Relationship and Fact Relationship Properties](#)

Lesson 5-3 - Defining a Many-to-Many Relationship

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you define a dimension, typically each fact joins to one and only one dimension member, whereas a single dimension member can be associated with many different facts. For example, each customer can have many orders but each order belongs to a single customer. In relational database terminology, this is referred to as a *one-to-many relationship*. However, sometimes a single fact can join to multiple dimension members. In relational database terminology, this is referred to as a *many-to-many relationship*. For example, a customer may have multiple reasons for making a purchase, and a purchase reason can be associated with multiple purchases. A join table is used to define the sales reasons that relate to each purchase. A Sales Reason dimension constructed from such relationships would then have multiple members that relate to a single sales transaction. Many-to-many dimensions expand the dimensional model beyond the classic star schema and support complex analytics when dimensions are not directly related to a fact table.

In Analysis Services, you define a many-to-many relationship between a dimension and a measure group by specifying an intermediate fact table that is joined to the dimension table. An intermediate fact table is joined, in turn, to an intermediate dimension table to which the fact table is joined. The many-to-many relationships between the intermediate fact table and both the dimension tables in the relationship and the intermediate dimension creates the many-to-many relationships between members of the primary dimension and measures in the measure group that is specified by the relationship. In order to define a many-to-many relationship between a dimension and a measure group through an intermediate measure group, the intermediate measure group must share one or more dimensions with the original measure group.

With a many-to-many dimension, values are distinct summed, which means that they do not aggregate more than once to the All member.

NOTE

In order to support a many-to-many dimension relationship, a primary key-foreign key relationship must be defined in the data source view between all the tables that are involved. Otherwise, you will not be able to select the correct intermediate measure group when you establish the relationship in the **Dimension Usage** tab of Cube Designer.

For more information, see [Dimension Relationships](#), and [Define a Many-to-Many Relationship and Many-to-Many Relationship Properties](#).

In the tasks in this topic, you define the Sales Reasons dimension and the Sales Reasons measure group, and you define a many-to-many relationship between the Sales Reasons dimension and the Internet Sales measure group through the Sales Reasons measure group.

Adding Required Tables to the Data Source View

1. Open Data Source View Designer for the **Adventure Works DW 2012** data source view.
2. Right-click anywhere in the **Diagram Organizer** pane, click **New Diagram**, and specify **Internet Sales Order Reasons** as the name for this new diagram.
3. Drag the **InternetSales** table to the **Diagram** pane from the **Tables** pane.
4. Right-click anywhere in the **Diagram** pane, and then click **Add/Remove Tables**.

5. In the **Add/Remove Tables** dialog box, add the **DimSalesReason** table and the **FactInternetSalesReason** table to the **Included objects** list, and then click **OK**.

Notice that the primary key-foreign key relationships between the tables that are involved are established automatically because those relationships are defined in the underlying relational database. If these relationships were not defined in the underlying relational database, you would have to define them in the data source view.

6. On the **Format** menu, point to **Auto Layout**, and then click **Diagram**.
7. In the Properties window, change the **FriendlyName** property of the **DimSalesReason** table to **SalesReason**, and then change the **FriendlyName** property of the **FactInternetSalesReason** table to **InternetSalesReason**.
8. In the **Tables** pane, expand **InternetSalesReason (dbo.FactInternetSalesReason)**, click **SalesOrderNumber**, and then review the **Data Type** property for this data column in the Properties window.

Notice that the data type for the **SalesOrderNumber** column is a string data type.

9. Review the data types for the other columns in the **InternetSalesReason** table.

Notice that the data types for the other two columns in this table are numeric data types.

10. In the **Tables** pane, right-click **InternetSalesReason (dbo.FactInternetSalesReason)**, and then click **Explore Data**.

Notice that, for each line number within each order, a key value identifies the sales reason for the purchase of that line item, as shown in the following image.

| SalesOrderNu | SalesOrderLin | SalesReasonK |
|--------------|---------------|--------------|
| SO43697 | 1 | 5 |
| SO43697 | 1 | 9 |
| SO43702 | 1 | 5 |
| SO43702 | 1 | 9 |
| SO43703 | 1 | 5 |
| SO43703 | 1 | 9 |
| SO43706 | 1 | 5 |
| SO43706 | 1 | 9 |
| SO43707 | 1 | 5 |
| SO43707 | 1 | 9 |
| SO43709 | 1 | 5 |
| SO43709 | 1 | 9 |
| SO43710 | 1 | 5 |
| SO43710 | 1 | 9 |
| SO43711 | 1 | 5 |
| SO43711 | 1 | 9 |
| SO43712 | 1 | 5 |

Defining the Intermediate Measure Group

1. Switch to Cube Designer for the Analysis Services Tutorial cube, and then click the **Cube Structure** tab.
2. Right-click anywhere in the **Measures** pane, and then click **New Measure Group**. For more information, see [Create Measures and Measure Groups in Multidimensional Models](#).
3. In the **New Measure Group** dialog box, select **InternetSalesReason** in the **Select a table from the data source view** list, and then click **OK**.
4. Expand the **Internet Sales Reason** measure group.

Notice that the **Internet Sales Reason** measure group now appears in the **Measures** pane.

Notice that only a single measure is defined for this new measure group, the **Internet Sales Reason Count** measure.

5. Select **Internet Sales Reason Count** and review the properties of this measure in the Properties window.

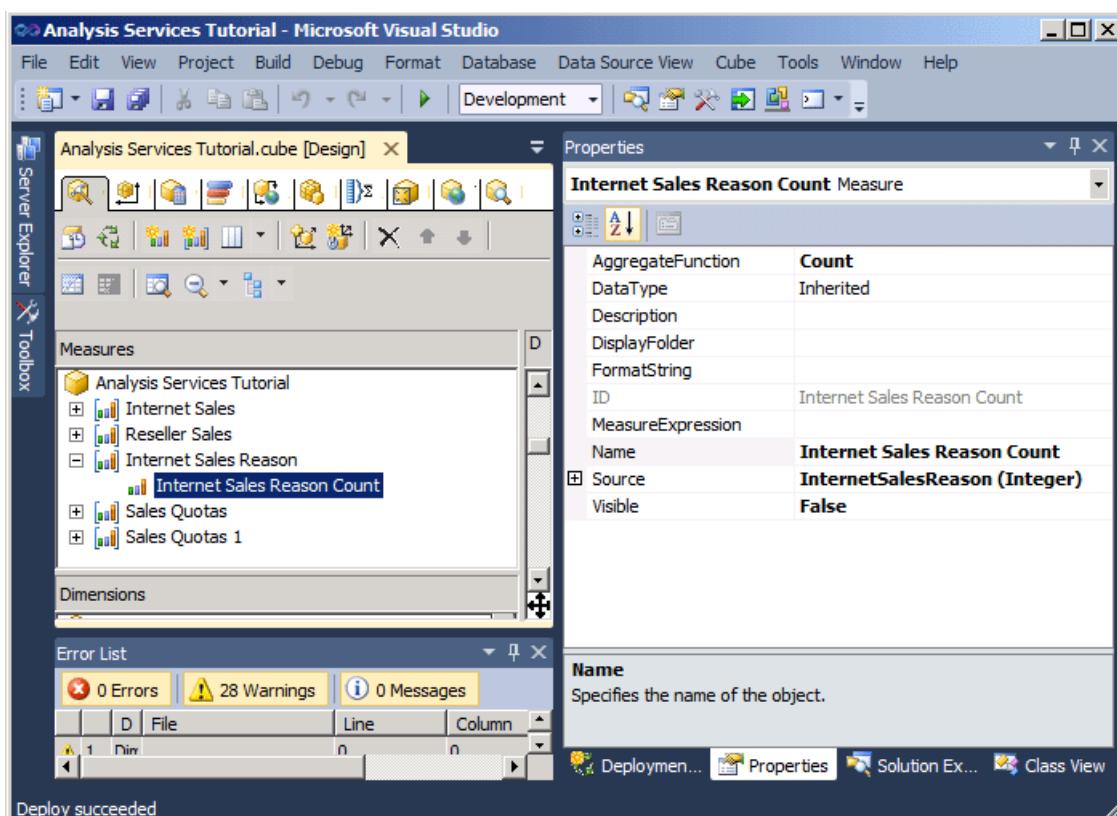

Notice that the **AggregateFunction** property for this measure is defined as **Count** instead of **Sum**.

Analysis Services chose **Count** because the underlying data type is a string data type. The other two columns in the underlying fact table were not selected as measures because Analysis Services detected them as numeric keys instead of as actual measures. For more information, see [Define Semiadditive Behavior](#).

6. In the Properties window, change the **Visible** property of the **Internet Sales Reason Count** measure to **False**.

This measure will only be used to join the Sales Reason dimension that you will define next to the Internet Sales measure group. Users will not browse this measure directly.

The following image shows the properties for the **Internet Sales Reason Count** measure.

Defining the Many-to-Many Dimension

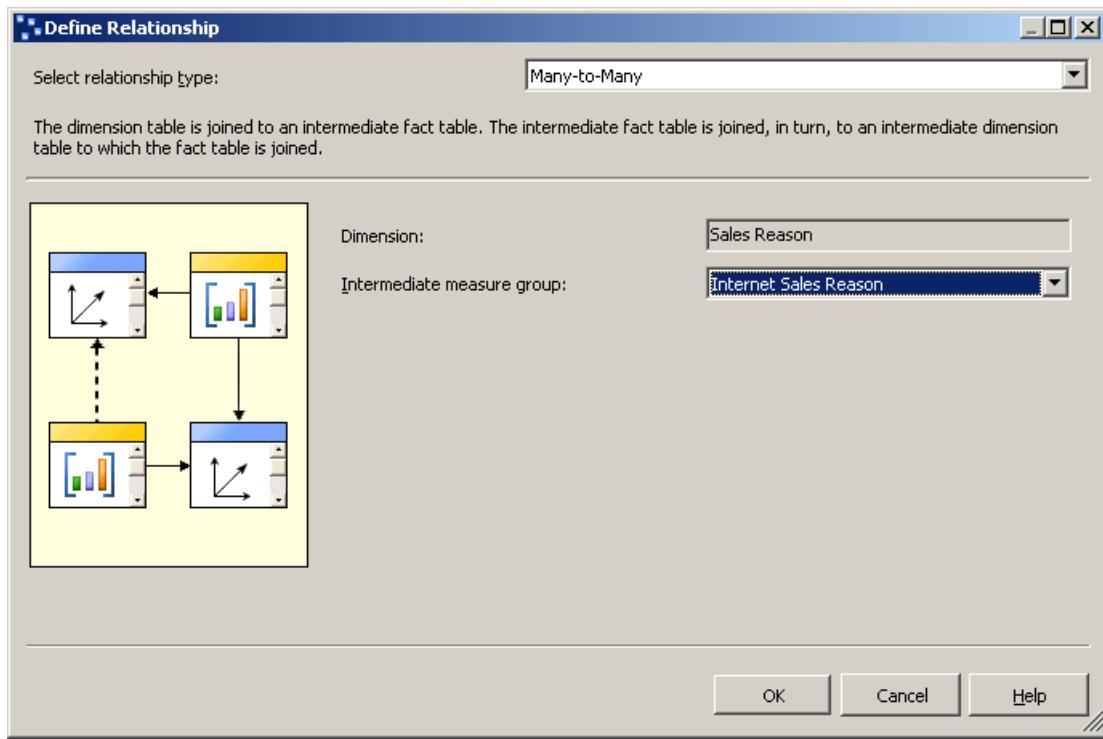

1. In Solution Explorer, right-click **Dimensions**, and then click **New Dimension**.
2. On the **Welcome to the Dimension Wizard** page, click **Next**.
3. On the **Select Creation Method** page, verify that the **Use an existing table** option is selected, and then click **Next**.
4. On the **Specify Source Information** page, verify that the Adventure Works DW 2012 data source view is selected.
5. In the **Main table** list, select **SalesReason**.
6. In the **Key columns** list, verify that **SalesReasonKey** is listed.
7. In the **Name column** list, select **SalesReasonName**.

8. Click **Next**.
9. On the **Select Dimension Attributes** page, the **Sales Reason Key** attribute is automatically selected because it is the key attribute. Select the check box beside the **Sales Reason Reason Type** attribute, change its name to **Sales Reason Type**, and then click **Next**.
10. On the **Completing the Wizard** page, click **Finish** to create the Sales Reason dimension.
11. On the **File** menu, click **Save All**.
12. In the **Attributes** pane of the Dimension Designer for the **Sales Reason** dimension, select **Sales Reason Key**, and then change the **Name** property in the Properties window to **Sales Reason**.
13. In the **Hierarchies** pane of the Dimension Designer, create a **Sales Reasons** user hierarchy that contains the **Sales Reason Type** level and the **Sales Reason** level, in that order.
14. In the Properties window, define **All Sales Reasons** as the value for the **AllMemberName** property of the Sales Reasons hierarchy.
15. Define **All Sales Reasons** as the value for **AttributeAllMemberName** property of the Sales Reason dimension.
16. To add the newly created dimension to the Analysis Services Tutorial cube as a cube dimension, switch to **Cube Designer**. On the **Cube Structure** tab, right-click in the **Dimensions** pane and select **Add Cube Dimension**.
17. In the **Add Cube Dimension** dialog box, select **Sales Reason** and then click **OK**.
18. On the **File** menu, click **Save All**.

Defining the Many to Many Relationship

1. Switch to Cube Designer for the Analysis Services Tutorial cube, and then click the **Dimension Usage** tab.
- Notice that the **Sales Reason** dimension has a regular relationship defined with the **Internet Sales Reason** measure group, but has no relationship defined with the **Internet Sales** or **Reseller Sales** measure groups. Notice also that the **Internet Sales Order Details** dimension has a regular relationship defined with the **Internet Sales Reason** dimension, which in turn has a **Fact Relationship** with the **Internet Sales** measure group. If this dimension was not present (or another dimension with a relationship with both the **Internet Sales Reason** and the **Internet Sales** measure group were not present), you would not be able to define the many-to-many relationship.
2. Click the cell at the intersection of the **Internet Sales** measure group and the **Sales Reason** dimension and then click the browse button (...).
 3. In the **Define Relationship** dialog box, select **Many-to-Many** in the **Select relationship type** list.
- You have to define the intermediate measure group that connects the Sales Reason dimension to the Internet Sales measure group.
4. In the **Intermediate measure group** list, select **Internet Sales Reason**.

The following image shows the changes in the **Define Relationship** dialog box.

5. Click **OK**.

Notice the many-to-many icon that represents the relationship between the Sales Reason dimension and the Internet Sales measure group.

Browsing the Cube and the Many-to-Many Dimension

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click **Reconnect**.
3. Add the **Internet Sales-Sales Amount** measure to the data area of the data pane.
4. Add the **Sales Reasons** user-defined hierarchy from the **Sales Reason** dimension to the row area of the data pane.
5. In the metadata pane, expand **Customer**, expand **Location**, expand **Customer Geography**, expand **Members**, expand **All Customers**, expand **Australia**, right-click **Queensland**, and then click **Add to Filter**.
6. Expand each member of the **Sales Reason Type** level to review the dollar values that are associated with each reason a customer in Queensland gave for their purchase of an Adventure Works product over the Internet.

Notice that the totals that are associated with each sales reason add up to more than the total sales. This is because some customers cited multiple reasons for their purchase.

The following image shows the **Filter** pane and **Data** pane of Cube Designer.

| Dimension | Hierarchy | Operator | Filter Expression |
|---|--|-----------------|-------------------|
| Customer |  Customer Geography | Equal | { Queensland } |
| <Select dimension> | | | |
|   | | | |
| Sales Reaso... | Sales Reason | Internet Sal... | |
| Marketing | Television ... | 1203.54 | |
| Other | Manufacturer | 424760.16 | |
| Other | Other | 11041.43 | |
| Other | Price | 569067.13... | |
| Other | Quality | 375718.35 | |
| Other | Review | 157451.962 | |
| Promotion | On Promotion | 454888.43 | |

Lesson 5-4 - Defining Dimension Granularity within a Measure Group

7/16/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Users will want to dimension fact data at different granularity or specificity for different purposes. For example, sales data for reseller or internet sales may be recorded for each day, whereas sales quota information may only exist at the month or quarter level. In these scenarios, users will want a time dimension with a different grain or level of detail for each of these different fact tables. While you could define a new database dimension as a time dimension with this different grain, there is an easier way with Analysis Services.

By default in Analysis Services, when a dimension is used within a measure group, the grain of the data within that dimension is based on the key attribute of the dimension. For example, when a time dimension is included within a measure group and the default grain of the time dimension is daily, the default grain of that dimension within the measure group is daily. Many times this is appropriate, such as for the **Internet Sales** and **Reseller Sales** measure groups in this tutorial. However, when such a dimension is included in other types of measure groups, such as in a sales quota or budget measure group, a monthly or quarterly grain is generally more appropriate.

To specify a grain for a cube dimension other than the default grain, you modify the granularity attribute for a cube dimension as used within a particular measure group on the **Dimension Usage** tab of Cube Designer. When you change the grain of a dimension within a specific measure group to an attribute other than the key attribute for that dimension, you must guarantee that all other attributes in the measure group are directly or indirectly related to new granularity attribute. You do this by specifying attribute relationships between all other attributes and the attribute that is specified as the granularity attribute in the measure group. In this case, you define additional attribute relationships rather than move attribute relationships. The attribute that is specified as the granularity attribute effectively becomes the key attribute within the measure group for the remaining attributes in the dimension. If you do not specify attribute relationships appropriately, Analysis Services will not be able to aggregate values correctly, as you will see in the tasks in this topic.

For more information, see [Dimension Relationships, Define a Regular Relationship and Regular Relationship Properties](#).

In the tasks in this topic, you add a Sales Quotas measure group and define the granularity of the Date dimension in this measure group to be monthly. You then define attribute relationships between the month attribute and other dimension attributes to ensure that Analysis Services aggregates values correctly.

Adding Tables and Defining the Sales Quotas Measure Group

1. Switch to the **Adventure Works DW 2012** data source view.
2. Right-click anywhere in the **Diagram Organizer** pane, click **New Diagram**, and then name the diagram **Sales Quotas**.
3. Drag the **Employee**, **Sales Territory**, and **Date** tables from the **Tables** pane to the **Diagram** pane.
4. Add the **FactSalesQuota** table to the **Diagram** pane by right-clicking anywhere in the **Diagram** pane and selecting **Add/Remove Tables**.

Notice that the **SalesTerritory** table is linked to the **FactSalesQuota** table through the **Employee** table.

5. Review the columns in the **FactSalesQuota** table and then explore the data in this table.

Notice that the grain of the data within this table is the calendar quarter, which is the lowest level of detail in the FactSalesQuota table.

6. In Data Source View Designer, change the **FriendlyName** property of the **FactSalesQuota** table to **SalesQuotas**.
7. Switch to the Analysis Services Tutorial cube, and then click the **Cube Structure** tab.
8. Right-click anywhere in the **Measures** pane, click **New Measure Group**, click **SalesQuotas** in the **New Measure Group** dialog box, and then click **OK**.

The **Sales Quotas** measure group appears in the **Measures** pane. In the **Dimensions** pane, notice that a new **Date** cube dimension is also defined, based on the **Date** database dimension. A new time-related cube dimension is defined because Analysis Services does not know which of the existing time-related cube dimensions to relate to the **DateKey** column in the **FactSalesQuota** fact table that underlies the Sales Quotas measure group. You will change this later in another task in this topic.

9. Expand the **Sales Quotas** measure group.
10. In the **Measures** pane, select **Sales Amount Quota**, and then set the value for the **FormatString** property to **Currency** in the Properties window.
11. Select the **Sales Quotas Count** measure, and then type **#,#** as the value for the **FormatString** property in the Properties window.
12. Delete the **Calendar Quarter** measure from the **Sales Quotas** measure group.

Analysis Services detected the column that underlies the Calendar Quarter measure as a column that contains measures. However, this column and the CalendarYear column contain the values that you will use to link the Sales Quotas measure group to the Date dimension later in this topic.

13. In the **Measures** pane, right-click the **Sales Quotas** measure group, and then click **New Measure**.
The **New Measure** dialog box opens, containing the available source columns for a measure with a usage type of **Sum**.

14. In the **New Measure** dialog box, select **Distinct count** in the **Usage** list, verify that **SalesQuotas** is selected in the **Source table** list, select **EmployeeKey** in the **Source column** list, and then click **OK**.

Notice that the measure is created in a new measure group named **Sales Quotas 1**. Distinct count measures in SQL Server are created in their own measure groups to maximize processing performance.

15. Change the value for the **Name** property for the **Employee Key Distinct Count** measure to **Sales Person Count**, and then type **#,#** as the value for the **FormatString** property.

Browsing the Measures in the Sales Quota Measure Group by Date

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click the **Reconnect** button.
3. Click the Excel shortcut, and then click **Enable**.
4. In the PivotTable Field List, expand the **Sales Quotas** measure group, and then drag the **Sales Amount Quota** measure to the Values area.
5. Expand the **Sales Territory** dimension, and then drag the **Sales Territories** user-defined hierarchy to Row Labels.

Notice that the Sales Territory cube dimension is not related, directly or indirectly, to the Fact Sales Quota

table, as shown in the following image.

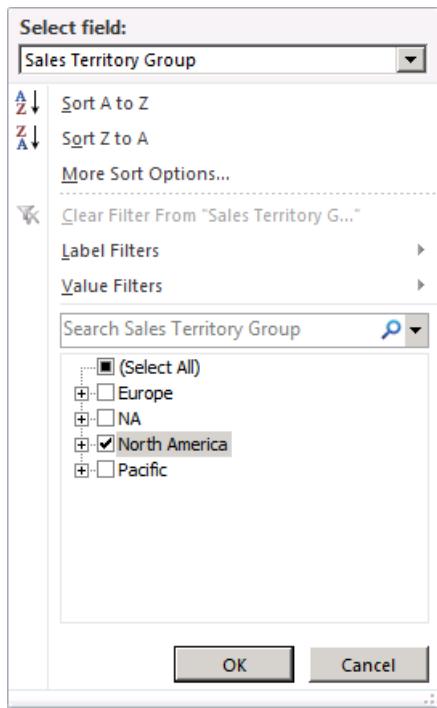

The screenshot shows a Microsoft Excel window titled "Book1 - Microsoft Excel". The ribbon at the top has the "PivotTable Tools" tab selected, with sub-options "Options", "Design", and "Format". The main area displays a PivotTable with data in columns A, B, and C. Row 1 is labeled "Row Labels" and contains "Sales Amount Quota". Rows 2 through 11 list regions and their corresponding sales amounts: Europe (\$95,714,000.00), France (\$95,714,000.00), Germany (\$95,714,000.00), United Kingdom (\$95,714,000.00), NA (\$95,714,000.00), North America (\$95,714,000.00), Canada (\$95,714,000.00), United States (\$95,714,000.00), Pacific (\$95,714,000.00), and Grand Total (\$95,714,000.00). The PivotTable Field List pane on the right shows the "Sales Territories" user-defined hierarchy under "Sales Territory". The "Report Filter" section shows "Sales Territories" selected. The status bar at the bottom indicates "Ready" and "tmp6824".

In the next series of steps in this topic you will define a reference dimension relationship between this dimension and this fact table.

6. Move the **Sales Territories** user hierarchy from the Rows Labels area to the Column Labels area.
7. In the PivotTable Field list, select the **Sales Territories** user-defined hierarchy, and then click the down arrow to the right.

The screenshot shows the "PivotTable Field List" pane. The "Show fields related to:" dropdown is set to "(All)". Under "Sales Territory", the "Sales Territories" user-defined hierarchy is selected, indicated by an orange border around the "Sales Territories" node. Other nodes like "Sales Territory Group", "Sales Territory Country", and "Sales Territory Region" are listed below it. The status bar at the bottom indicates "Ready" and "tmp6824".

8. In the filter, click the Select All checkbox to clear all the selections, and then choose just **North America**.

9. In the PivotTable Field List, expand **Date**.
10. Drag the **Date.Fiscal Date** user hierarchy to Row Labels
11. On the PivotTable, click the down arrow next to Row Labels. Clear all of the years except for **FY 2008**.

Notice that only the **July 2007** member of the **Month** level appears, instead of the **July, 2007, August, 2007**, and **September, 2007** members of **Month** level, and that only the **July 1, 2007** member of the **Date** level appears, instead of all 31 days. This behavior occurs because the grain of the data in the fact table is at the quarter level and the grain of the **Date** dimension is the daily level. You will change this behavior in the next task in this topic.

Notice also that the **Sales Amount Quota** value for the month and day levels is the same value as for the quarter level, \$13,733,000.00. This is because the lowest level of data in the Sales Quotas measure group is at the quarter level. You will change this behavior in Lesson 6.

The following image shows the values for **Sales Amount Quota**.

The screenshot shows a Microsoft Excel window with the 'PivotTable Tools' ribbon tab selected. A PivotTable is displayed in the main area, showing sales data for North America. The data includes columns for Sales Amount, Quota, and various time periods (FY 2008, H1 FY 2008, Q1 FY 2008, July 2007, etc.). The PivotTable Field List pane is open on the right, showing the 'Date' dimension with 'Date.Fiscal Date' selected. The main grid shows sales data for North America, broken down by year and month.

Defining Dimension Usage Properties for the Sales Quotas Measure Group

1. Open Dimension Designer for the **Employee** dimension, right-click **SalesTerritoryKey** in the **Data Source View** pane, and then click **New Attribute from Column**.
2. In the **Attributes** pane, select **SalesTerritoryKey**, and then set the **AttributeHierarchyVisible** property to **False** in the Properties window, set the **AttributeHierarchyOptimizedState** property to **NotOptimized**, and set the **AttributeHierarchyOrdered** property to **False**.

This attribute is required to link the **Sales Territory** dimension to the **Sales Quotas** and **Sales Quotas 1** measure groups as a referenced dimension.

3. In Cube Designer for the Analysis Services Tutorial cube, click the **Dimension Usage** tab, and then review the dimension usage within the **Sales Quotas** and **Sales Quotas 1** measure groups.

Notice that the **Employee** and **Date** cube dimensions are linked to the **Sales Quotas** and **Sales Quotas 1** measure groups through regular relationships. Notice also that the **Sales Territory** cube dimension is not linked to either of these measure groups.

4. Click the cell at the intersection of the **Sales Territory** dimension and the **Sales Quotas** measure group and then click the browse button (...). The **Define Relationship** dialog box opens.
5. In the **Select relationship type** list, select **Referenced**.
6. In the **Intermediate dimension** list, select **Employee**.
7. In the **Reference dimension attribute** list, select **Sales Territory Region**.
8. In the **Intermediate dimension attribute** list, select **Sales Territory Key**. (The key column for the Sales Territory Region attribute is the SalesTerritoryKey column.)
9. Verify that the **Materialize** check box is selected.
10. Click **OK**.

11. Click the cell at the intersection of the **Sales Territory** dimension and the **Sales Quotas 1** measure group and then click the browse button (...). The **Define Relationship** dialog box opens.
12. In the **Select relationship type** list, select **Referenced**.
13. In the **Intermediate dimension** list, select **Employee**.
14. In the **Reference dimension attribute** list, select **Sales Territory Region**.
15. In the **Intermediate dimension attribute** list, select **Sales Territory Key**. (The key column for the Sales Territory Region attribute is the SalesTerritoryKey column.)
16. Verify that the **Materialize** check box is selected.
17. Click **OK**.
18. Delete the **Date** cube dimension.

Instead of having four time-related cube dimensions, you will use the **Order Date** cube dimension in the **Sales Quotas** measure group as the date against which sales quotas will be dimensioned. You will also use this cube dimension as the primary date dimension in the cube.

19. In the **Dimensions** list, rename the **Order Date** cube dimension to **Date**.
Renaming the **Order Date** cube dimension to **Date** makes it easier for users to understand its role as the primary date dimension in this cube.
20. Click the browse button (...) in the cell at the intersection of the **Sales Quotas** measure group and the **Date** dimension.
21. In the **Define Relationship** dialog box, select **Regular** in the **Select relationship type** list.
22. In the **Granularity attribute** list, select **Calendar Quarter**.
Notice that a warning appears to notify you that because you have selected a non-key attribute as the granularity attribute, you must make sure that all other attributes are directly or indirectly related to the granularity attribute by specifying them as member properties.
23. In the **Relationship** area of the **Define Relationship** dialog box, link the **CalendarYear** and **CalendarQuarter** dimension columns from the table that underlies the Date cube dimension to the **CalendarYear** and **CalendarQuarter** columns in the table that underlies the Sales Quota measure group, and then click **OK**.

NOTE

The Calendar Quarter is defined as the granularity attribute for the Date cube dimension in the Sales Quotas measure group, but the Date attribute continues to be the granularity attribute for the Internet Sales and Reseller Sales measure groups.

24. Repeat the previous four steps for the **Sales Quotas 1** measure group.

Defining Attribute Relationships Between the Calendar Quarter Attribute and the Other Dimension Attributes in the Date Dimension

1. Switch to **Dimension Designer** for the **Date** dimension, and then click the **Attribute Relationships** tab.

Notice that although **Calendar Year** is linked to **Calendar Quarter** through the **Calendar Semester** attribute, the fiscal calendar attributes are linked only to one another; they are not linked to the **Calendar Quarter** attribute and therefore will not aggregate correctly in the **Sales Quotas** measure group.

2. In the diagram, right-click the **Calendar Quarter** attribute and then select **New Attribute Relationship**.
3. In the **Create Attribute Relationship** dialog box, the **Source Attribute** is **Calendar Quarter**. Set the **Related Attribute** to **Fiscal Quarter**.
4. Click **OK**.

Notice that a warning message appears stating that the **Date** dimension contains one or more redundant attribute relationships that may prevent data from being aggregated when a non-key attribute is used as a granularity attribute.

5. Delete the attribute relationship between the **Month Name** attribute and the **Fiscal Quarter** attribute.
6. On the **File** menu, click **Save All**.

Browsing the Measures in the Sales Quota Measure Group by Date

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click **Reconnect**.
3. Click the Excel shortcut, and then click **Enable**.
4. Drag the **Sales Amount Quota** measure to the Values area.
5. Drag the **Sales Territories** user hierarchy to the Column Labels, and then filter on **North America**.
6. Drag the **Date.FiscalDate** user hierarchy to the Row Labels, and then click the down arrow next to **Row Labels** on the PivotTable, and clear all check boxes other than **FY 2008**, to display only fiscal year 2008.
7. Click OK.
8. Expand **FY 2008**, expand **H1 FY 2008**, and then expand **Q1 FY 2008**.

The following image shows a PivotTable for the Analysis Services Tutorial cube, with the Sales Quota measure group dimensioned correctly.

Notice that each member of the fiscal quarter level has the same value as the quarter level. Using **Q1 FY 2008** as an example, the quota of \$9,180,000.00 for **Q1 FY 2008** is also the value for each of its members. This behavior occurs because the grain of the data in the fact table is at the quarter level and the grain of the Date dimension is also at the quarter level. In Lesson 6, you will learn how to allocate the quarterly amount proportionally to each month.

The screenshot shows a Microsoft Excel window with the title "Book3 - Microsoft Excel". The ribbon at the top has tabs for File, Home, Insert, Page Layout, Formulas, Data, Review, View, Options, and Design. The Design tab is selected. The main area shows a PivotTable with data for Sales Amount Quota. The PivotTable Field List pane on the right shows fields from the Date dimension, including Date.Fiscal Date, which is selected. The PivotTable data is as follows:

| | A | B | C |
|----|--------------------|-----------------|-----------------|
| 1 | Sales Amount Quota | Column Labels | |
| 2 | Row Labels | North America | Grand Total |
| 3 | FY 2008 | \$28,715,000.00 | \$28,715,000.00 |
| 4 | H1 FY 2008 | \$16,366,000.00 | \$16,366,000.00 |
| 5 | Q1 FY 2008 | \$9,180,000.00 | \$9,180,000.00 |
| 6 | July 2007 | \$9,180,000.00 | \$9,180,000.00 |
| 7 | August 2007 | \$9,180,000.00 | \$9,180,000.00 |
| 8 | September 2007 | \$9,180,000.00 | \$9,180,000.00 |
| 9 | Q2 FY 2008 | \$7,186,000.00 | \$7,186,000.00 |
| 10 | | \$12,349,000.00 | \$12,349,000.00 |
| 11 | Grand Total | \$28,715,000.00 | \$28,715,000.00 |
| 12 | | | |
| 13 | | | |
| 14 | | | |
| 15 | | | |

[Work with Diagrams in Data Source View Designer \(Analysis Services\)](#)

Lesson 6: Defining Calculations

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In this lesson, you learn to define calculations, which are Multidimensional Expressions (MDX) expressions or scripts. Calculations enable you to define calculated members, named sets, and execute other script commands to extend the capabilities of an Analysis Services cube. For example, you can run a script command to define a subcube and then assign a calculation to the cells in the subcube.

When you define a new calculation in Cube Designer, the calculation is added to the **Script Organizer** pane of the **Calculations** tab of Cube Designer, and the fields for the particular calculation type are displayed in a calculations form in the **Calculation Expressions** pane. Calculations are executed in the order in which they are listed in the **Script Organizer** pane. You can reorder the calculations by right-clicking on a particular calculation and then selecting **Move Up** or **Move Down**, or by clicking a particular calculation and then using the **Move Up** or **Move Down** icons on the toolbar of the **Calculations** tab.

On the **Calculations** tab, you can add new calculations and view or edit existing calculations in the following views in the **Calculation Expressions** pane:

- Form view. This view shows the expressions and properties for a single command in a graphical format. When you edit an MDX script, an expression box fills the Form view.
- Script view. This view displays all calculation scripts in a code editor, which lets you easily change the calculation scripts. When the **Calculation Expressions** pane is in Script view, the **Script Organizer** is hidden. The Script view provides color coding, parenthesis matching, auto-complete, and MDX code regions. You can expand or collapse the MDX code regions to make editing easier.

To switch between these views in the **Calculation Expressions** pane, click **Form View** or **Script View** on the toolbar of the **Calculations** tab.

NOTE

If Analysis Services detects a syntax error in any calculation, the Form view will not display until the error is corrected in the Script view.

You can also use the Business Intelligence Wizard to add certain calculations to a cube. For example, you can use this wizard to add time intelligence to a cube, which means defining calculated members for time-related calculations such as period-to-date, moving averages, or period over period growth. For more information, see [Define Time Intelligence Calculations using the Business Intelligence Wizard](#).

IMPORTANT

On the **Calculations** tab, the calculation script starts with the CALCULATE command. The CALCULATE command controls the aggregation of the cells in the cube and you should edit this command only if you intend to manually specify how the cube cells should be aggregated.

For more information, see [Calculations](#), and [Calculations in Multidimensional Models](#).

NOTE

[Create Calculated Members](#)

Lesson 6-1 - Defining Calculated Members

7/16/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Calculated members are members of a dimension or a measure group that are defined based on a combination of cube data, arithmetic operators, numbers, and functions. For example, you can create a calculated member that calculates the sum of two physical measures in the cube. Calculated member definitions are stored in cubes, but their values are calculated at query time.

To create a calculated member, use the **New Calculated Member** command on the **Calculations** tab of Cube Designer. You can create a calculated member within any dimension, including the measures dimension. You can also place a calculated member within a display folder in the **Calculation Properties** dialog box. For more information, see [Calculations, Calculations in Multidimensional Models](#), and [Create Calculated Members](#).

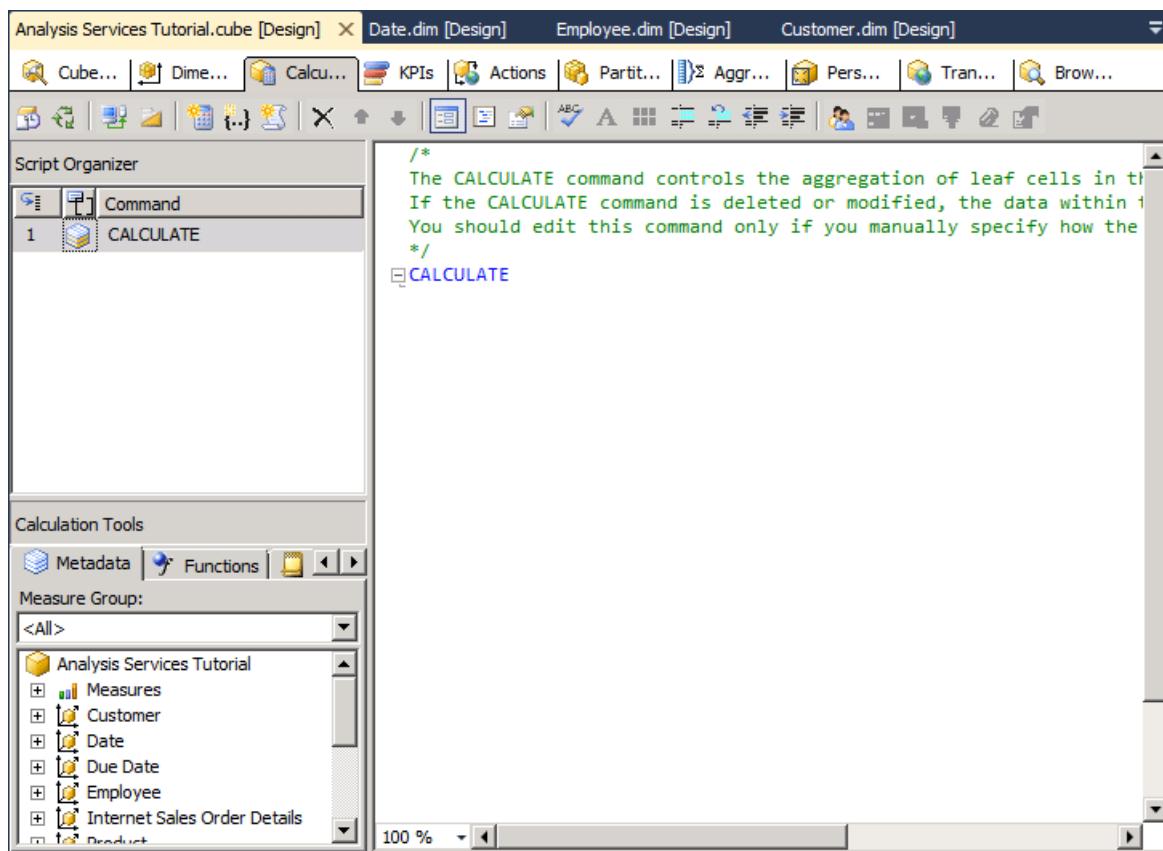

In the tasks in this topic, you define calculated measures to let users view the gross profit margin percentage and sales ratios for Internet sales, reseller sales, and for all sales.

Defining Calculations to Aggregate Physical Measures

1. Open Cube Designer for the Analysis Services Tutorial cube, and then click the **Calculations** tab.

Notice the default CALCULATE command in the **Calculation Expressions** pane and in the **Script Organizer** pane. This command specifies that the measures in the cube should be aggregated according to the value that is specified by their AggregateFunction properties. Measure values are generally summed, but may also be counted or aggregated in some other manner.

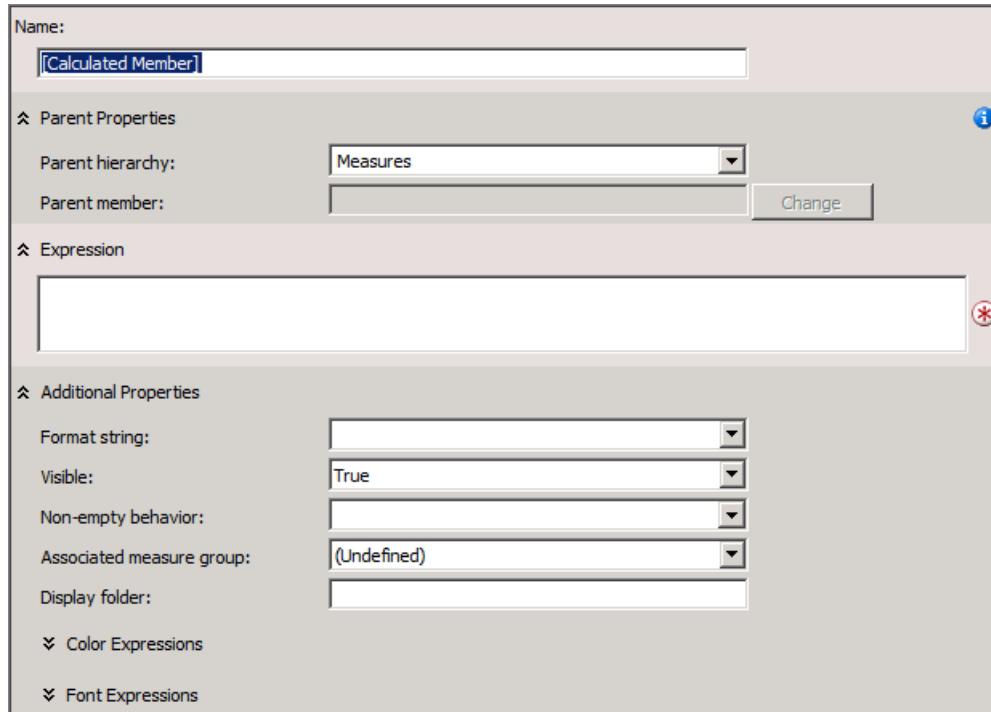

The following image shows the **Calculations** tab of Cube Designer.

2. On the toolbar of the **Calculations** tab, click **New Calculated Member**.

A new form appears in the **Calculation Expressions** pane within which you define the properties of this new calculated member. The new member also appears in the **Script Organizer** pane.

The following image shows the form that appears in the **Calculation Expressions** pane when you click **New Calculated Member**.

3. In the **Name** box, change the name of the calculated measure to **[Total Sales Amount]**.

If the name of a calculated member contains a space, the calculated member name must be enclosed in square brackets.

Notice in the **Parent hierarchy** list that, by default, a new calculated member is created in the **Measures** dimension. A calculated member in the Measures dimension is also frequently called a calculated measure.

4. On the **Metadata** tab in the **Calculation Tools** pane of the **Calculations** tab, expand **Measures** and then expand **Internet Sales** to view the metadata for the **Internet Sales** measure group.

You can drag metadata elements from the **Calculation Tools** pane into the **Expression** box and then add operators and other elements to create Multidimensional Expressions (MDX) expressions. Alternatively, you can type the MDX expression directly into the **Expression** box.

NOTE

If you cannot view any metadata in the **Calculation Tools** pane, click **Reconnect** on the toolbar. If this does not work, you may have to process the cube or start the instance of Analysis Services.

5. Drag **Internet Sales-Sales Amount** from the **Metadata** tab in the **Calculation Tools** pane into the **Expression** box in the **Calculation Expressions** pane.

6. In the **Expression** box, type a plus sign (+) after **[Measures].[Internet Sales-Sales Amount]**.

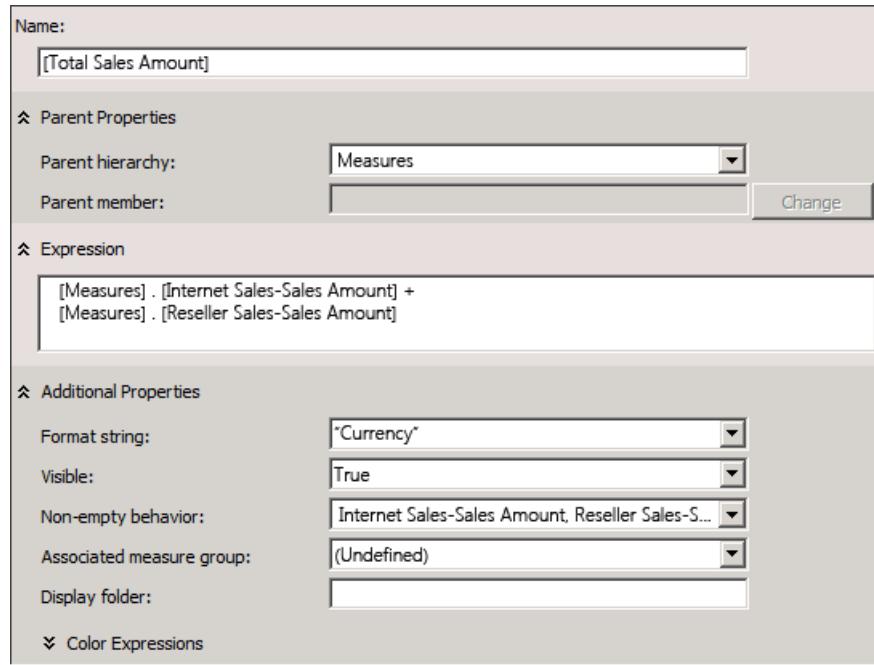

7. On the **Metadata** tab in the **Calculation Tools** pane, expand **Reseller Sales**, and then drag **Reseller Sales-Sales Amount** into the **Expression** box in the **Calculation Expressions** pane after the plus sign (+).

8. In the **Format string** list, select "**Currency**".

9. In the **Non-empty behavior** list, select the check boxes for **Internet Sales-Sales Amount** and **Reseller Sales-Sales Amount**, and then click **OK**.

The measures you specify in the **Non-empty behavior** list are used to resolve NON EMPTY queries in MDX. When you specify one or more measures in the **Non-empty behavior** list, Analysis Services treats the calculated member as empty if all the specified measures are empty. If the **Non-empty behavior** property is blank, Analysis Services must evaluate the calculated member itself to determine whether the member is empty.

The following image shows the **Calculation Expressions** pane populated with the settings that you specified in the previous steps.

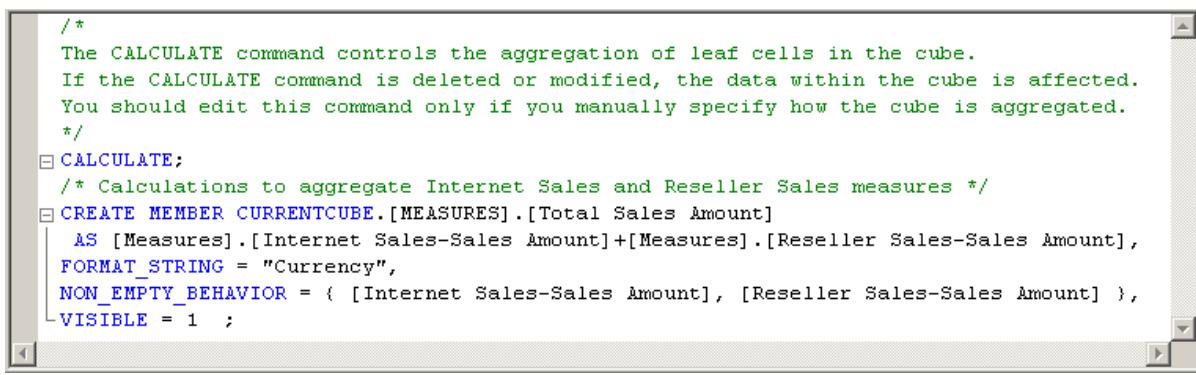

10. On the toolbar of the **Calculations** tab, click **Script View**, and then review the calculation script in the **Calculation Expressions** pane.

Notice that the new calculation is added to the initial CALCULATE expression; each individual calculation is separated by a semicolon. Notice also that a comment appears at the beginning of the calculation script. Adding comments within the calculation script for groups of calculations is a good practice, to help you and other developers understand complex calculation scripts.

11. Add a new line in the calculation script after the **Calculate;** command and before the newly added calculation script, and then add the following text to the script on its own line:

```
/* Calculations to aggregate Internet Sales and Reseller Sales measures */
```

The following image shows the calculation scripts as they should appear in the **Calculation Expressions** pane at this point in the tutorial.

```

/*
The CALCULATE command controls the aggregation of leaf cells in the cube.
If the CALCULATE command is deleted or modified, the data within the cube is affected.
You should edit this command only if you manually specify how the cube is aggregated.
*/
CALCULATE;
/* Calculations to aggregate Internet Sales and Reseller Sales measures */
CREATE MEMBER CURRENTCUBE.[MEASURES].[Total Sales Amount]
    AS [Measures].[Internet Sales-Sales Amount]+[Measures].[Reseller Sales-Sales Amount],
    FORMAT_STRING = "Currency",
    NON_EMPTY_BEHAVIOR = { [Internet Sales-Sales Amount], [Reseller Sales-Sales Amount] },
    VISIBLE = 1 ;

```

12. On the toolbar of the **Calculations** tab, click **Form View**, verify that **[Total Sales Amount]** is selected in the **Script Organizer** pane, and then click **New Calculated Member**.
13. Change the name of this new calculated member to **[Total Product Cost]**, and then create the following expression in the **Expression** box:

[Measures].[Internet Sales-Total Product Cost] + [Measures].[Reseller Sales-Total Product Cost]

14. In the **Format string** list, select **"Currency"**.
15. In the **Non-empty behavior** list, select the check boxes for **Internet Sales-Total Product Cost** and **Reseller Sales-Total Product Cost**, and then click **OK**.

You have now defined two calculated members, both of which are visible in the **Script Organizer** pane. These calculated members can be used by other calculations that you define later in the calculation script. You can view the definition of any calculated member by selecting the calculated member in the **Script Organizer** pane; the definition of the calculated member will appear in the **Calculation Expressions** pane in the Form view. Newly defined calculated members will not appear in the **Calculation Tools** pane until these objects have been deployed. Calculations do not require processing.

Defining Gross Profit Margin Calculations

1. Verify that **[Total Product Cost]** is selected in the **Script Organizer** pane, and then click **New Calculated Member** on the toolbar of the **Calculations** tab.
2. In the **Name** box, change the name of this new calculated measure to **[Internet GPM]**.
3. In the **Expression** box, create the following MDX expression:

([Measures].[Internet Sales-Sales Amount] -
 [Measures].[Internet Sales-Total Product Cost]) /
 [Measures].[Internet Sales-Sales Amount]

4. In the **Format string** list, select **"Percent"**.
5. In the **Non-empty behavior** list, select the check box for **Internet Sales-Sales Amount**, and then click **OK**.
6. On the toolbar of the **Calculations** tab, click **New Calculated Member**.
7. In the **Name** box, change the name of this new calculated measure to **[Reseller GPM]**.
8. In the **Expression** box, create the following MDX expression:

```
([Measures].[Reseller Sales-Sales Amount] -
[Measures].[Reseller Sales-Total Product Cost]) /
[Measures].[Reseller Sales-Sales Amount]
```

9. In the **Format string** list, select "**Percent**".
10. In the **Non-empty behavior** list, select the check box for **Reseller Sales-Sales Amount**, and then click **OK**.
11. On the toolbar of the **Calculations** tab, click **New Calculated Member**.
12. In the **Name** box, change the name of this calculated measure to **[Total GPM]**.
13. In the **Expression** box, create the following MDX expression:

```
([Measures].[Total Sales Amount] -
[Measures].[Total Product Cost]) /
[Measures].[Total Sales Amount]
```

Notice that this calculated member is referencing other calculated members. Because this calculated member will be calculated after the calculated members that it references, this is a valid calculated member.

14. In the **Format string** list, select "**Percent**".
15. In the **Non-empty behavior** list, select the check boxes for **Internet Sales-Sales Amount** and **Reseller Sales-Sales Amount**, and then click **OK**.
16. On the toolbar of the **Calculations** tab, click **Script View** and review the three calculations you just added to the calculation script.
17. Add a new line in the calculation script immediately before the **[Internet GPM]** calculation, and then add the following text to the script on its own line:

```
/* Calculations to calculate gross profit margin */
```

The following image shows the **Expressions** pane with the three new calculations.

```
/* Calculations to calculate gross profit margin */
CREATE MEMBER CURRENTCUBE.[MEASURES].[Internet GPM]
AS ([Measures].[Internet Sales-Sales Amount] -
[Measures].[Internet Sales-Total Product Cost]) /
[Measures].[Internet Sales-Sales Amount],
FORMAT_STRING = "Percent",
NON_EMPTY_BEHAVIOR = { [Internet Sales-Sales Amount] },
VISIBLE = 1 ;
CREATE MEMBER CURRENTCUBE.[MEASURES].[Reseller GPM]
AS ([Measures].[Reseller Sales-Sales Amount] -
[Measures].[Reseller Sales-Total Product Cost]) /
[Measures].[Reseller Sales-Sales Amount],
FORMAT_STRING = "Percent",
NON_EMPTY_BEHAVIOR = { [Reseller Sales-Sales Amount] },
VISIBLE = 1 ;
CREATE MEMBER CURRENTCUBE.[MEASURES].[Total GPM]
AS ([Measures].[Total Sales Amount] -
[Measures].[Total Product Cost]) /
[Measures].[Total Sales Amount],
FORMAT_STRING = "Percent",
NON_EMPTY_BEHAVIOR = { [Internet Sales-Sales Amount], [Reseller Sales-Sales Amount] },
VISIBLE = 1 ;
```

Defining the Percent of Total Calculations

1. On the toolbar of the **Calculations** tab, click **Form View**.
2. In the **Script Organizer** pane, select **[Total GPM]**, and then click **New Calculated Member** on the toolbar of the **Calculations** tab.

Clicking the final calculated member in the **Script Organizer** pane before you click **New Calculated Member** guarantees that the new calculated member will be entered at the end of the script. Scripts execute in the order that they appear in the **Script Organizer** pane.

3. Change the name of this new calculated member to **[Internet Sales Ratio to All Products]**.
4. Type the following expression in the **Expression** box:

```
Case
When IsEmpty( [Measures].[Internet Sales-Sales Amount] )
Then 0
Else ( [Product].[Product Categories].CurrentMember,
[Measures].[Internet Sales-Sales Amount]) /
([Product].[Product Categories].[All].[All],
[Measures].[Internet Sales-Sales Amount])
End
```

This MDX expression calculates the contribution to total Internet sales of each product. The Case statement together with the IS EMPTY function ensures that a divide by zero error does not occur when a product has no sales.

5. In the **Format string** list, select **"Percent"**.
6. In the **Non-empty behavior** list, select the check box for **Internet Sales-Sales Amount**, and then click **OK**.
7. On the toolbar of the **Calculations** tab, click **New Calculated Member**.
8. Change the name of this calculated member to **[Reseller Sales Ratio to All Products]**.
9. Type the following expression in the **Expression** box:

```
Case
When IsEmpty( [Measures].[Reseller Sales-Sales Amount] )
Then 0
Else ( [Product].[Product Categories].CurrentMember,
[Measures].[Reseller Sales-Sales Amount]) /
([Product].[Product Categories].[All].[All],
[Measures].[Reseller Sales-Sales Amount])
End
```

10. In the **Format string** list, select **"Percent"**.
11. In the **Non-empty behavior** list, select the check box for **Reseller Sales-Sales Amount**, and then click **OK**.
12. On the toolbar of the **Calculations** tab, click **New Calculated Member**.
13. Change the name of this calculated member to **[Total Sales Ratio to All Products]**.
14. Type the following expression in the **Expression** box:

```

Case
When IsEmpty( [Measures].[Total Sales Amount] )
Then 0
Else ( [Product].[Product Categories].CurrentMember,
[Measures].[Total Sales Amount]) /
([Product].[Product Categories].[(All)].[All],
[Measures].[Total Sales Amount] )
End

```

15. In the **Format string** list, select "**Percent**".
16. In the **Non-empty behavior** list, select the check boxes for **Internet Sales-Sales Amount** and **Reseller Sales-Sales Amount**, and then click **OK**.
17. On the toolbar of the **Calculations** tab, click **Script View**, and then review the three calculations that you just added to the calculation script.
18. Add a new line in the calculation script immediately before the **[Internet Sales Ratio to All Products]** calculation, and then add the following text to the script on its own line:

```
/* Calculations to calculate percentage of product to total product sales */
```

You have now defined a total of eight calculated members, which are visible in the **Script Organizer** pane when you are in Form view.

Browsing the New Calculated Members

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to the **Browser** tab, click **Reconnect**.
3. Click the Excel icon, and then click **Enable**.
4. In the **PivotTable Field List** pane, expand **Values** folder to view the new calculated members in the Measures dimension.
5. Drag the **Total Sales Amount** to the Values area, and then review the results.

Drag **Internet Sales-Sales Amount** and **Reseller Sales-Sales Amount** measures from the **Internet Sales** and **Reseller Sales** measure groups to the Values area.

Notice that the **Total Sales Amount** measure is the sum of the **Internet Sales-Sales Amount** measure and the **Reseller Sales-Sales Amount** measure.

6. Add the **Product Categories** user-defined hierarchy to the filter area of the **Report Filter** area, and then filter the data by **Mountain Bikes**.

Notice that the **Total Sales Amount** measure is calculated for the **Mountain Bikes** category of product sales based on the **Internet Sales-Sales Amount** and the **Reseller Sales-Sales Amount** measures for **Mountain Bikes**.

7. Add the **Date.Calendar Date** user-defined hierarchy to the Row labels area, and then review the results.

Notice that the **Total Sales Amount** measure for each calendar year is calculated for the **Mountain Bikes** category of product sales based on the **Internet Sales-Sales Amount** and the **Reseller Sales-Sales Amount** measures for **Mountain Bikes**.

8. Add the **Total GPM**, **Internet GPM**, and **Reseller GPM** measures to the Values area, and then review the

results.

Notice that the gross profit margin for reseller sales is significantly lower than for sales over the Internet, as shown in the following image.

| | A | B | C | D | E | F | G |
|---|----------------|-------------------|-------------------|--------------------|-----------|--------------|--------------|
| 1 | Product Catege | Mountain Bike | | | | | |
| 2 | | | | | | | |
| 3 | Row Labels | Total Sales Amoun | Internet Sales-Sa | Reseller Sales-Sal | Total GPM | Internet GPM | Reseller GPM |
| 4 | + CY 2005 | \$ 5,090,709.90 | \$543,373.39 | \$4,545,336.51 | 10.09% | 43.76% | 6.05% |
| 5 | + CY 2006 | \$10,707,430.82 | \$1,516,592.73 | \$9,190,838.09 | 7.30% | 44.84% | 1.10% |
| 6 | + CY 2007 | \$12,690,644.77 | \$3,836,381.73 | \$8,854,263.03 | 20.13% | 45.68% | 9.06% |
| 7 | + CY 2008 | \$7,956,658.45 | \$4,054,411.71 | \$3,902,246.74 | 26.18% | 45.45% | 6.17% |
| 8 | Grand Total | \$36,445,443.94 | \$9,952,759.56 | \$26,492,684.38 | 16.28% | 45.35% | 5.36% |

9. Add the **Total Sales Ratio to All Products**, **Internet Sales Ratio to All Products**, and **Reseller Sales Ratio to All Products** measures to the Values area.

Notice that the ratio of the sales of mountain bikes to all products has increased over time for Internet sales, but is decreasing over time for reseller sales. Notice also that the ratio of the sale of mountain bikes to all products is lower from sales through resellers than it is for sales over the Internet.

10. Change the filter from **Mountain Bikes** to **Bikes**, and review the results.

Notice that the gross profit margin for all bikes sold through resellers is negative, because touring bikes and road bikes are being sold at a loss.

11. Change the filter to **Accessories**, and then review the results.

Notice that the sale of accessories is increasing over time, but that these sales make up only a small fraction of total sales. Notice also that the gross profit margin for sales of accessories is higher than for bikes.

Next Task in Lesson

[Defining Named Sets](#)

[Calculations](#)

[Calculations in Multidimensional Models](#)

[Create Calculated Members](#)

Lesson 6-2 - Defining Named Sets

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A named set is a Multidimensional Expressions (MDX) expression that returns a set of dimension members. You can define named sets and save them as part of the cube definition; you can also create named sets in client applications. You create named sets by combining cube data, arithmetic operators, numbers, and functions. Named sets can be used by users in MDX queries in client applications and can also be used to define sets in subcubes. A subcube is a collection of crossjoined sets that restricts the cube space to the defined subspace for subsequent statements. Defining a restricted cube space is a fundamental concept to MDX scripting.

Named sets simplify MDX queries and provide useful aliases for complex, typically used, set expressions. For example, you can define a named set called Large Resellers that contains the set of members in the Reseller dimension that have the most employees. End users could then use the Large Resellers named set in queries, or you could use the named set to define a set in a subcube. Named set definitions are stored in cubes, but their values exist only in memory. To create a named set, use the **New Named Set** command on the **Calculations** tab of Cube Designer. For more information, see [Calculations](#), [Create Named Sets](#).

In the tasks in this topic, you will define two named sets: a Core Products named set and a Large Resellers named set.

Defining a Core Products Named Set

1. Switch to the **Calculations** tab of Cube Designer for the Analysis Services Tutorial cube, and then click **Form View** on the toolbar.
2. Click **[Total Sales Ratio to All Products]** in the **Script Organizer** pane, and then click **New Named Set** on the toolbar of the **Calculations** tab.

When you define a new calculation on the **Calculations** tab, remember that calculations are resolved in the order in which they appear in the **Script Organizer** pane. Your focus within that pane when you create a new calculation determines the order of the execution of the calculation; a new calculation is defined immediately after the calculation on which you are focused.

3. In the **Name** box, change the name of the new named set to **[Core Products]**.

In the **Script Organizer** pane, notice the unique icon that differentiates a named set from a script command or a calculated member.

4. On the **Metadata** tab in the **Calculation Tools** pane, expand **Product**, expand **Category**, expand **Members**, and then expand **All Products**.

NOTE

If you cannot view any metadata in the **Calculation Tools** pane, click **Reconnect** on the toolbar. If this does not work, you may have to process the cube or start the instance of Analysis Services.

5. Drag **Bikes** into the **Expression** box.

You now have created a set expression that will return the set of members that are in the Bike category in the Product dimension.

Defining a Large Resellers Named Set

1. Right-click **[Core Products]** in the **Script Organizer** pane, and then click **New Named Set**.
2. In the **Name** box, change the name of this named set to **[Large Resellers]**.
3. In the **Expression** box, type **Exists()**.

You will use the Exists function to return the set of members from the Reseller Name attribute hierarchy that intersects with the set of members in the Number of Employees attribute hierarchy that has the largest number of employees.

4. On the **Metadata** tab in the **Calculation Tools** pane, expand the **Reseller** dimension, and then expand the **Reseller Name** attribute hierarchy.
5. Drag the **Reseller Name** level into the parenthesis for the Exists set expression.

You will use the Members function to return all members of this set. For more information, see [Members \(Set\) \(MDX\)](#).

6. After the partial set expression, type a period, and then add the Members function. Your expression should look like the following:

```
Exists([Reseller].[Reseller Name].[Reseller Name].Members)
```

Now that you have defined the first set for the Exists set expression, you are ready to add the second set—the set of members of the Reseller dimension that contains the largest number of employees.

7. On the **Metadata** tab in the **Calculation Tools** pane, expand **Number of Employees** in the Reseller dimension, expand **Members**, and then expand **All Resellers**.

Notice that the members of this attribute hierarchy are not grouped.

8. Open Dimension Designer for the **Reseller** dimension, and then click **Number of Employees** in the **Attributes** pane.
9. In the Properties window, change the **DiscretizationMethod** property to **Automatic**, and then change the **DiscretizationBucketCount** property to **5**. For more information, see [Group Attribute Members \(Discretization\)](#).
10. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
11. When deployment has successfully completed, switch to Cube Designer for the Analysis Services Tutorial cube, and then click **Reconnect** on the toolbar of the **Calculations** tab.
12. On the **Metadata** tab in the **Calculation Tools** pane, expand **Number of Employees** in the **Reseller** dimension, expand **Members**, and then expand **All Resellers**.

Notice that the members of this attribute hierarchy are now contained in five groups, numbered 0 through

4. To view the number of a group, pause the pointer over that group to view an InfoTip. For the range **2 - 17**, the InfoTip should contain **[Reseller].[Number of Employees].&[0]**.

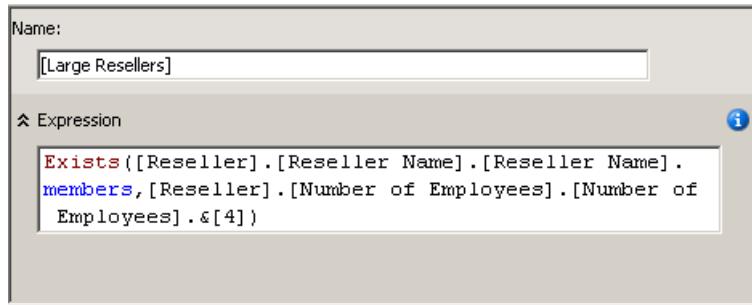

The members of this attribute hierarchy are grouped because the DiscretizationBucketCount property is set to **5** and the DiscretizationMethod property is set to **Automatic**.

13. In the **Expression** box, add a comma in the Exists set expression after the Members function and before the closing parenthesis, and then drag **83 - 100** from the **Metadata** pane and position it after the comma.

You have now completed the Exists set expression that will return the set of members that intersects with

these two specified sets, the set of all resellers and the set of resellers who have 83 to 100 employees, when the Large Resellers named set is put on an axis.

The following image shows the **Calculation Expressions** pane for the **[Large Resellers]** named set.

14. On the toolbar of the **Calculations** tab, click **Script View**, and then review the two named sets that you have just added to the calculation script.
15. Add a new line in the calculation script immediately before the first CREATE SET command, and then add the following text to the script on its own line:

```
/* named sets */
```

You have now defined two named sets, which are visible in the **Script Organizer** pane. You are now ready to deploy these named sets, and then to browse these measures in the Analysis Services Tutorial cube.

Browsing the Cube by Using the New Named Sets

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab, and then click **Reconnect**.
3. Clear the grid in the data pane.
4. Add the **Reseller Sales-Sales Amount** measure to the data area.
5. Expand the Product dimension, and then add Category and Subcategory to the row area, as shown in the following image.

| Dimension | Hierarchy | Operator | Filter Expression |
|--------------------|-------------------|-------------------|-------------------|
| <Select dimension> | | | |
| | | | |
| Category | Subcategory | Reseller Sales... | |
| Accessories | Bike Racks | 197736.156 | |
| Accessories | Bottles and Cages | 7476.603599... | |
| Accessories | Cleaners | 11188.3725 | |
| Accessories | Helmets | 258712.9323... | |
| Accessories | Hydration Packs | 65518.74850... | |
| Accessories | Locks | 16225.22 | |
| Accessories | Pumps | 13514.6873 | |
| Accessories | Tires and Tubes | 925.2076 | |
| Bikes | Mountain Bikes | 26492684.37... | |
| Bikes | Road Bikes | 29358206.96... | |
| Bikes | Touring Bikes | 10451490.21... | |
| Clothing | Bib-Shorts | 166739.7086... | |
| Clothing | Caps | 31541.34610... | |
| Clothing | Gloves | 207775.1742... | |
| Clothing | Jerseys | 579308.7083... | |

6. In the **Metadata** pane, in the **Product** dimension, drag **Core Products** to the filter area.

Notice that only the **Bike** member of the **Category** attribute and members of the **Bike** subcategories remain in the cube. This is because the **Core Products** named set is used to define a subcube. This subcube limits the members of the **Category** attribute in the **Product** dimension within the subcube to those members of the **Core Product** named set, as shown in the following image.

| Dimension | Hierarchy | Operator | Filter Expression |
|--------------------|----------------|-------------------|-------------------|
| <Select dimension> | | | |
|
 | | | |
| Product | Category | In | Core Products |
| <Select dimension> | | | |
| Category | Subcategory | Reseller Sales... | |
| Bikes | Mountain Bikes | 26492684.37... | |
| Bikes | Road Bikes | 29358206.96... | |
| Bikes | Touring Bikes | 10451490.21... | |

7. In the **Metadata** pane, expand **Reseller**, add **Large Resellers** to the filter area.

Notice that the Reseller Sales Amount measure in the Data pane only displays sales amounts for large resellers of bikes. Notice also that the Filter pane now displays the two named sets that are used to define this particular subcube, as shown in the following image.

| Dimension | Hierarchy | Operator | Filter Expression |
|--------------------|----------------|-------------------|-------------------|
| <Select dimension> | | | |
|
 | | | |
| Product | Category | In | Core Products |
| Reseller | Reseller Name | In | Large Resellers |
| <Select dimension> | | | |
| Category | Subcategory | Reseller Sales... | |
| Bikes | Mountain Bikes | 5748640.5721 | |
| Bikes | Road Bikes | 6985271.3659 | |
| Bikes | Touring Bikes | 3357480.2444 | |

Lesson 7: Defining Key Performance Indicators (KPIs)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In this lesson, you learn to define Key Performance Indicators (KPIs) in your Analysis Services project. KPIs provide a framework for defining server-side calculations that measure your business, and they standardize how the resulting information is displayed. KPIs can be displayed in reports, portals, and dashboards, through data access APIs, and through Microsoft tools and third-party tools. KPIs are metadata wrappers around regular measures and other Multidimensional Expressions (MDX) expressions. For more information, see [Key Performance Indicators \(KPIs\) in Multidimensional Models](#).

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

This lesson contains the following task:

[Defining and Browsing KPIs](#)

In this task, you define KPIs in the Form view and then switch to the Browser view to browse the cube data by using the KPIs.

[Key Performance Indicators \(KPIs\) in Multidimensional Models](#)

Lesson 7-1 - Defining and Browsing KPIs

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

To define key performance indicators (KPIs), you first define a KPI name and the measure group to which the KPI is associated. A KPI can be associated with all measure groups or with a single measure group. You then define the following elements of the KPI:

- The value expression

A value expression is a physical measure such as Sales, a calculated measure such as Profit, or a calculation that is defined within the KPI by using a Multidimensional Expressions (MDX) expression.

- The goal expression

A goal expression is a value, or an MDX expression that resolves to a value, that defines the target for the measure that the value expression defines. For example, a goal expression could be the amount by which the business managers of a company want to increase sales or profit.

- The status expression

A status expression is an MDX expression that Analysis Services uses to evaluate the current status of the value expression compared to the goal expression. A goal expression is a normalized value in the range of -1 to +1, where -1 is very bad, and +1 is very good. The status expression displays a graphic to help you easily determine the status of the value expression compared to the goal expression.

- The trend expression

A trend expression is an MDX expression that Analysis Services uses to evaluate the current trend of the value expression compared to the goal expression. The trend expression helps the business user to quickly determine whether the value expression is becoming better or worse relative to the goal expression. You can associate one of several graphics with the trend expression to help business users be able to quickly understand the trend.

In addition to these elements that you define for a KPI, you also define several properties of a KPI. These properties include a display folder, a parent KPI if the KPI is computed from other KPIs, the current time member if there is one, the weight of the KPI if it has one, and a description of the KPI.

NOTE

For more examples of KPIs, see the KPI examples on the Templates tab in the Calculation Tools pane or in the examples in the **Adventure Works DW 2012** sample data warehouse. For more information about how to install this database, see [Install Sample Data and Projects for the Analysis Services Multidimensional Modeling Tutorial](#).

In the task in this lesson, you define KPIs in the Analysis Services Tutorial project, and you then browse the Analysis Services Tutorial cube by using these KPIs. You will define the following KPIs:

- Reseller Revenue

This KPI is used to measure how actual reseller sales compare to sales quotas for reseller sales, how close the sales are to the goal, and what the trend is toward reaching the goal.

- Product Gross Profit Margin

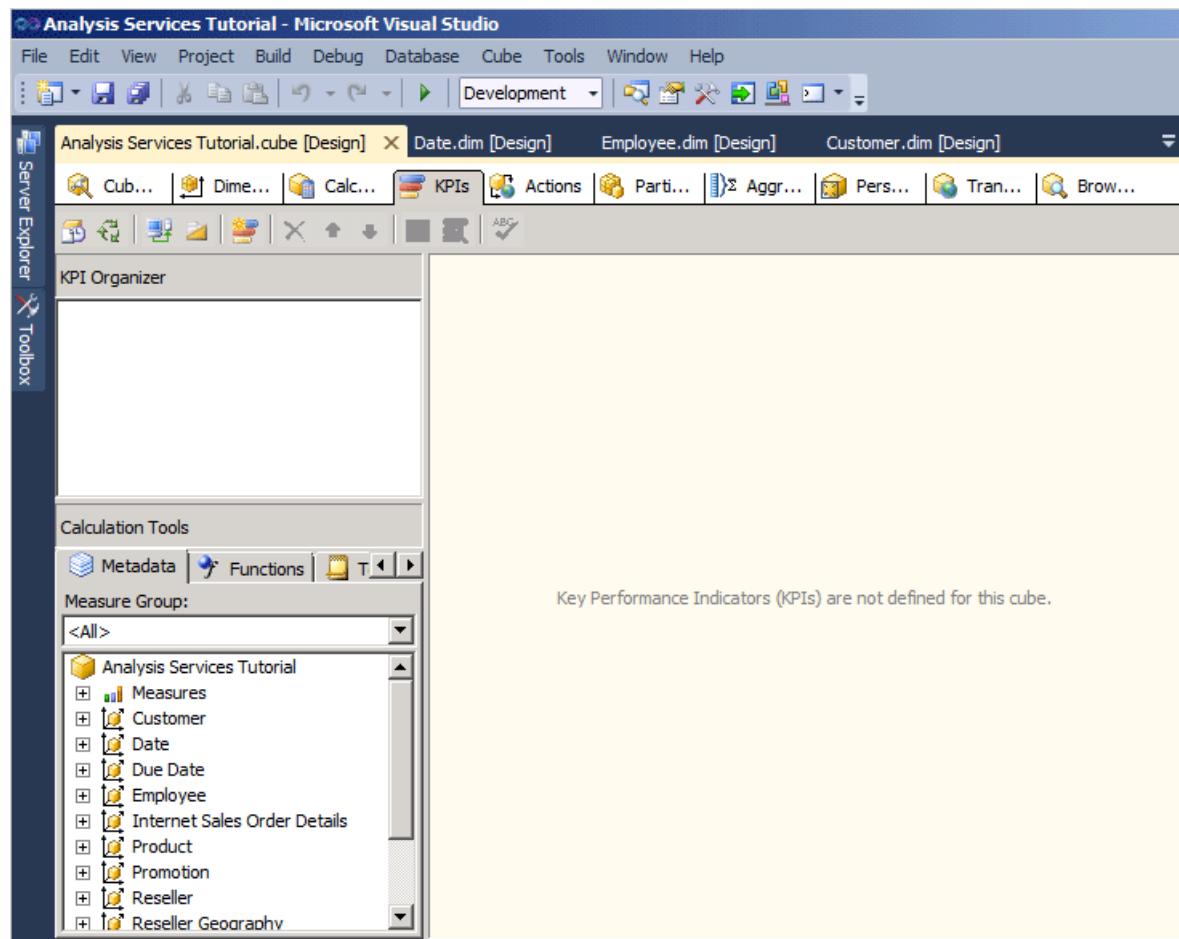

This KPI is used to determine how close the gross profit margin is for each product category to a specified goal for each product category, and also to determine the trend toward reaching this goal.

Defining the Reseller Revenue KPI

1. Open Cube Designer for the Analysis Services Tutorial cube, and then click the **KPIs** tab.

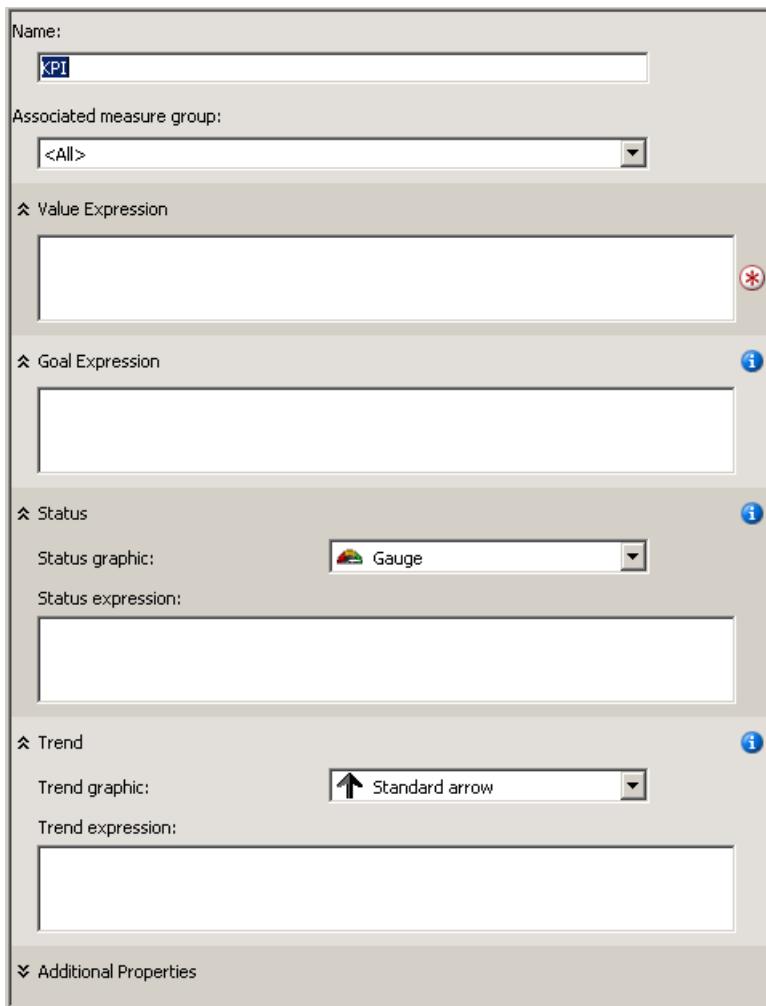

The **KPIs** tab includes several panes. On the left side of the tab are the **KPI Organizer** pane and the **Calculation Tools** pane. The display pane in the middle of the tab contains the details of the KPI that is selected in the **KPI Organizer** pane.

The following image shows the **KPIs** tab of Cube Designer.

2. On the toolbar of the **KPIs** tab, click the **New KPI** button.

A blank KPI template appears in the display pane, as shown in the following image.

3. In the **Name** box, type **Reseller Revenue**, and then select **Reseller Sales** in the **Associated measure group** list.
4. On the **Metadata** tab in the **Calculation Tools** pane, expand **Measures**, expand **Reseller Sales**, and then drag the **Reseller Sales-Sales Amount** measure to the **Value Expression** box.
5. On the **Metadata** tab in the **Calculation Tools** pane, expand **Measures**, expand **Sales Quotas**, and then drag the **Sales Amount Quota** measure to the **Goal Expression** box.
6. Verify that **Gauge** is selected in the **Status indicator** list, and then type the following MDX expression in the **Status expression** box:

```

Case
When
    KpiValue("Reseller Revenue")/KpiGoal("Reseller Revenue")>=.95
        Then 1
    When
        KpiValue("Reseller Revenue")/KpiGoal("Reseller Revenue")<.95
            And
                KpiValue("Reseller Revenue")/KpiGoal("Reseller Revenue")>=.85
                    Then 0
                Else-1
            End
        End
    End

```

This MDX expression provides the basis for evaluating the progress toward the goal. In this MDX expression, if actual reseller sales are more than 85 percent of the goal, a value of 0 is used to populate the chosen graphic. Because a gauge is the chosen graphic, the pointer in the gauge will be half-way between empty and full. If actual reseller sales are more the 90 percent, the pointer on the gauge will be three-fourths of the way between empty and full.

7. Verify that **Standard arrow** is selected in the **Trend indicator** list, and then type the following expression in the **Trend expression** box:

```
Case
When IsEmpty
  (ParallelPeriod
    ([Date].[Calendar Date].[Calendar Year],1,
     [Date].[Calendar Date].CurrentMember))
Then 0
When (
  KpiValue("Reseller Revenue") -
  (KpiValue("Reseller Revenue"),
   ParallelPeriod
     ([Date].[Calendar Date].[Calendar Year],1,
      [Date].[Calendar Date].CurrentMember))
  /
  (KpiValue ("Reseller Revenue"),
   ParallelPeriod
     ([Date].[Calendar Date].[Calendar Year],1,
      [Date].[Calendar Date].CurrentMember)))
  >=.02
Then 1
When(
  KpiValue("Reseller Revenue") -
  (KpiValue ("Reseller Revenue" ),
   ParallelPeriod
     ([Date].[Calendar Date].[Calendar Year],1,
      [Date].[Calendar Date].CurrentMember))
  /
  (KpiValue("Reseller Revenue"),
   ParallelPeriod
     ([Date].[Calendar Date].[Calendar Year],1,
      [Date].[Calendar Date].CurrentMember)))
  <=.02
Then -1
Else 0
End
```

This MDX expression provides the basis for evaluating the trend toward achieving the defined goal.

Browsing the Cube by Using the Reseller Revenue KPI

1. On the **Build** menu of Visual Studio with Analysis Services projects, click **Deploy Analysis Service Tutorial**.
2. When deployment has successfully completed, on the toolbar of the **KPIs** tab, click the **Browser View** button, and then click **Reconnect**.

The status and trend gauges are displayed in the **KPI Browser** pane for reseller sales based on the values for the default member of each dimension, together with the value for the value and the goal. The default member of each dimension is the All member of the All level, because you have not defined any other member of any dimension as the default member.
3. In the filter pane, select **Sales Territory** in the **Dimension** list, select **Sales Territories** in the **Hierarchy** list, select **Equal** in the **Operator** list, select the **North America** check box in the **Filter Expression** list, and then click **OK**.
4. In the next row in the **Filter** pane, select **Date** in the **Dimension** list, select **Calendar Date** in the **Hierarchy** list, select **Equal** in the **Operator** list, select the **Q3 CY 2007** check box in the **Filter Expression** list, and then click **OK**.
5. Click anywhere in the **KPI Browser** pane to update the values for the **Reseller Revenue KPI**.

Notice that the **Value**, **Goal**, and **Status** sections of the KPI reflect the values for the new time period.

Defining the Product Gross Profit Margin KPI

1. Click the **Form View** button on the toolbar of the **KPIs** tab, and then click the **New KPI** button.
2. In the **Name** box, type **Product Gross Profit Margin**, and then verify that appears in the **Associated measure group** list.
3. In the **Metadata** tab in the **Calculation Tools** pane, drag the **Total GPM** measure to the **Value Expression** box.
4. In the **Goal Expression** box, type the following expression:

```
Case
When [Product].[Category].CurrentMember Is
    [Product].[Category].[Accessories]
Then .40
When [Product].[Category].CurrentMember
    Is [Product].[Category].[Bikes]
Then .12
When [Product].[Category].CurrentMember Is
    [Product].[Category].[Clothing]
Then .20
When [Product].[Category].CurrentMember Is
    [Product].[Category].[Components]
Then .10
Else .12
End
```

5. In the **Status indicator** list, select **Cylinder**.
6. Type the following MDX expression in the **Status expression** box:

```
Case
When KpiValue( "Product Gross Profit Margin" ) /
    KpiGoal ( "Product Gross Profit Margin" ) >= .90
Then 1
When KpiValue( "Product Gross Profit Margin" ) /
    KpiGoal ( "Product Gross Profit Margin" ) < .90
    And
        KpiValue( "Product Gross Profit Margin" ) /
        KpiGoal ( "Product Gross Profit Margin" ) >= .80
Then 0
Else -1
End
```

This MDX expression provides the basis for evaluating the progress toward the goal.

7. Verify that **Standard arrow** is selected in the **Trend indicator** list, and then type the following MDX expression in the **Trend expression** box:

```

Case
When IsEmpty
  (ParallelPeriod
    ([Date].[Calendar Date].[Calendar Year],1,
     [Date].[Calendar Date].CurrentMember))
Then 0
When VBA!Abs
(
  KpiValue( "Product Gross Profit Margin" ) -
  (
    KpiValue ( "Product Gross Profit Margin" ),
    ParallelPeriod
    (
      [Date].[ Calendar Date].[ Calendar Year],
      1,
      [Date].[ Calendar Date].CurrentMember
    )
  ) /
  (
    KpiValue ( "Product Gross Profit Margin" ),
    ParallelPeriod
    (
      [Date].[ Calendar Date].[ Calendar Year],
      1,
      [Date].[ Calendar Date].CurrentMember
    )
  )
)
) <=.02
Then 0
When KpiValue( "Product Gross Profit Margin" ) -
(
  KpiValue ( "Product Gross Profit Margin" ),
  ParallelPeriod
  (
    [Date].[ Calendar Date].[ Calendar Year],
    1,
    [Date].[ Calendar Date].CurrentMember
  )
) /
(
  KpiValue ( "Product Gross Profit Margin" ),
  ParallelPeriod
  (
    [Date].[Calendar Date].[Calendar Year],
    1,
    [Date].[Calendar Date].CurrentMember
  )
)
) >.02
Then 1
Else -1
End

```

This MDX expression provides the basis for evaluating the trend toward achieving the defined goal.

Browsing the Cube by Using the Total Gross Profit Margin KPI

1. On the **Build** menu, click **Deploy Analysis Service Tutorial**.
2. When deployment has successfully completed, click **Reconnect** on the toolbar of the **KPIs** tab, and then click **Browser View**.

The **Product Gross Profit Margin** KPI appears and displays the KPI value for **Q3 CY 2007** and the **North America** sales territory.

3. In the **Filter** pane, select **Product** in the **Dimension** list, select **Category** in the **Hierarchy** list, select

Equal in the **Operator** list, and then select **Bikes** in the **Filter Expression** list, and then click **OK**.

The gross profit margin for the sale of Bikes by resellers in North America in Q3 CY 2007 appears.

[Lesson 8: Defining Actions](#)

Lesson 8: Defining Actions

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In this lesson, you will learn to define actions in your Analysis Services project. An action is just a Multidimensional Expressions (MDX) statement that is stored in Analysis Services and which can be incorporated into client applications and started by a user.

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

Analysis Services supports the types of actions that are described in the following table.

| | |
|--------------|--|
| CommandLine | Executes a command at the command prompt |
| Dataset | Returns a dataset to a client application. |
| Drillthrough | Returns a drillthrough statement as an expression, which the client executes to return a rowset |
| Html | Executes an HTML script in an Internet browser |
| Proprietary | Performs an operation by using an interface other than those listed in this table. |
| Report | Submits a parameterized URL-based request to a report server and returns a report to a client application. |
| Rowset | Returns a rowset to a client application. |
| Statement | Runs an OLE DB command. |
| URL | Displays a dynamic Web page in an Internet browser. |

Actions let users start an application or perform other steps within the context of a selected item. For more information, see [Actions \(Analysis Services - Multidimensional Data\)](#), [Actions in Multidimensional Models](#)

NOTE

For examples of actions, see the action examples on the Templates tab in the Calculation Tools pane or in the examples in the Adventure Works DW sample data warehouse. For more information about installing this database, see [Install Sample Data and Projects for the Analysis Services Multidimensional Modeling Tutorial](#).

This lesson includes the following task:

[Defining and Using a Drillthrough Action](#)

In this task, you define, use, and then modify a drillthrough action through the fact dimension relationship that you defined earlier in this tutorial.

Next Lesson

[Lesson 9: Defining Perspectives and Translations](#)

Lesson 8-1 - Defining and Using a Drillthrough Action

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Dimensioning fact data by a fact dimension without correctly filtering the data that the query returns can cause slow query performance. To avoid this, you can define a drillthrough action that restricts the total number of rows that are returned. This will significantly improve query performance.

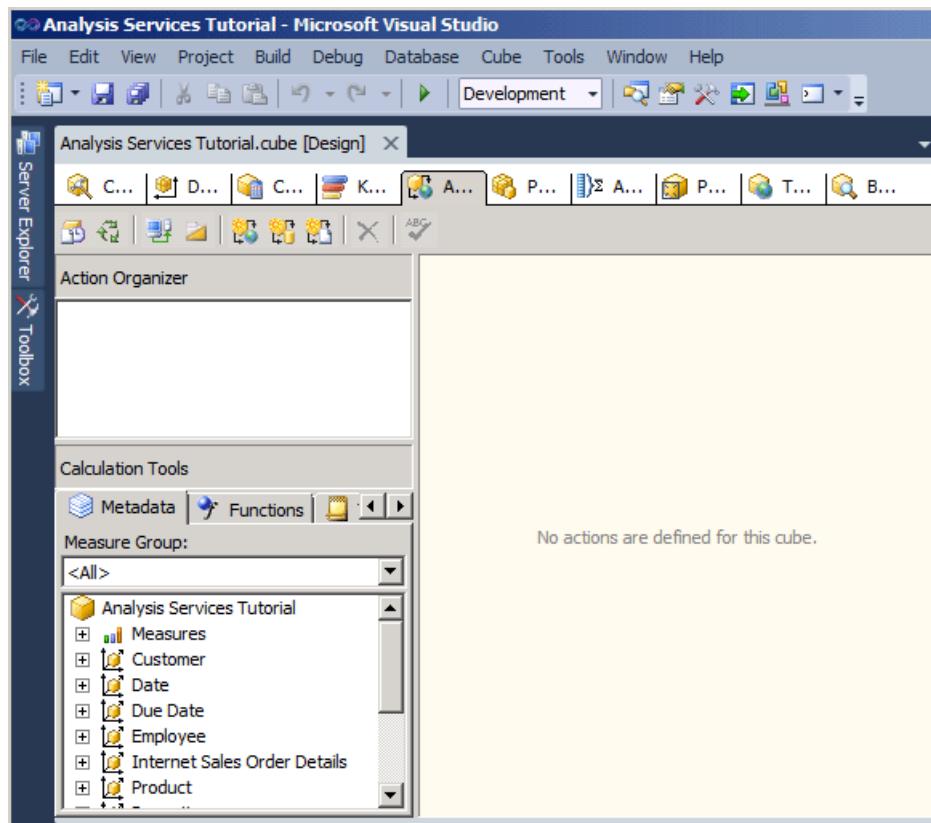

In the tasks in this topic, you define a drillthrough action to return order detail information for sales to customers over the Internet.

Defining the Drillthrough Action Properties

1. In Cube Designer for the Analysis Services Tutorial cube, click the **Actions** tab.

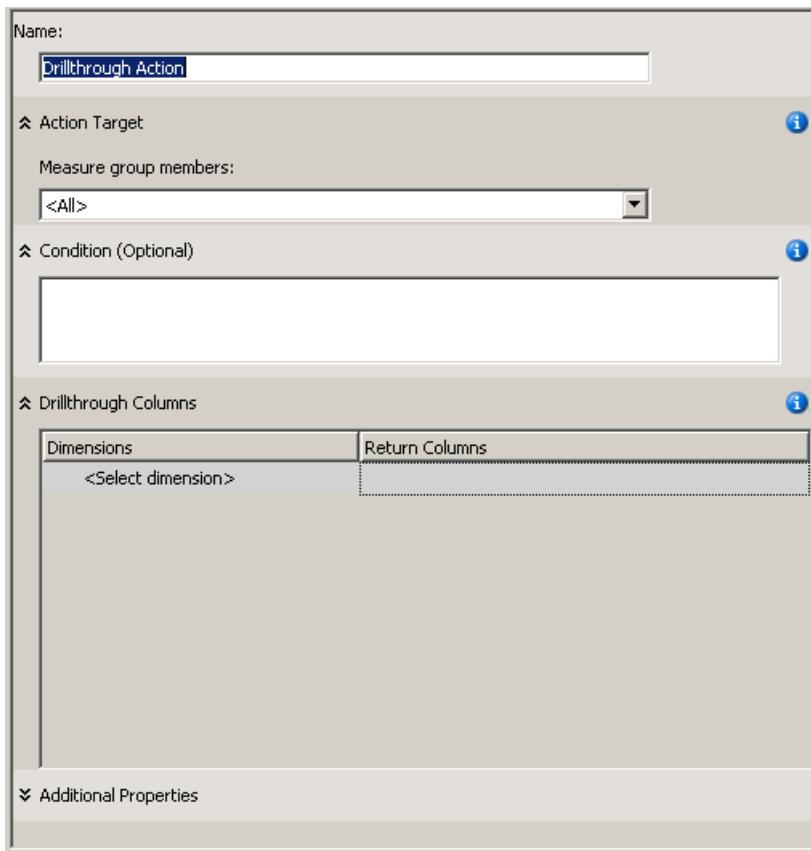

The **Actions** tab includes several panes. On the left side of the tab are the **Action Organizer** pane and the **Calculation Tools** pane. The pane to the right of these two panes is the **Display** pane, which contains the details of the action that is selected in the **Action Organizer** pane.

The following image shows the **Actions** tab of Cube Designer.

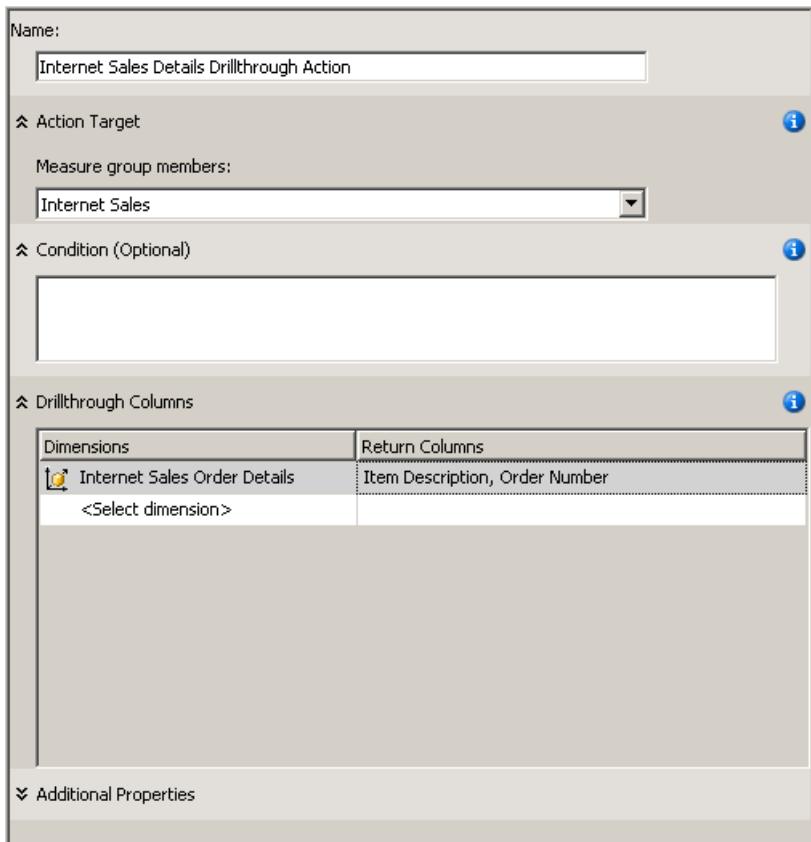

2. On the toolbar of the **Actions** tab, click the **New Drillthrough Action** button.

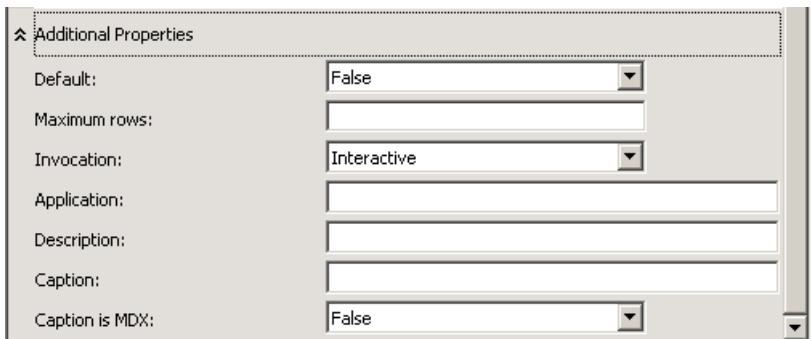

A blank action template appears in the display pane.

3. In the **Name** box, change the name of this action to **Internet Sales Details Drillthrough Action**.
4. In the **Measure group members** list, select **Internet Sales**.
5. In the **Drillthrough Columns** box, select **Internet Sales Order Details** in the **Dimensions** list.
6. In the **Return Columns** list, select the **Item Description** and the **Order Number** check boxes, and then click **OK**. The following image shows the Action template as it should appear at this point in this procedure.

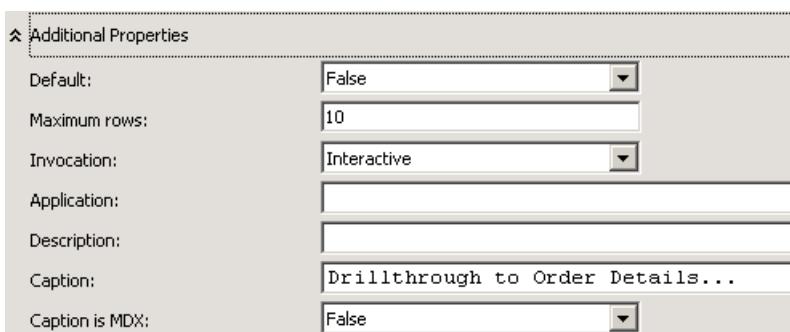

7. Expand the **Additional Properties** box, as shown in the following image.

8. In the **Maximum Rows** box, type **10**.
9. In the **Caption** box, type **Drillthrough to Order Details...**

These settings limit the number of rows returned and specify the caption that appears in the client application menu. The following image shows these settings in the **AdditionalProperties** box.

Using the Drillthrough Action

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, click the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click the **Reconnect** button.
3. Start Excel.
4. Add the **Internet Sales-Sales Amount** measure to the Values area.
5. Add the **Customer Geography** user-defined hierarchy from the **Location** folder in the **Customer** dimension to the **Report Filter** area.
6. On the PivotTable, in **Customer Geography**, add a filter that selects a single customer. Expand **All Customers**, expand **Australia**, expand **Queensland**, expand **Brisbane**, expand **4000**, select the check box for **Adam Powell**, and then click **OK**.

The total sales of products by Adventure Works Cycles to Adam Powell are displayed in the data area.

7. Right-click on the sales amount, point to **Additional Actions**, and then click **Drillthrough to Order Details**.

The details of the orders that were shipped to Adam Powell are displayed in the **Data Sample Viewer**, as shown in the following image. However, some additional details would also be useful, such as the order date, due date, and ship date. In the next procedure, you will add these additional details.

| | |
|--|---|
| Data returned for 'Internet Sales Details Drillthrough | Action' ([Customer].[Customer Geography].[Full N: |
| [\$Internet Sales Order Detail].[Item Description] | [\$Internet Sales Order Details].[Order Number] |
| Road-250 Black, 48 | SO49206 |
| Road-350W Yellow, 48 | SO61522 |
| Short-Sleeve Classic Jersey, XL | SO6152 |

8. Close Excel/

Modifying the Drillthrough Action

1. Open Dimension Designer for the **Internet Sales Order Details** dimension.

Notice that only three attributes have been defined for this dimension.

2. In the **Data Source View** pane, right-click an open area, and then click **Show All Tables**.

3. On the **Format** menu, point to **Autolayout** and then click **Diagram**.

4. Locate the **InternetSales (dbo.FactInternetSales)** table by right-clicking in an open area of the **Data Source View** pane. Then click **Find Table**, click **InternetSales**, and click **OK**.

5. Create new attributes based on the following columns:

- OrderDateKey
- DueDateKey
- ShipDateKey

6. Change the **Name** property for the **Order Date Key** attribute to **Order Date**. Then, click the browse button for the **Name Column** property, and in the **Name Column** dialog box, select **Date** as the source table and select **SimpleDate** as the source column. Click **OK**.

7. Change the **Name** property for the **Due Date Key** attribute to **Due Date**, and then, by using the same method as the **Order Date Key** attribute, change the **Name Column** property for this attribute to **Date.SimpleDate (WChar)**.

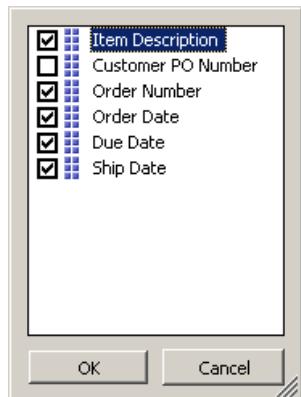

8. Change the **Name** property for the **Ship Date Key** attribute to **Ship Date**, and then change the **Name Column** property for this attribute to **Date.SimpleDate (WChar)**.

9. Switch to the **Actions** tab of Cube Designer for the Analysis Services Tutorial cube.

10. In the **Drillthrough Columns** box, select the check boxes to add the following columns to the **Return Columns** list, and then click **OK**:

- Order Date
- Due Date
- Ship Date

The following image shows these columns selected.

Reviewing the Modified Drillthrough Action

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to the **Browser** tab in Cube Designer for the Analysis Services Tutorial cube, and then click the **Reconnect** button.
3. Start Excel.
4. Recreate the PivotTable using **Internet Sales-Sales Amount** in the Values area and **Customer Geography** in the Report Filter.

Add a filter that selects from **All Customers, Australia, Queensland, Brisbane, 4000, Adam Powell**.

5. Click the **Internet Sales-Sales Amount** data cell, point to **Additional Actions**, and then click **Drillthrough to Order Details**.

The details of these orders shipped to Adam Powell are displayed in a temporary worksheet. This includes item description, order number, order date, due date, and ship date information, as shown in the following image.

| [Item Description] | [Order Number] | [Order Date] | [Due Date] | [Ship Date] |
|--------------------------------|----------------|--------------|------------|-------------|
| Road-250 Black, 48 | SO49206 | 20070204 | 20070216 | 20070211 |
| Road-350-W Yellow, 48 | SO61522 | 20080105 | 20080117 | 20080112 |
| Short-Sleeve Clasic Jersey, XL | SO61522 | 20080105 | 20080117 | 20080112 |

Lesson 9-1 - Defining and Browsing Perspectives

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

A perspective can simplify the view of a cube for specific purposes. By default, users can see all of the elements in a cube to which they have permissions. What users are viewing when they view an entire Analysis Services cube is the default perspective for the cube. A view of the whole cube can be very complex for users to navigate, especially for users who only need to interact with a small part of the cube to satisfy their business intelligence and reporting requirements.

To reduce the apparent complexity of a cube, you can create viewable subsets of the cube, called *perspectives*, which show users only a part of the measure groups, measures, dimensions, attributes, hierarchies, Key Performance Indicators (KPIs), actions, and calculated members in the cube. This can be particularly useful for working with client applications that were written for a previous release of Analysis Services. These clients have no concept of display folders or perspectives, for example, but a perspective appears to older clients as if it were a cube. For more information, see [Perspectives](#), and [Perspectives in Multidimensional Models](#).

NOTE

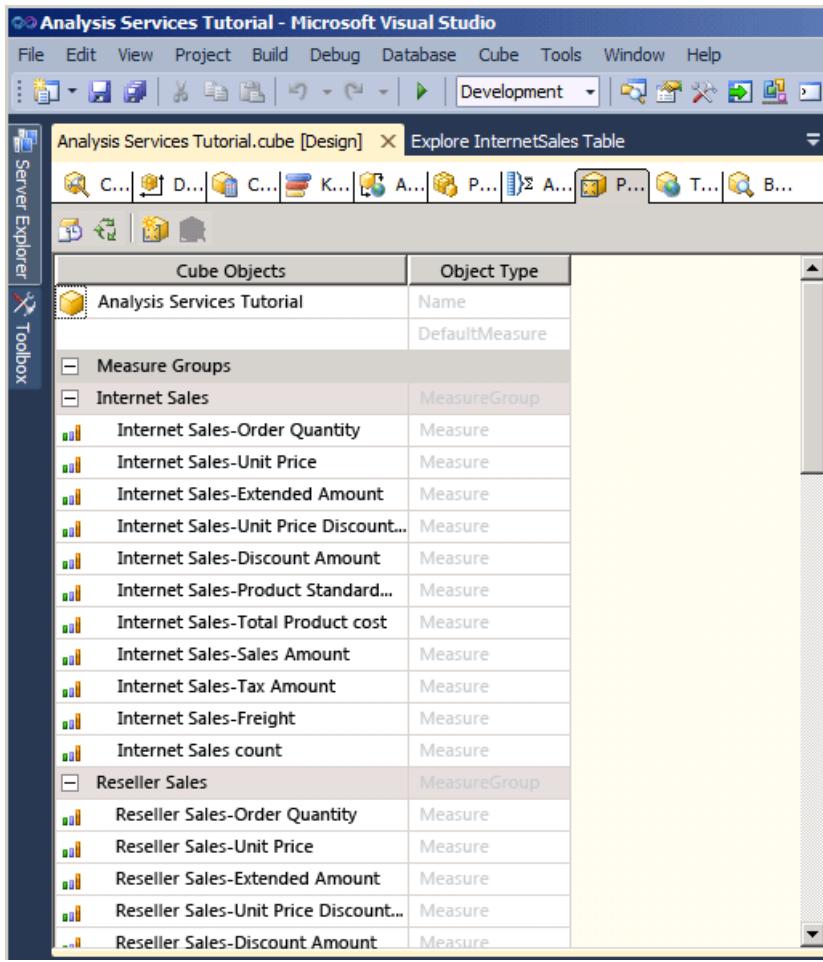

A perspective is not a security mechanism, but instead is a tool for providing a better user experience. All security for a perspective is inherited from the underlying cube.

In the tasks in this topic, you will define several different perspectives and then browse the cube through each of these new perspectives.

Defining an Internet Sales Perspective

1. Open Cube Designer for the Analysis Services Tutorial cube, and then click the **Perspectives** tab.

All the objects and their object types appear in the **Perspectives** pane, as shown in the following image.

2. On the toolbar of the **Perspectives** tab, click the **New Perspective** button.

A new perspective appears in the **Perspective Name** column with a default name of **Perspective**, as shown in the following image. Notice that the check box for every object is selected; until you clear the check box for an object, this perspective is identical to the default perspective of this cube.

| Cube Object | Object Type | Perspective Name |
|---------------------------------------|----------------|-------------------------------------|
| Analysis Services Tutorial | Name | Perspective |
| | DefaultMeasure | |
| Measure Groups | | |
| Internet Sales | MeasureGroup | <input checked="" type="checkbox"/> |
| Internet Sales-Order Quantity | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Unit Price | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Extended Amount | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Unit Price Discount... | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Discount Amount | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Product Standard... | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Total Product Cost | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Sales Amount | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Tax Amount | Measure | <input checked="" type="checkbox"/> |
| Internet Sales-Freight | Measure | <input checked="" type="checkbox"/> |
| Internet Sales Count | Measure | <input checked="" type="checkbox"/> |
| Reseller Sales | | |
| Reseller Sales | MeasureGroup | <input checked="" type="checkbox"/> |
| Reseller Sales-Order Quantity | Measure | <input checked="" type="checkbox"/> |
| Reseller Sales-Unit Price | Measure | <input checked="" type="checkbox"/> |
| Reseller Sales-Extended Amount | Measure | <input checked="" type="checkbox"/> |
| Reseller Sales-Unit Price Discount... | Measure | <input checked="" type="checkbox"/> |
| Reseller Sales-Discount Amount | Measure | <input checked="" type="checkbox"/> |

3. Change the perspective name to **Internet Sales**.
4. On the next row, set the DefaultMeasure to **Internet Sales-Sales Amount**.

When users browse the cube by using this perspective, this will be the measure that the users see unless they specify some other measure.

NOTE

You can also set the default measure for the whole Analysis Services Tutorial cube in the Properties window on the **Cube Structure** tab for the cube.

5. Clear the check box for the following objects:

- **Reseller Sales** measure group
- **Sales Quotas** measure group
- **Sales Quotas 1** measure group
- **Reseller** cube dimension
- **Reseller Geography** cube dimension
- **Sales Territory** cube dimension
- **Employee** cube dimension
- **Promotion** cube dimension
- **Reseller Revenue** KPI
- **Large Resellers** named set

- **Total Sales Amount** calculated member
- **Total Product Cost** calculated member
- **Reseller GPM** calculated member
- **Total GPM** calculated member
- **Reseller Sales Ratio to All Products** calculated member
- **Total Sales Ratio to All Products** calculated member

These objects do not relate to Internet sales.

NOTE

Within each dimension, you can also individually select the user-defined hierarchies and attributes that you want to appear in a perspective.

Defining a Reseller Sales Perspective

1. On the toolbar of the **Perspectives** tab, click the **New Perspective** button.
2. Change the name of the new perspective to **Reseller Sales**.
3. Set **Reseller Sales-Sales Amount** as the default measure.

When users browse the cube by using this perspective, this measure will be the measure that the users will see unless they specify some other measure.

4. Clear the check box for the following objects:

- **Internet Sales** measure group
- **Internet Sales Reason** measure group
- **Customer** cube dimension
- **Internet Sales Order Details** cube dimension
- **Sales Reason** cube dimension
- **Internet Sales Details Drillthrough Action** drillthrough action
- **Total Sales Amount** calculated member
- **Total Product Cost** calculated member
- **Internet GPM** calculated member
- **Total GPM** calculated member
- **Internet Sales Ratio to All Products** calculated member
- **Total Sales Ratio to All Products** calculated member

These objects do not relate to resellers sales.

Defining a Sales Summary Perspective

1. On the toolbar of the **Perspectives** tab, click the **New Perspective** button.

2. Change the name of the new perspective to **Sales Summary**.

NOTE

You cannot specify a calculated measure as the default measure.

3. Clear the check box for the following objects:

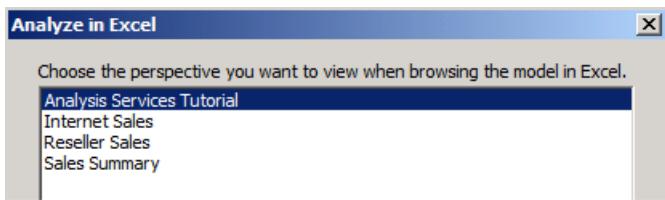

- **Internet Sales** measure group
- **Reseller Sales** measure group
- **Internet Sales Reason** measure group
- **Sales Quotas** measure group
- **Sales Quotas1** measure group
- **Internet Sales Order Details** cube dimension
- **Sales Reason** cube dimension
- **Internet Sales Details Drillthrough Action** drillthrough action

4. Select the check box for the following objects:

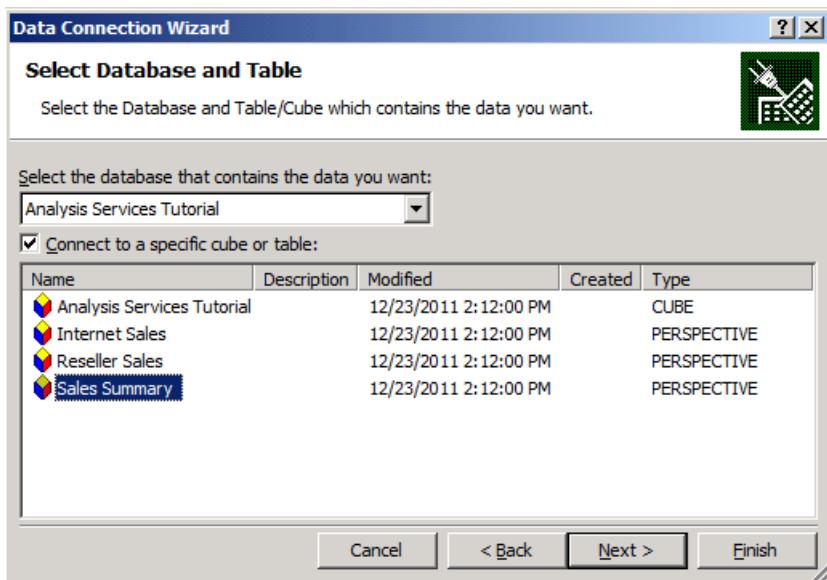

- **Internet Sales Count** measure
- **Reseller Sales Count** measure

Browsing the Cube Through Each Perspective

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to the **Browser** tab, and then click the **Reconnect** button.
3. Start Excel.
4. Analyze in Excel prompts you to choose which perspective to use when browsing the model in Excel, as shown in the following image.

5. Alternatively, you can start Excel from the Windows Start menu, define a connection to the Analysis Services Tutorial database on localhost, and choose a perspective in the Data Connection wizard, as shown in the following image.

6. Select **Internet Sales** in the **Perspective** list and then review the measures and dimensions in the metadata pane.

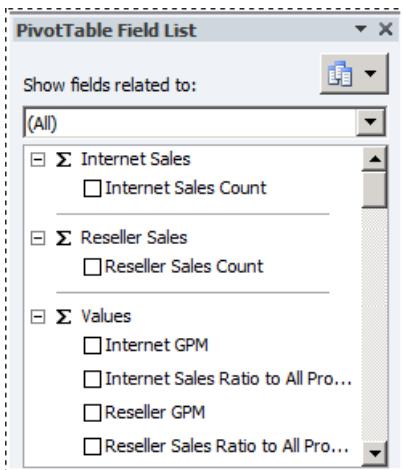

Notice that only those objects that are specified for the Internet Sales perspective appear.

7. In the metadata pane, expand **Measures**.

Notice that only the **Internet Sales** measure group appears, together with the **Internet GPM** and **Internet Sales Ratio to All Products** calculated members.

8. In the model, select Excel again. Select **Sales Summary**.

Notice that in each of these measure groups, only a single measure appears, as shown in the following image.

Next Task in Lesson

[Defining and Browsing Translations](#)

[Perspectives](#)

[Perspectives in Multidimensional Models](#)

Lesson 9-2 - Defining and Browsing Translations

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A translation is a representation of the names of Analysis Services objects in a specific language. Objects include measure groups, measures, dimensions, attributes, hierarchies, KPIs, actions, and calculated members. Translations provide server support for client applications that can support multiple languages. By using such a client, the client passes the locale identifier (LCID) to the instance of Analysis Services, which uses the LCID to determine which set of translations to use when it provides metadata for Analysis Services objects. If an Analysis Services object does not contain a translation for that language, or does not contain a translation for a specified object, the default language is used in returning the object metadata back to the client. For example, if a business user in France accesses a cube from a workstation that has a French locale setting, the business user will see the member captions and member property values in French if a French translation exists. However, if a business user in Germany accesses the same cube from a workstation that has a German locale setting, the business user will see the captions names and member property values in German. For more information, see [Dimension Translations](#), [Cube Translations](#), [Translation support in Analysis Services](#).

In the tasks in this topic, you define metadata translations for a limited set of dimension objects in the Date dimension and cube objects in the Analysis Services Tutorial cube. You will then browse these dimension and cube objects to examine the metadata translations.

Specifying Translations for the Date Dimension Metadata

1. Open Dimension Designer for the **Date** dimension, and then click the **Translations** tab.

The metadata in the default language for each dimension object appears. The default language in the Analysis Services Tutorial cube is English.

2. On the toolbar of the **Translations** tab, click the **New Translation** button.

A list of languages appears in the **Select Language** dialog box.

3. Click **Spanish (Spain)**, and then click **OK**.

A new column appears in which you will define the Spanish translations for the metadata objects you want to translate. In this tutorial, we will only translate a few objects just to illustrate the process.

4. On the toolbar of the **Translations** tab, click the **New Translation** button, click **French (France)** in the **Select Language** dialog box, and then click **OK**.

Another language column appears in which you will define French translations.

5. In the row for the **Caption** object for the **Date** dimension, type **Fecha** in the **Spanish (Spain)** translation column and **Temps** in the **French (France)** translation column.

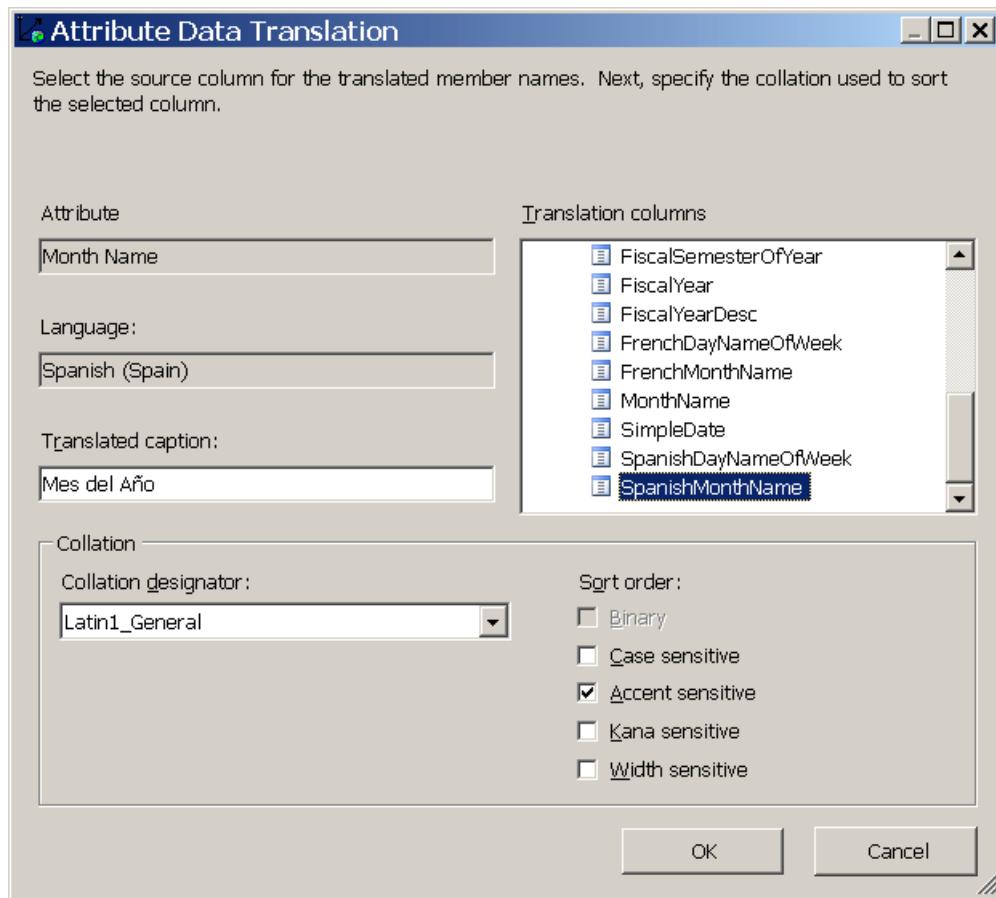

6. In the row for the **Caption** object for the **Month Name** attribute, type **Mes del Año** in the **Spanish (Spain)** translation column and **Mois d'Année** in the **French (France)** translation column.

Notice that when you enter these translations, an ellipsis (...) appears. Clicking this ellipsis will enable you to specify a column in the underlying table that provides translations for each member of the attribute hierarchy.

7. Click the ellipsis (...) for the **Spanish (Spain)** translation for the **Month Name** attribute.

The **Attribute Data Translation** dialog box appears.

8. In the **Translation columns** list, select **SpanishMonthName**, as shown in the following image.

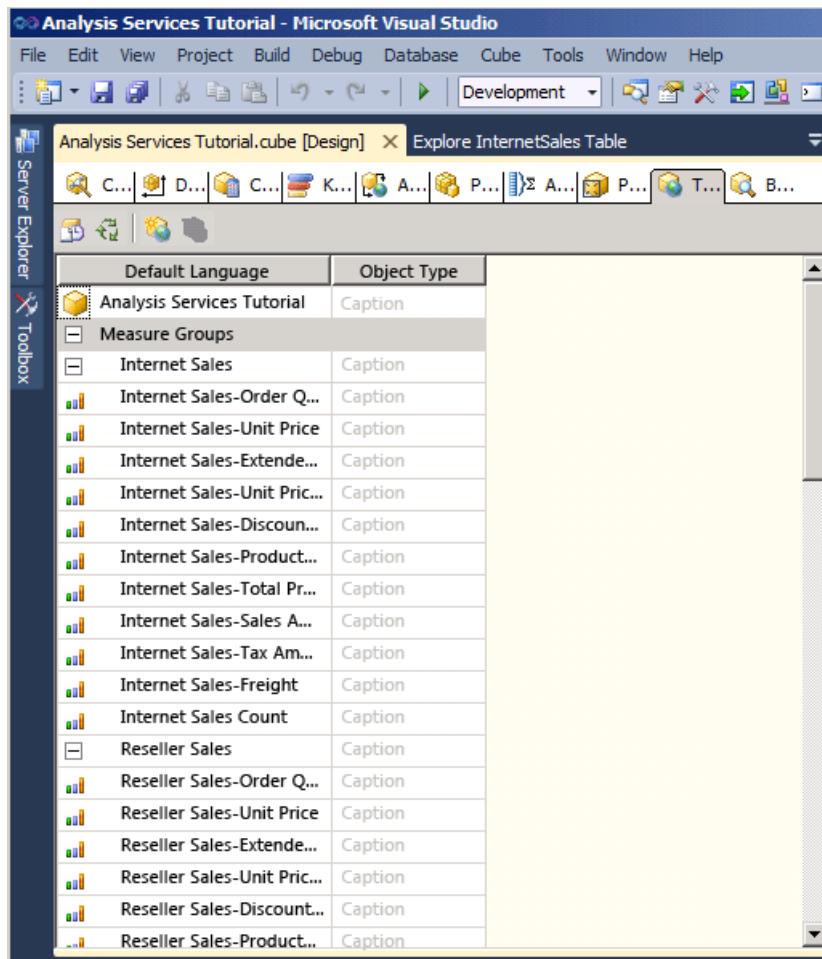

9. Click **OK**, and then click the ellipsis (...) for the **French (France)** translation for the **Month Name** attribute.
10. In the **Translation columns** list, select **FrenchMonthName**, and then click **OK**.

The steps in this procedure illustrate the process of defining metadata translations for dimension objects and members.

Specifying Translations for the Analysis Services Tutorial Cube Metadata

1. Switch to Cube Designer for the Analysis Services Tutorial cube, and then switch to the **Translations** tab.

The metadata in the default language for each cube object appears, as shown in the following image. The default language in the Analysis Services Tutorial cube is English.

2. On the toolbar of the **Translations** tab, click the **New Translation** button.

A list of languages appears in the **Select Language** dialog box.

3. Select **Spanish (Spain)**, and then click **OK**.

A new column appears in which you will define the Spanish translations for the metadata objects you want to translate. In this tutorial, we will only translate a few objects just to illustrate the process.

4. On the toolbar of the **Translations** tab, click the **New Translation** button, select **French (France)** in the **Select Language** dialog box, and then click **OK**.

Another language column appears in which you will define French translations.

5. In the row for the **Caption** object for the **Date** dimension, type **Fecha** in the **Spanish (Spain)** translation column and **Temps** in the **French (France)** translation column.
6. In the row for the **Caption** object for the **Internet Sales** measure group, type **Ventas del Internet** in the **Spanish (Spain)** translation column and **Ventes D'Internet** in the **French (France)** translation column.
7. In the row for the **Caption** object for the Internet Sales-Sales Amount measure, type **Cantidad de las Ventas del Internet** in the **Spanish (Spain)** translation column and **Quantité de Ventes d'Internet** in the **French (France)** translation column.

The steps in this procedure illustrate the process of defining metadata translations for cube objects.

Browsing the Cube By Using Translations

1. On the **Build** menu, click **Deploy Analysis Services Tutorial**.
2. When deployment has successfully completed, switch to the **Browser** tab, and then click **Reconnect**.

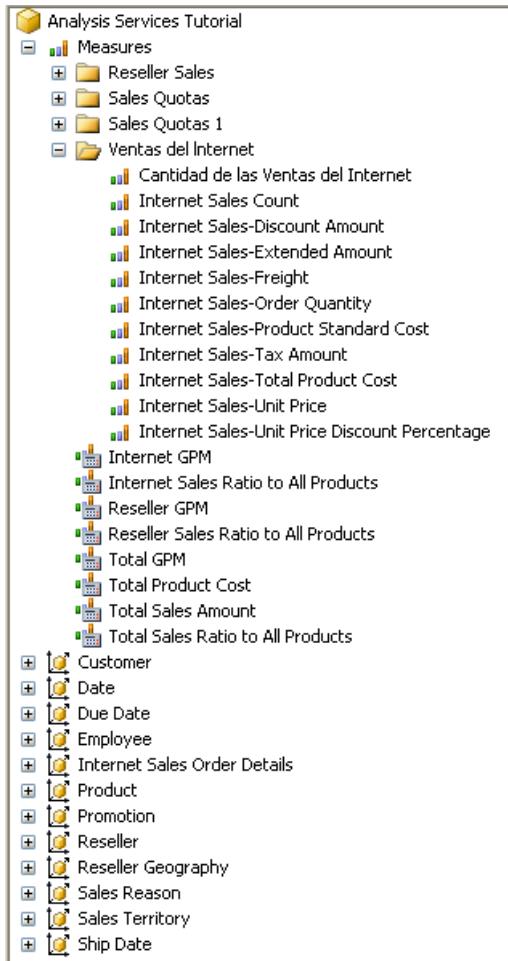

3. Remove all hierarchies and measures from the **Data** pane and select Analysis Services Tutorial in the **Perspectives** list.

4. In the metadata pane, expand **Measures** and then expand **Internet Sales**.

Notice that the **Internet Sales-Sales Amount** measure appears in English in this measure group.

5. On the toolbar, select **Spanish (Spain)** in the **Language** list.

Notice that the items in the metadata pane are repopulated. After the items in the metadata pane are repopulated, notice that the Internet Sales-Sales Amount measure no longer appears in the Internet Sales display folder. Instead, it appears in Spanish in a new display folder named **Ventas del Internet**, as shown in the following image.

6. In the metadata pane, right-click **Cantidad de las Ventas del Internet** and then select **Add to Query**.

7. In the metadata pane, expand **Fecha**, expand **Fecha.Calendar Date**, right-click **Fecha.Calendar Date**, and then select **Add to Filter**.

8. In the **Filter** pane, select **CY 2007** as the filter expression.

9. In the metadata pane, right-click **Mes del Año** and select **Add to Query**.

Notice that the month names appear in Spanish, as shown in the following image.

| Dimension | Hierarchy | Operator | Filter Expression |
|--------------------|---------------------|----------|-------------------|
| Fecha | Fecha.Calendar Date | Equal | { CY 2007 } |
| <Select dimension> | | | |
|
 | | | |
| Mes del Año | Cantidad de la... | | |
| Enero | 438865.1718 | | |
| Febrero | 489090.3356 | | |
| Marzo | 485574.7923 | | |
| Abril | 506399.2654 | | |
| Mayo | 562772.5645 | | |
| Junio | 554799.2281 | | |
| Julio | 886668.84 | | |
| Agosto | 847413.5100... | | |
| Septiembre | 1010258.13 | | |
| Octubre | 1080449.58 | | |
| Noviembre | 1196981.11 | | |
| Diciembre | 1731787.77 | | |

10. On the toolbar, select **French (France)** in the **Language** list.

Notice that the month names now appear in French and that the measure name now also appears in French.

Lesson 10: Defining Administrative Roles

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In this lesson, you learn to define security roles for administrative tasks.

NOTE

Completed projects for all of the lessons in this tutorial are available online. You can jump ahead to any lesson by using the completed project from the previous lesson as a starting point. [Click here](#) to download the sample projects that go with this tutorial.

This lesson contains the following task:

[Granting Process Database Permissions](#)

In this task, you define a security role that has permissions to process the Analysis Services database, and then you test this security role.

See Also

[Analysis Services Tutorial Scenario](#)

[Multidimensional Modeling \(Adventure Works Tutorial\)](#)

Lesson 10 - Granting Process Database Permissions

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

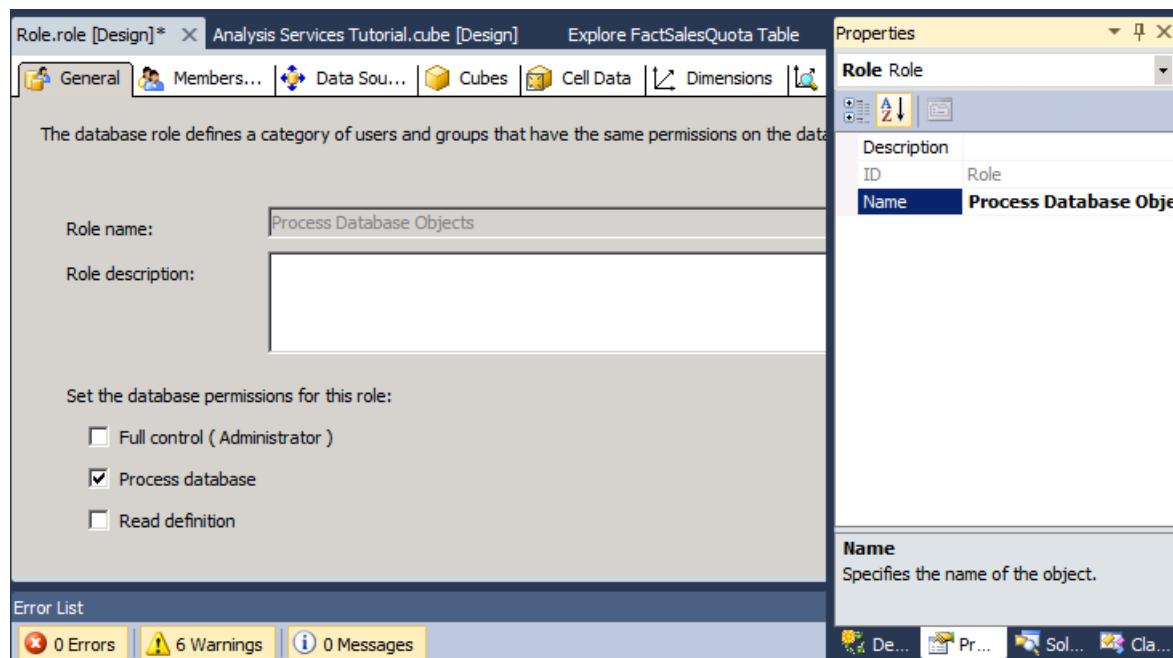

After you install an instance of Analysis Services, all members of the Analysis Services server administrator role in that instance have server-wide permissions to perform any task within the instance of Analysis Services. By default, no other users have any permission to administer or view any objects in the instance of Analysis Services.

A member of the server administrator role can grant users administrative access on a server-wide basis by making them members of the role. A member of the server administrator role can also grant users access on a more limited basis by granting them limited or complete administrative or access permissions at the database level. Limited administrative permissions include process or read definition permissions at the database, cube, or dimension level.

In the tasks in this topic, you will define a Process Database Objects security role that grants members of the role permission to process all database objects, but no permission to view data within the database.

Defining a Process Database Objects Security Role

1. In Solution Explorer, right-click **Roles** and then click **New Role** to open the Role Designer.
2. Click the **Process database** check box.
3. In the Properties window, change the **Name** property for this new role to **Process Database Objects Role**.

4. Switch to the **Membership** tab of Role Designer and click **Add**.
5. Enter the accounts of the Windows domain users or groups who will be members of this role. Click **Check Names** to verify the account information, and then click **OK**.
6. Switch to the **Cubes** tab of Role Designer.

Notice that members of this role have permissions to process this database, but have no permission to

access the data in the Analysis Services Tutorial cube and have no local cube/drillthrough access, as shown in the following image.

The screenshot shows the Microsoft SQL Server Management Studio (SSMS) interface for the 'Role.role [Design]' window. The title bar says 'Analysis Services Tutorial.cube [Design]'. Below the title bar is a toolbar with icons for Generate, Members, Data, Cube, Cells, Dimensions, and Minimums. The main area is titled 'Cube:' and contains a table with one row. The table has four columns: 'Cube Name', 'Access', 'Local Cube/Drillthrou...', and 'Process'. The 'Cube Name' column contains 'Analysis Services Tutorial'. The 'Access' column contains 'None'. The 'Local Cube/Drillthrou...' column contains 'None'. The 'Process' column contains a checked checkbox. The entire table is highlighted with a light gray selection.

7. Switch to the **Dimensions** tab of Role Designer.

Notice that members of this role have permissions to process all dimension objects in this database, and, by default, have read permissions to access each dimension object in the Analysis Services Tutorial database.

8. On the **Build** menu, click **Deploy Analysis Services Tutorial**.

You have now successfully defined and deployed the Process Database Objects security role. After a cube is deployed to the production environment, the administrators of the deployed cube can add users to this role as required to delegate processing responsibilities to specific users.

NOTE

A completed project for Lesson 10 is available by downloading and installing the samples. For more information, see [Install Sample Data and Projects for the Analysis Services Multidimensional Modeling Tutorial](#).

[Roles and Permissions \(Analysis Services\)](#)

Data Mining Tutorials (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Microsoft SQL Server Analysis Services makes it easy to create data mining solutions using wizards and integrated visualizations. Particularly if you are new to machine learning, the tools in Analysis Services are an easy way to design, train, and explore data mining models. The data in your models can be stored in a cube, relational database, or any other source supported by Analysis Services. After creating a model, you can put it into production by accessing the model to create predictions using prediction multiple clients, including Integration Services and ASP.NET.

NOTE

The tutorials described here have not been updated for SQL Server 2017. You can use the tutorials created for SQL Server 2014. Functionally, there are no changes in Data Mining features for SQL Server 2017. The steps should be identical.

Tutorials

[Basic Data Mining Tutorial \(SQL Server 2014\)](#) - This tutorial walks you through a targeted mailing scenario. It demonstrates how to use the data mining algorithms, mining model viewers, and data mining tools that are included in Analysis Services. You will build three data mining models to answer practical business questions while learning data mining concepts and tools.

[Intermediate Data Mining Tutorial \(SQL Server 2014\)](#) - This tutorial contains a collection of lessons that introduce more advanced data mining concepts and techniques such as, forecasting, market basket analysis, neural networks and logistic regression, and sequence clustering.

[DMX Tutorials \(SQL Server 2014\)](#) - The Data Mining Extensions (DMX) query language has syntax like that of SQL but can be used to create, query, and manage predictive models stored in Analysis Services. These tutorials demonstrate how to create a new mining structure and mining models by using the DMX language, and how to create DMX prediction queries for use in applications.

[Creating and Querying Data Mining Models with DMX: Tutorials \(Analysis Services - Data Mining\)](#)

Install SQL Server Analysis Services

10/22/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services ✗ Azure Analysis Services ✗ Power BI Premium

SQL Server Analysis Services is installed by using the [SQL Server Installation Wizard](#).

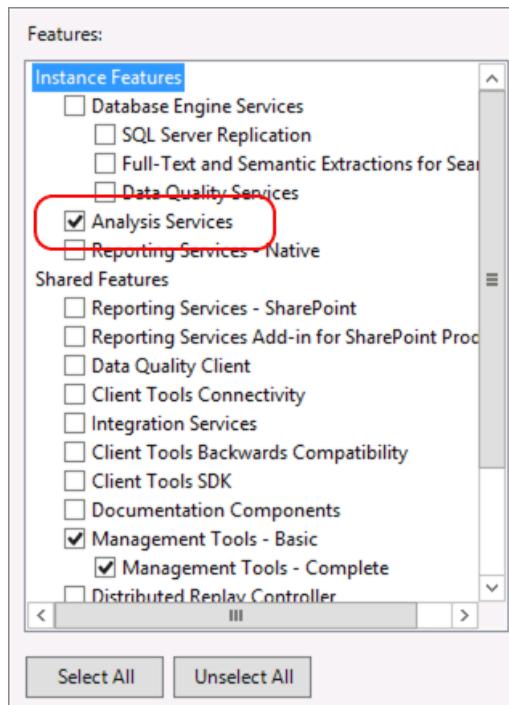

SQL Server Analysis Services is multi-instance, which means that you can install more than one copy on a single computer, or run new and old versions side-by-side. Any instance you install runs in one of three modes, as determined during setup: Multidimensional and Data Mining, Tabular, or SharePoint. If you want to use multiple modes, you'll need a separate instance for each one.

After you install the server in a particular mode, you can use it host solutions that conform to that mode. For example, a tabular mode server is required if you want tabular model data access over the network.

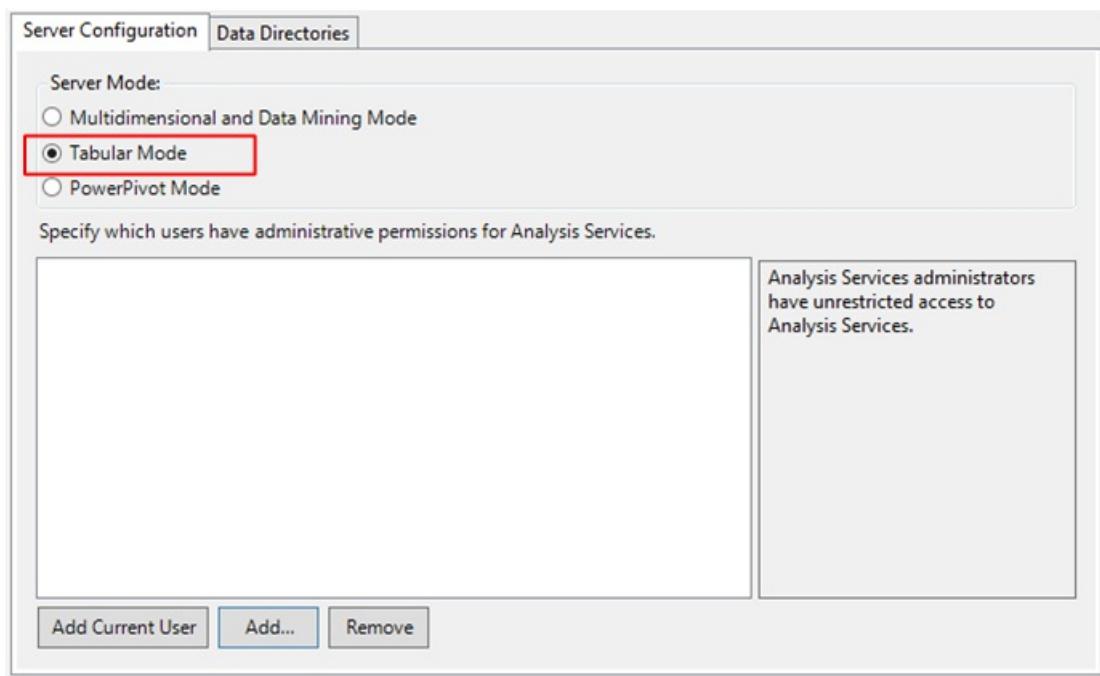

Install using the wizard

The following shows which pages in the SQL Server Installation wizard are used to install Analysis Services.

1. Select **Analysis Services** from the Feature Tree in Setup.

2. On the Analysis Services Configuration page, select a mode. Tabular mode is the default..

Tabular mode uses the VertiPaq in-memory analytics engine (VertiPaq), which is the default storage for tabular models. After you deploy tabular models to the server, you can selectively configure tabular solutions to use DirectQuery disk storage as an alternative to memory-bound storage.

Multidimensional and Data Mining mode use MOLAP as the default storage for models deployed to Analysis Services. After deploying to the server, you can configure a solution to use ROLAP if you want to run queries directly against the relational database rather than storing query data in an Analysis Services multidimensional database .

Memory management and IO settings can be adjusted to get better performance when using non-default storage modes. See [Server properties in Analysis Services](#) for more information.

Command Line Setup

SQL Server Setup includes a parameter (**ASSERVERMODE**) that specifies the server mode. The following example illustrates a command line setup that installs Analysis Services in Tabular server mode.

```
Setup.exe /q /IAcceptSQLServerLicenseTerms /ACTION=install /FEATURES=AS /ASSERVERMODE=TABULAR  
/INSTANCENAME=ASTabular /INDICATEPROGRESS /ASSVCACCOUNT=<DomainName\UserName> /ASSVCPASSWORD=<StrongPassword>  
/ASSYSADMINACCOUNTS=<DomainName\UserName>
```

INSTANCENAME must be less than 17 characters.

All placeholder account values must be replaced with valid accounts and password.

ASSERVERMODE is case-sensitive. All values must be expressed in upper case. The following table describes the valid values for **ASSERVERMODE**.

| VALUE | DESCRIPTION |
|------------------|---|
| TABULAR | This is the default value. If you do not set ASSERVERMODE , the server is installed in Tabular mode. |
| MULTIDIMENSIONAL | This value is optional. |

| VALUE | DESCRIPTION |
|------------|--|
| POWERPIVOT | This value is optional. In practice, if you set the ROLE parameter, the server mode is automatically set to 1, making ASSERVERMODE optional for a Power Pivot for SharePoint installation. For more information, see Install Power Pivot from the Command Prompt . |

Get tools and designers

SQL Server Setup no longer installs the model designers or management tools used for solution design or server administration. In this release, tools have a separate installation, which you can get from the following links:

- [Download Visual Studio 2019](#)
- [Download Analysis Services projects extension](#)

You'll need both Visual Studio and SSMS to create, deploy, and work with Analysis Services instances and databases. Tools can be installed anywhere, but be sure to configure ports on the server before attempting a connection. See [Configure the Windows Firewall to Allow Analysis Services Access](#) for details.

See also

[Determine the Server Mode of an Analysis Services Instance](#)

Install Analysis Services in Power Pivot Mode

8/8/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

The procedures in this topic guide you through a single server installation of a Analysis Services server in Power Pivot mode for a SharePoint deployment. The steps include running the SQL Server installation wizard as well as configuration tasks that use SharePoint Central Administration.

Background

Power Pivot for SharePoint is a collection of middle-tier and backend services that provide Power Pivot data access in a SharePoint 2016, or SharePoint 2013, farm.

- **Backend services:** If you use Power Pivot for Excel to create workbooks that contain analytical data, you must have Power Pivot for SharePoint to access that data in a server environment. You can run SQL Server Setup on a computer that has SharePoint Server installed, or on a different computer that has no SharePoint software. Analysis Services does not have any dependencies on SharePoint.

Note: This topic describes the installation of the Analysis Services server and the backend services.

- **Middle-tier:** Enhancements to the Power Pivot experiences in SharePoint including Power Pivot Gallery, Schedule data refresh, Management dashboard, and data providers. For more information on installing and configuring the middle-tier, see the following:
 - [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2016\)](#)
 - [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)
 - [Configure Power Pivot and Deploy Solutions \(SharePoint 2016\)](#)
 - [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#)

Prerequisites

1. You must be a local administrator to run SQL Server Setup.
2. SharePoint Server enterprise edition is required for Power Pivot for SharePoint. You can also use the evaluation enterprise edition.
3. The computer must be joined to a domain in the same Active Directory forest as the Office Online Server (SharePoint 2016) or Excel Services (SharePoint 2013).
4. The Power Pivot instance name must be available. You cannot have an existing Power Pivot-named instance on the computer on which you are installing Analysis Services in Power Pivot mode.

Note: The instance name must be POWERPIVOT.

5. Review [Hardware and Software Requirements for Analysis Services Server in SharePoint Mode](#).
6. Review the release notes at [SQL Server 2016 Release Notes](#).

SQL Server Edition Requirements

Business intelligence features are not all available in all editions of SQL Server 2017. For details, see [Analysis Services Features Supported by the Editions of SQL Server 2016](#) and [Editions and Components of SQL Server](#)

2016.

Step 1: Install Power Pivot for SharePoint

In this step, you run SQL Server Setup to install an Analysis Services server in Power Pivot mode. In a subsequent step, you configure Excel Services to use this server for workbook data models.

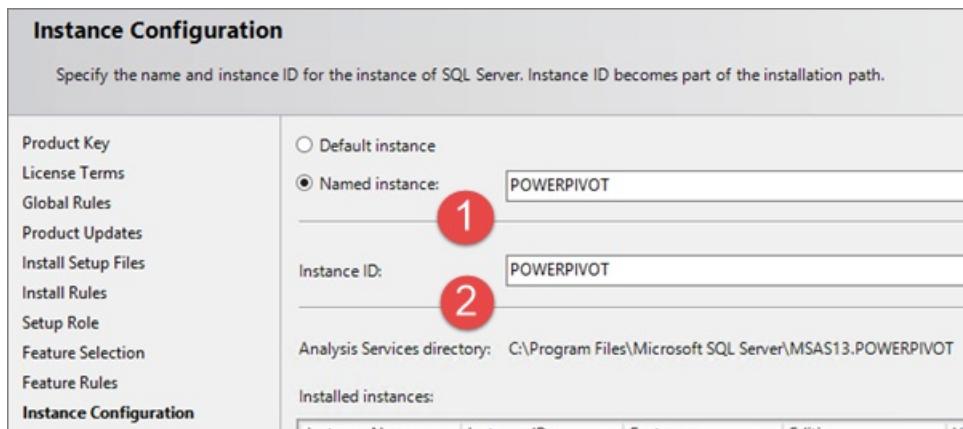

1. Run the SQL Server Installation Wizard (Setup.exe).
2. select **Installation** in the left navigation.
3. select **New SQL Server stand-alone installation or add features to an existing installation**.
4. If you see the **Product Key** page, specify the evaluation edition or enter a product key for a licensed copy of the enterprise edition. select **Next**. For more information on editions, see [Editions and Components of SQL Server 2016](#).
5. Review and accept the Microsoft Software License Terms of agreement, and then select **Next**.
6. If you see the **Global Rules** page, review any rules information the setup wizard displays.
7. On the **Microsoft Update** page, it is recommended you use Microsoft Update to check for updates, then select **Next**.
8. The **Install Setup Files** page runs for several minutes. Review any rule warnings or failed rules, and then select **Next**.
9. If you see another **Setup Support Rules**, review any warnings and select **Next**.

Note: Because Windows Firewall is enabled, you see a warning to open ports to enable remote access.

10. On the **Setup Role** page, select **SQL Server Feature Installation**.

Select **Next**.

11. On the Feature Selection page, select **Analysis Services**. This option allows you to install any of the three Analysis Services modes. You will select the mode in a later step. Select **Next**.
12. On the **Instance Configuration** page, select **Named Instance** and type **POWERPIVOT** for the instance name Click **Next**.

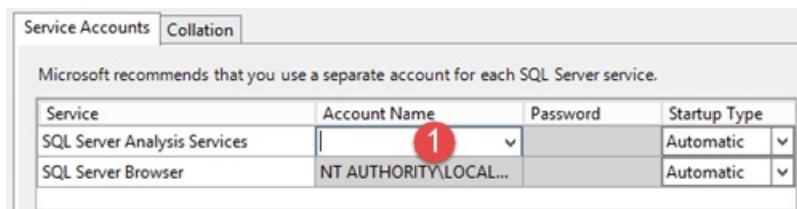

13. On the **Server Configuration** page, configure all of the services for Automatic **Startup Type**. Specify the desired domain account and password for **SQL Server Analysis Services**, (1) in the following diagram.
 - For Analysis Services, you can use a **domain user** account or **NetworkService** account. Do not use LocalSystem or LocalService accounts.
 - If you added the SQL Server Database Engine and SQL Server Agent, you can configure the

services to run under domain user accounts or under the default virtual account.

- Never provision service accounts with your own domain user account. Doing so grants the server the same permissions that you have to the resources in your network. If a malicious user compromises the server, that user is logged in under your domain credentials. The user has the permissions to download or use the same data and applications that you do.

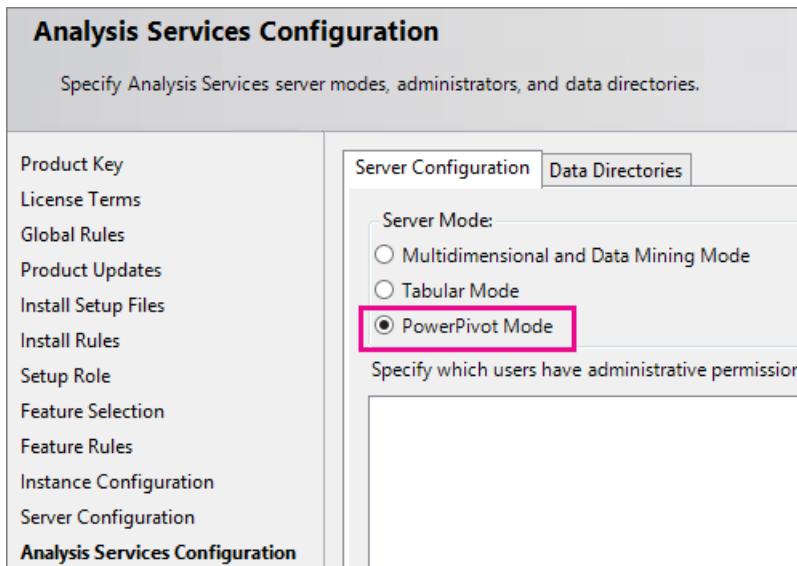

Select **Next**.

- If you are installing the Database Engine, the **Database Engine Configuration** page appears. In Database Engine Configuration, select **Add Current User** to grant your user account administrator permissions on the Database Engine instance.

Select **Next**.

- On the **Analysis Services Configuration** page, select **PowerPivot Mode** under **Server Mode**

- On the **Analysis Services Configuration** page, select **Add Current User** to grant your user account administrative permissions. You will need administrative permission to configure the server after Setup is finished.

- In the same page, add the Windows user account of any person who also requires administrative permissions. For example, any user who wants to connect to the Analysis Services service instance in SQL Server Management Studio to troubleshoot database connection problems must have system administrator permissions. Add the user account of any person who might need to troubleshoot or administer the server now.

- NOTE**

All service applications that require access to the Analysis Services server instance need to have Analysis Services Administrative permissions. For example, add the service accounts for Excel Services, Power View, and Performance Point Services. Also, add the SharePoint farm account, which is used as the identity of the web application that hosts Central Administration.

Select **Next**.

17. On the **Error Reporting** page, select **Next**.
18. On the **Ready to Install** page, select **Install**.
19. If you see the dialog **Computer Restart Required**, select **OK**.
20. When the installation is complete, select **Close**.
21. Restart the computer.
22. If you have a firewall in your environment, review the SQL Server Books Online topic, [Configure the Windows Firewall to Allow Analysis Services Access](#).

Verify the SQL Server Installation

Verify that the Analysis Services Service is running.

1. In Microsoft Windows click **Start**, select **All Programs**, and select the **Microsoft SQL Server** group.
2. Select **SQL Server Management Studio**.
3. Connect to the Analysis Services instance, for example **[your server name]\POWERPIVOT**. If you can connect to the instance, you have verified the Service is running.

Step 2: Configure Basic Analysis Services SharePoint Integration

The following steps describe configuration changes needed so you can interact with Excel advanced data models inside a SharePoint document library. Complete these steps after you install SharePoint and SQL Server Analysis Services.

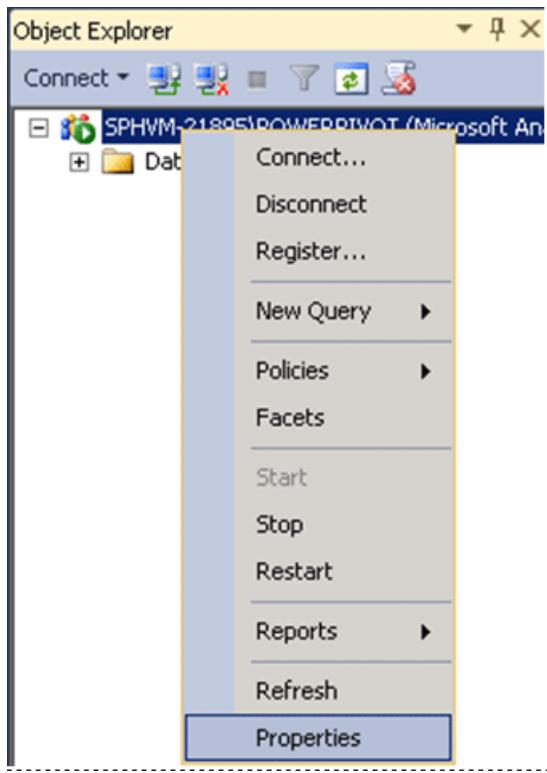

SharePoint 2016

Excel Services was removed from SharePoint 2016, and instead uses Office Online Server for hosting Excel.

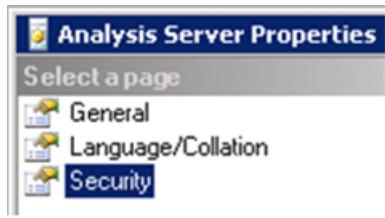

Grant Office Online Server machine account Administration Rights on Analysis Services

You do not need to complete this section if during the Analysis Services installation; you added the Office Online Server machine account as an Analysis Services administrator.

1. On the Analysis Services server, start SQL Server Management Studio and connect to the Analysis Services instance, for example **[MyServer]\POWERPIVOT**.
2. In Object Explorer, right-click the instance name and select **Properties**.

3. In the left pane, select **Security**. Add the machine account that the Office Online Server is installed on.

Register Analysis Services server with Office Online Server

You will want to perform these steps on the Office Online Server.

- Open a PowerShell command window as an administrator.
- Load the `OfficeWebApps` PowerShell module.

```
Import-Module OfficeWebApps
```

- Add the Analysis Services server, for example `[MyServer]\POWERPIVOT`.

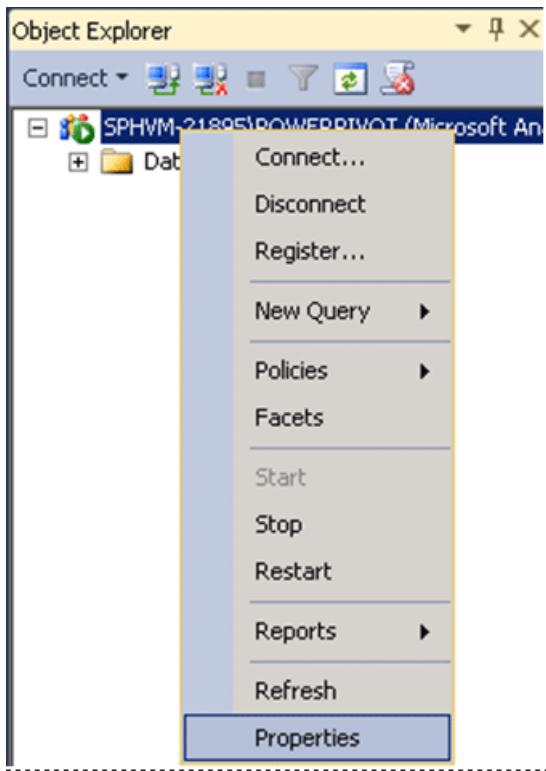

```
New-OfficeWebAppsExcelBIServer -ServerId [MyServer]\POWERPIVOT
```

SharePoint 2013

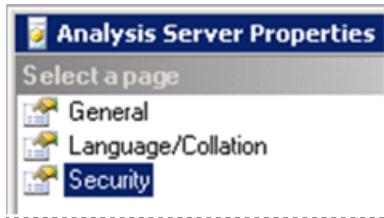

Grant Excel Services Server Administration Rights on Analysis Services

You do not need to complete this section if during the Analysis Services installation; you added the Excel Services Application service account as an Analysis Services administrator.

1. On the Analysis Services server, start SQL Server Management Studio and connect to the Analysis Services instance, for example `[MyServer]\POWERPIVOT`.
2. In Object Explorer, right-click the instance name and select **Properties**.

- In the left pane, select **Security**. Add the domain login you configured for the Excel Services Application in step 1.

Configure Excel Services for Analysis Services integration

- In SharePoint Central Administration, in the Application Management group, click **Manage Service Applications**.
- Click the name of your service application, the default is **Excel Services Application**.
- On the **Manage Excel Services Application** page, click **Data Model Settings**.
- Click **Add Server**.
- In **Server Name**, type the Analysis Services server name and the Power Pivot instance name. For example `MyServer\POWERPIVOT`. The Power Pivot instance name is required.

Type a description.

- Click **Ok**.
- The changes will take effect in a few minutes or you can **Stop** and **Start** the service **Excel Calculation Services**. To

Another option is to open a command prompt with administrative privileges, and type `iisreset /noforce`.

You can verify the server is recognized by Excel Services by reviewing entries in the ULS log. You will see entries similar to the following:

| | | | | |
|--|------------|--------------------------------------|--------|--------------|
| Excel Services Application | Data Model | 27 | Medium | Check |
| Administrator Access ([ServerName]\POWERPIVOT): Pass. | | f127bd9b-bae3-e0e0-9b48-3f7b5ad1eae6 | | |
| Excel Services Application | Data Model | 27 | Medium | Check Server |
| Version ([ServerName]\POWERPIVOT): Pass (11.0.2809.24 >= 11.0.2800.0). | | f127bd9b-bae3-e0e0-9b48-3f7b5ad1eae6 | | |
| Excel Services Application | Data Model | 27 | Medium | Check |
| Deployment Mode ([ServerName]\POWERPIVOT): Pass. | | f127bd9b-bae3-e0e0-9b48-3f7b5ad1eae6 | | |

Step 3: Verify the Integration

The following steps walk you through creating and uploading a new workbook to verify the Analysis Services integration. You will need a SQL Server database to complete the steps.

1. **Note:** If you already have an advanced workbook with slicers or filters, you can upload it to your SharePoint document library and verify you are able to interact with the slicers and filters from the document library view.
2. Start a new workbook in Excel.
3. On the Data tab, select **From Other Sources** on the ribbon in the **Get External Data**.
4. Select **From SQL Server**.
5. In the **Data Connection Wizard**, enter the name of the SQL Server instance that has the database you want to use.
6. Under Log on credentials, verify that **Use Windows Authentication** is selected, and then select **Next**.
7. Select the database you want to use.
8. Verify that the **Connect to specific table** checkbox is selected.
9. Select the **Enable selection of multiple tables and add tables to the Excel Data Model** checkbox.
10. Select the tables you want to import.
11. Select the checkbox **Import relationships between selected tables**, and then select **Next**. Importing multiple tables from a relational database lets you work with tables that are already related. You save steps because you don't have to build the relationships manually.
12. In the **Save Data Connection File and Finish** page of the wizard, type a name for your connection and select **Finish**.
13. The **Import Data** dialog box will appear. Choose **PivotTable Report**, and then select **Ok**.
14. A PivotTable Field List appears in the workbook.
On the field list, select the **All** tab
15. Add fields to the Row, Columns, and Value areas in the field list.
16. Add a slicer or a filter to the PivotTable. **Do not skip this step**. A slicer or filter is the element that will help you verify your Analysis Services installation.
17. Save the workbook to a document library in your SharePoint farm. You can also save the workbook to a file share and then upload it to the SharePoint document library.
18. Select the name of your workbook to view it in Excel Online and click the slicer or change the filter that you previously added. If a data update occurs, you know that Analysis Services is installed and available to Excel. If you open the workbook in Excel you will be using a cached copy and not using the Analysis

Services server.

Configure the Windows Firewall to Allow Analysis Services Access

Use the information in the topic [Configure the Windows Firewall to Allow Analysis Services Access](#) to determine whether you need to unblock ports in a firewall to allow access to Analysis Services or Power Pivot for SharePoint. You can follow the steps provided in the topic to configure both port and firewall settings. In practice, you should perform these steps together to allow access to your Analysis Services server.

Upgrade Workbooks and Scheduled Data Refresh

The steps required to upgrade workbooks created in previous versions of Power Pivot depend on what version of Power Pivot created the workbook. For more information, see [Upgrade Workbooks and Scheduled Data Refresh \(SharePoint 2013\)](#).

Beyond the Single-Server Installation - Power Pivot for Microsoft SharePoint

Web front-end (WFE) or Middle-tier: To use an Analysis Services server in SharePoint mode in a larger SharePoint farm and to install additional Power Pivot features into the farm, run the installer package **spPowerPivot16.msi (SharePoint 2016), or spPowerPivot.msi (SharePoint 2013)**, on each of the SharePoint servers. The spPowerPivot16.msi, or spPowerPivot.msi, installs required data providers and the Power Pivot for SharePoint 2016, or 2013, Configuration tool.

For more information on installing and configuring the middle-tier, see the following:

- [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)
- [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)
- To download the .msi, see [Microsoft SQL Server 2016 Power Pivot for Microsoft SharePoint 2016](#)
- [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#)

Redundancy and server load: Installing a second, or more Analysis Services servers in Power Pivot mode will provide redundancy of the Analysis Services server functionality. Additional servers will also spread the load across servers. For more information, see the following:

- [Configure Analysis Services for processing data models in Excel Services \(SharePoint 2013\).](#)
- [Manage Excel Services data model settings \(SharePoint 2013\).](#)
- [!\[\]\(5f8b61aad6ad84adaa2afdb193e9f53c_img.jpg\) Submit feedback and contact information through SQL Server Feedback.](#)

[Migrate Power Pivot to SharePoint 2013](#)

[Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)

[Upgrade Workbooks and Scheduled Data Refresh \(SharePoint 2013\)](#)

Install or Uninstall the Power Pivot for SharePoint Add-in (SharePoint 2016)

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Power Pivot for SharePoint 2013 is a collection of application server components and back-end services that provide Power Pivot data access in a SharePoint Server 2016 farm. The Power Pivot for SharePoint add-in (**spPowerpivot16.msi**) is an installer package used to install the application server components.

Note: This topic describes installing the Power Pivot solution files and Power Pivot for SharePoint 2016 Configuration tool. After the installation, see the following topic for information on the configuration tool and additional features, [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#).

For information on how to download **spPowerpivot16.msi**, see [Microsoft® SQL Server® 2016 Power Pivot® for Microsoft SharePoint®](#).

Background

- **Application Server:** Power Pivot functionality in SharePoint 2016 includes using workbooks as a data source, scheduled data refresh, and the Power Pivot Management Dashboard.

Power Pivot for SharePoint 2016 is a Microsoft Windows Installer package (**spPowerpivot16.msi**) that deploys Analysis Services client libraries and copies Power Pivot for SharePoint 2013 installation files to the computer. The installer does not deploy or configure Power Pivot features in SharePoint. The following components install by default:

- Power Pivot for SharePoint 2016. This component includes PowerShell scripts (.ps1 files), SharePoint solution packages (.wsp), and the Power Pivot for SharePoint 2016 configuration tool to deploy Power Pivot in a SharePoint 2016 farm.
- Microsoft OLE DB Provider for Analysis Services (MSOLAP).
- ADOMD.NET data provider.
- SQL Server Analysis Management Objects.

- **Backend services:** If you use Power Pivot for Excel to create workbooks that contain analytical data, you must have Office Online Server configured with a BI server running Analysis Services in Power Pivot mode to access that data in a server environment. You can run SQL Server Setup on a computer that has SharePoint Server 2016 installed, or on a different computer that has no SharePoint software. Analysis Services does not have any dependencies on SharePoint.

For more information on installing, uninstalling, and configuring the backend services, see the following:

- [Install Analysis Services in Power Pivot Mode](#)
- [Uninstall Power Pivot for SharePoint](#)

Where to Install spPowerpivot16.msi?

A recommended best practice is to install **spPowerpivot16.msi** on all servers in the SharePoint farm for configuration consistency, including application servers and web-front end servers. The installer package includes

the Analysis Services data providers as well as the Power Pivot for SharePoint 2016 configuration tool. When you install **spPowerPivot16.msi** you can customize the installation by excluding individual components.

Data providers: Several SharePoint and SQL Server technologies use the Analysis Services data providers including PerformancePoint Services and Power View. Installing **spPowerPivot16.msi** on all SharePoint servers ensures the full set of Analysis Services data providers and Power Pivot connectivity is consistently available across the farm.

NOTE

You must install the Analysis Services data providers on a SharePoint 2016 server using **spPowerPivot16.msi**. Other installer packages available in the SQL Server 2017 Feature Pack are not supported because these packages do not include the SharePoint 2016 support files that the data providers require in this environment.

Configuration Tool: The Power Pivot for SharePoint 2016 configuration tool is required on only one of the SharePoint servers. However a recommended best practice in multi-server farms is to install the configuration tool on at least two servers so you have access to the configuration tool if one of the two servers is offline.

Requirements and Prerequisites

- Microsoft SharePoint Server 2016.
- **spPowerPivot16.msi** is 64-bit only, in accordance with the requirements of SharePoint products and technologies.
- A server in Power Pivot mode. Office Online Server will use the SQL Server Analysis Services instance as a Power Pivot server. Analysis Services can run on the local SharePoint server or a remote computer. It cannot be installed on the Office Online Server.
- **Permissions:** To install Power Pivot for SharePoint 2016, the current user is required to be an administrator on the computer and in the SharePoint Farm Administrators group.
- For more information on Power Pivot for SharePoint requirements and pre-requisites, go to [Hardware and Software Requirements for Analysis Services Server in SharePoint Mode](#).

To Install Power Pivot for SharePoint

The **spPowerpivot16.msi** installer package supports both a graphical user interface and a command-line mode. Both methods of installation require that you run the .msi with administrator privileges. After the installation, see the following topic for information on the configuration tool and additional features, [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#).

User interface installation

To install Power Pivot for SharePoint 2016 with the graphical user interface, complete the following steps:

1. Run **spPowerPivot16.msi**.
2. Select **Next** on the Welcome page.
3. Review and accept the license agreement, then select **Next**.
4. On the **Feature Selection** page, all of the features are selected by default.
5. Select **Next**.
6. Select **Install** to install to finish the installation.

Command Line Installation

For a command-line installation, open a command prompt with administrative permissions, and then run the **spPowerPivot16.msi**. For example:

```
Msiexec.exe /i spPowerPivot16.msi .
```

To create an installation log, use the standard MsiExec logging switches. The following example creates the log file "Install_Log.txt" using the "v" verbose logging switch.

```
Msiexec.exe /i spPowerPivot16.msi /L v c:\test\Install_Log.txt
```

Quiet Command Line Installation for scripting

You can use the **/q** or **/quiet** switches for a "quiet" installation that will not display any dialogs or warnings. The quiet installation is useful if you want to script the installation of the add-in.

IMPORTANT

If you use the **/q** switch for a silent command line installation, the end-user license agreement will not be displayed.

Regardless of the installation method, the use of this software is governed by a license agreement and you are responsible for complying with the license agreement.

To perform a quiet installation:

1. Open a command prompt **with administrator permissions**.
2. Run the following command:

```
Msiexec.exe /i spPowerPivot16.msi /q
```

Command Line Installation to include specific components

The Power Pivot for SharePoint 2016 Configuration tool is not required on every SharePoint server, however it is recommended to install it on at least two servers so the configuration tool is available when you need it.

When you install the spPowerPivot16.msi, you can use the command line options to install specific items, such as the data providers and not the Power Pivot for SharePoint 2016 Configuration tool. The following command line is an example of installing all components except the configuration tool:

```
Msiexec /i spPowerPivot16.msi AGREETOLICENSE="yes" ADDLOCAL=" SQL OLAPDM,SQL_ADOMD,SQL_AMO,SQLAS_SP_Common"
```

| OPTION | DESCRIPTION |
|----------------------------|--|
| Analysis_Server_SP_addin16 | Power Pivot for SharePoint 2016 Configuration |
| SQL OLAPDM | Analysis Services OLE DB Provider for SQL Server 2016 |
| SQL_ADOMD | ADOMD.NET provider |
| SQL_AMO | SQL Server 2016 Analysis Management Objects (AMO) provider |
| SQLAS_SP16_Common | Analysis Services common components for SharePoint 2016 |

Deploy the SharePoint Solution Files with the Power Pivot for SharePoint 2016 Configuration Tool

Three of the files copied to the hard drive by spPowerPivot16.msi are SharePoint solution files. The scope of one solution file is the Web application level while the scope of the other files is the farm level. The files are the following:

- PowerPivot16FarmSolution.wsp
- PowerPivot16WebApplicationSolution.wsp

The solution files are copied to the following folder:

ssInstallPathTools\PowerPivotTools\SPAddinConfiguration\Resources

Following the .msi installation, run the Power Pivot for SharePoint 2016 Configuration Tool to configure and deploy the solutions in the SharePoint farm.

To start the configuration tool:

From the Windows Start screen type "power" and in the Apps search results, select **Power Pivot for SharePoint 2016 Configuration**. Note that the search results may include two links because SQL Server setup installs separate Power Pivot configuration tools for SharePoint 2013 and SharePoint 2016. Make sure you start the Power Pivot for SharePoint 2016 Configuration tool.

Or

1. Go to **Start, All Programs**.
2. Select **Microsoft SQL Server 2017**.
3. Select **Configuration Tools**.
4. Select **Power Pivot for SharePoint 2016 Configuration**.

For more information on the configuration tool, see [Power Pivot Configuration Tools](#).

Uninstall or repair the add-in

Caution

If you uninstall **spPowerPivot16.msi** the data providers and the configuration tool are uninstalled. Uninstalling the data providers will cause the server to be unable to connect to Power Pivot.

You can uninstall or repair Power Pivot for SharePoint 2016 using one of the following methods:

1. **Windows control panel:** Select **Microsoft SQL Server 2017Power Pivot for SharePoint 2016**. Select either **Uninstall** or **Repair**.
2. Run the spPowerPivot16.msi and select the **Remove** option or the **Repair** option.

Command Line: To repair or uninstall Power Pivot for SharePoint 2016 using the command line, open a command prompt **with administrator permissions** and run one of the following commands:

- To Repair, run the following command:

```
msiexec.exe /f spPowerPivot16.msi
```

OR

- To uninstall, run the following command:

```
msiexec.exe /uninstall spPowerPivot16.msi
```

Install or Uninstall the Power Pivot for SharePoint Add-in (SharePoint 2013)

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Power Pivot for SharePoint 2013 is a collection of application server components and back-end services that provide Power Pivot data access in a SharePoint Server 2013 farm. The Power Pivot for SharePoint add-in (**spPowerpivot.msi**) is an installer package used to install the application server components.

- The add-in is not required for SharePoint 2010 deployments.
- The add-in is not required on a single server deployment that includes SharePoint 2013 and Analysis Services in SharePoint mode. The components installed by the add-in are included when you install an Analysis Services server in SharePoint mode. For diagrams of example deployments with the add-in, see [Deployment Topologies for SQL Server BI Features in SharePoint](#)

Note: This topic describes installing the Power Pivot solution files and Power Pivot for SharePoint 2013 Configuration tool. After the installation, see the following topic for information on the configuration tool and additional features, [Configure Power Pivot and Deploy Solutions \(SharePoint 2013\)](#).

For information on how to download **spPowerPivot.msi**, see [Microsoft® SQL Server® 2014 Power Pivot® for Microsoft SharePoint®](#).

Background

- **Application Server:** Power Pivot functionality in SharePoint 2013 includes using workbooks as a data source, scheduled data refresh, and the Power Pivot Management Dashboard.

Power Pivot for SharePoint 2013 is a Microsoft Windows Installer package (**spPowerpivot.msi**) that deploys Analysis Services client libraries and copies Power Pivot for SharePoint 2013 installation files to the computer. The installer does not deploy or configure Power Pivot features in SharePoint. The following components install by default:

- Power Pivot for SharePoint 2013. This component includes PowerShell scripts (.ps1 files), SharePoint solution packages (.wsp), and the Power Pivot for SharePoint 2013 configuration tool to deploy Power Pivot in a SharePoint 2013 farm.
- Microsoft OLE DB Provider for Analysis Services (MSOLAP).
- ADOMD.NET data provider.
- SQL Server Analysis Management Objects.

- **Backend services:** If you use Power Pivot for Excel to create workbooks that contain analytical data, you must have Excel Services configured with a BI server running Analysis Services in SharePoint mode to access that data in a server environment. You can run SQL Server Setup on a computer that has SharePoint Server 2013 installed, or on a different computer that has no SharePoint software. Analysis Services does not have any dependencies on SharePoint.

For more information on installing, uninstalling, and configuring the backend services, see the following:

Quiet Command Line Installation for scripting

You can use the **/q** or **/quiet** switches for a "quiet" installation that will not display any dialogs or warnings. The quiet installation is useful if you want to script the installation of the add-in.

IMPORTANT

If you use the **/q** switch for a silent command line installation, the end-user license agreement will not be displayed. Regardless of the installation method, the use of this software is governed by a license agreement and you are responsible for complying with the license agreement.

To perform a quiet installation:

1. Open a command prompt **with administrator permissions**.
2. Run the following command:

```
Msiexec.exe /i spPowerPivot.msi /q
```

Command Line Installation to include specific components

The Power Pivot for SharePoint 2013 Configuration tool is not required on every SharePoint server, however it is recommended to install it on at least two servers so the configuration tool is available when you need it.

When you install the **spPowerPivot.msi**, you can use the command line options to install specific items, such as the data providers and not the Power Pivot for SharePoint 2013 Configuration tool. The following command line is an example of installing all components except the configuration tool:

```
Msiexec /i spPowerPivot.msi AGREEtolicense="yes" ADDLOCAL=" SQL_Olapdm,SQL_Adomd,SQL_Amo,SQLAs_Sp_Common"
```

| OPTION | DESCRIPTION |
|--------------------------|---------------------------|
| Analysis_Server_SP_addin | Power Pivot Configuration |
| SQL_Olapdm | MSOLAP |
| SQL_Adomd | ADOMD.net provider |
| SQL_Amo | AMO provider |

| OPTION | DESCRIPTION |
|-----------------|---|
| SQLAS_SP_Common | Analysis Services common components for SharePoint 2013 |

Deploy the SharePoint Solution Files with the Power Pivot for SharePoint 2013 Configuration Tool

Three of the files copied to the hard drive by spPowerPivot.msi are SharePoint solution files. The scope of one solution file is the Web application level while the scope of the other files is the farm level. The files are the following:

- `PowerPivotFarmSolution.wsp`
- `PowerPivotFarm14Solution.wsp`
- `PowerPivotWebApplicationSolution.wsp`

The solution files are copied to the following folder:

```
ssInstallPathTools\PowerPivotTools\SPAddinConfiguration\Resources
```

Following the .msi installation, run the Power Pivot for SharePoint 2013 Configuration Tool to configure and deploy the solutions in the SharePoint farm.

To start the configuration tool:

From the Windows Start screen type "power" and in the Apps search results, click **Power Pivot for SharePoint 2013 Configuration**. Note that the search results may include two links because SQL Server setup installs separate Power Pivot configuration tools for SharePoint 2010 and SharePoint 2013. Make sure you start the Power Pivot for SharePoint 2013 Configuration tool.

Or

1. Go to **Start, All Programs**.
2. Click **Microsoft SQL Server 2017**.
3. Click **Configuration Tools**.
4. Click **Power Pivot for SharePoint 2013 Configuration**.

For more information on the configuration tool, see [Power Pivot Configuration Tools](#).

Uninstall or repair the add-in

Caution

If you uninstall **spPowerPivot.msi** the data providers and the configuration tool are uninstalled. Uninstalling the data providers will cause the server to be unable to connect to Power Pivot.

You can uninstall or repair Power Pivot for SharePoint 2013 using one of the following methods:

1. **Windows control panel:** Select **Microsoft SQL Server 2017Power Pivot for SharePoint 2013**. Click either **Uninstall** or **Repair**.

2. Run the spPowerPivot.msi and select the **Remove** option or the **Repair** option.

Command Line: To repair or uninstall Power Pivot for SharePoint 2013 using the command line, open a command prompt **with administrator permissions** and run one of the following commands:

- To Repair, run the following command:

```
msiexec.exe /f spPowerPivot.msi
```

OR

- To uninstall, run the following command:

```
msiexec.exe /uninstall spPowerPivot.msi
```

Configure Power Pivot and Deploy Solutions (SharePoint 2016)

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

This topics describes the deployment and configuration of middle-tier enhancements to the Power Pivot features in SharePoint Server 2016 including Power Pivot Gallery, Schedule data refresh, Management Dashboard, and data providers. Run **Power Pivot for SharePoint 2016 Configuration** tool to complete the following:

- Deploy SharePoint solution files.
- Create a Power Pivot service application.
- For information on backend services and installing a Analysis Services server in Power Pivot mode, see [Install Analysis Services in Power Pivot Mode](#).

For information on installing the Power Pivot for SharePoint 2016 Configuration tool, see [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2016\)](#).

Run Power Pivot for SharePoint 2016 configuration

Note: To complete the following steps, you must be a farm administrator. If you see an error message similar to the following:

- "The user is not a farm administrator. Please address the validation failures and try again."

Either login as the account that installed SharePoint or configure the setup account as the primary administrator of the SharePoint Central Administration Site.

1. On the **Start** menu, select **All Programs**, and then select **Microsoft SQL Server 2017**, select **Configuration Tools**, and then select **Power Pivot For SharePoint 2016 Configuration**. Tools is listed only when Power Pivot for SharePoint is installed on the local server.
2. Select **Configure or Repair Power Pivot for SharePoint** and then select **OK**.
3. The tool runs validation to verify the current state of Power Pivot and what steps are required to complete configuration. Expand the window to full size. You should see a button bar at the bottom of the window that includes **Validate**, **Run**, and **Exit** commands.
4. On the **Parameters** tab:
 - a. **Default Account UserName:** Enter a domain user account for the default account. This account will be used to provision services, including the Power Pivot service application pool. Do not specify a built-in account such as Network Service or Local System. The tool blocks configurations that specify built-in accounts.
 - b. **Database Server:** You can use SQL Server Database engine that is supported for the SharePoint farm.
 - c. **Passphrase:** Enter a passphrase. If you are creating a new SharePoint farm, the passphrase is used whenever you add a server or application to the SharePoint farm. If the farm already exists, enter the passphrase that allows you to add a server application to the farm.

- d. Click **Create Site Collection** in the left window. Note **Site URL** so you can reference it in later steps. If the SharePoint server is not already configured, then the configuration wizard defaults the web application, and site collection URLs to the root of `http://[ServerName]`. To modify the defaults review the following pages in the left window: **Create Default Web application** and **Deploy Web Application Solution**
5. Optionally, review the remaining input values used to complete each action. Click each action in the left window to see and review the details of the action. For more information about each one, see the section "Input values used to configure the server in [Configure or Repair Power Pivot for SharePoint 2010 \(Power Pivot Configuration Tool\)](#)" in this topic.
6. Optionally, remove any actions that you do not want to process at this time. For example, if you want to configure Secure Store Service later, select **Configure Secure Store Service**, and then clear the checkbox **Include this action in the task list**.
7. select **Validate** to check whether the tool has sufficient information to process the actions in the list. If you see validation errors, click the warnings in the left pane to see details of the validation error. Correct any validation errors and then select **Validate** again.
8. Select **Run** to process all of the actions in the task list. Note that **Run** becomes available after you validate the actions. If **Run** is not enabled, select **Validate** first.

For more information, see [Configure or Repair Power Pivot for SharePoint 2010 \(Power Pivot Configuration Tool\)](#)

Verify Power Pivot Configuration

Services:

1. In Central Administration, in System Settings, select **Manage services on server**.
2. Verify that **SQL Server Power Pivot System Service** is started.

Farm Feature:

1. In Central Administration, in System Settings, select **Manage farm features**.
2. Verify that **Power Pivot Integration Feature** is **Active**.

Site Collection Feature:

1. Browse to your site URL that was created by the Configuration tool.

Select **Settings**, and then click **Site Settings**.

Select **Site Collection Features**.

2. Verify that **Power Pivot Feature Integration for Site Collections** is **Active**.

Power Pivot Service Application:

1. In Central Administration, in the **Application Management**, select **Manage service applications**.
2. Verify the service application status is **started**. The default name is **Default Power Pivot Service Application**.

Select the name of the services application to open the Power Pivot Management Dashboard for the service application opens. On first use, the dashboard takes several minutes to load.

For more information, see [Verify a Power Pivot for SharePoint Installation](#).

Troubleshoot Issues

To assist in troubleshooting issues, it is a good idea to verify the diagnostic logging is enabled.

1. In SharePoint Central Administration, click **Monitoring** and then select **Configure usage and health data collection**.
2. Verify **Enable usage data collection** is selected.
3. Verify the following events are selected:
 - Definition of usage fields for Education telemetry
 - Power Pivot Connections
 - Power Pivot Load Data Usage
 - Power Pivot Query Usage
 - Power Pivot Unload Data Usage
4. Verify **Enable health data collection** is selected.
5. Select **OK**.

For more information on trouble shooting data refresh, see [Troubleshooting Power Pivot Data Refresh](https://social.technet.microsoft.com/wiki/contents/articles/3870.troubleshooting-powerpivot-data-refresh.aspx) (<https://social.technet.microsoft.com/wiki/contents/articles/3870.troubleshooting-powerpivot-data-refresh.aspx>).

For more information on the configuration tool, see [Power Pivot Configuration Tools](#).

Configure Power Pivot and Deploy Solutions (SharePoint 2013)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This topics describes the deployment and configuration of middle-tier enhancements to the Power Pivot features in SharePoint Server 2013 including Power Pivot Gallery, Schedule data refresh, Management Dashboard, and data providers. Run **Power Pivot for SharePoint 2013 Configuration** tool to complete the following:

- Deploy SharePoint solution files.
- Create a Power Pivot service application.
- Configure an Excel Services Application to use an Analysis Services server in SharePoint mode. For information on backend services and installing a Analysis Services server in SharePoint mode, see [Install Analysis Services in Power Pivot Mode](#).

For information on installing the Power Pivot for SharePoint 2013 Configuration tool, see [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2013\)](#)

Run Power Pivot for SharePoint 2013 configuration

Note: The SQL Server 2017 setup wizard installs two different configuration tools for Microsoft SQL Server 2016 Power Pivot for SharePoint. They each support a different version of SharePoint.

| NAME | DESCRIPTION |
|---|---|
| Power Pivot for SharePoint 2013 Configuration | SharePoint 2013 |
| Power Pivot Configuration Tool | SharePoint 2010 with SharePoint 2010 Service Pack 1 (SP1) |

Note: To complete the following steps, you must be a farm administrator. If you see an error message similar to the following:

- "The user is not a farm administrator. Please address the validation failures and try again."

Either login as the account that installed SharePoint or configure the setup account as the primary administrator of the SharePoint Central Administration Site.

1. On the **Start** menu, click **All Programs**, and then click **Microsoft SQL Server 2017**, click **Configuration Tools**, and then click **Power Pivot For SharePoint 2013 Configuration**. Tool is listed only when Power Pivot for SharePoint is installed on the local server.
2. Click **Configure or Repair Power Pivot for SharePoint** and then click **OK**.
3. The tool runs validation to verify the current state of Power Pivot and what steps are required to complete configuration. Expand the window to full size. You should see a button bar at the bottom of the window that includes **Validate**, **Run**, and **Exit** commands.
4. On the **Parameters** tab:
 - a. **Default Account UserName**: Enter a domain user account for the default account. This account

will be used to provision services, including the Power Pivot service application pool. Do not specify a built-in account such as Network Service or Local System. The tool blocks configurations that specify built-in accounts.

- b. **Database Server:** You can use SQL Server Database engine that is supported for the SharePoint farm.
 - c. **Passphrase:** Enter a passphrase. If you are creating a new SharePoint farm, the passphrase is used whenever you add a server or application to the SharePoint farm. If the farm already exists, enter the passphrase that allows you to add a server application to the farm.
 - d. **Power Pivot Server for Excel Services:** Type the name of an Analysis Services SharePoint mode server. In a single-server deployment, it is the same as the database server. [ServerName]\powerpivot
 - e. Click **Create Site Collection** in the left window. Note **Site URL** so you can reference it in later steps. If the SharePoint server is not already configured, then the configuration wizard defaults the web application, and site collection URLs to the root of http://[ServerName]. To modify the defaults review the following pages in the left window: **Create Default Web application** and **Deploy Web Application Solution**
5. Optionally, review the remaining input values used to complete each action. Click each action in the left window to see and review the details of the action. For more information about each one, see the section "Input values used to configure the server in [Configure or Repair Power Pivot for SharePoint 2010 \(Power Pivot Configuration Tool\)](#)" in this topic.
 6. Optionally, remove any actions that you do not want to process at this time. For example, if you want to configure Secure Store Service later, click **Configure Secure Store Service**, and then clear the checkbox **Include this action in the task list**.
 7. Click **Validate** to check whether the tool has sufficient information to process the actions in the list. If you see validation errors, click the warnings in the left pane to see details of the validation error. Correct any validation errors and then click **Validate** again.
 8. Click **Run** to process all of the actions in the task list. Note that **Run** becomes available after you validate the actions. If **Run** is not enabled, click **Validate** first.

For more information, see [Configure or Repair Power Pivot for SharePoint 2010 \(Power Pivot Configuration Tool\)](#)

Verify Power Pivot Configuration

Services:

1. In Central Administration, in System Settings, click **Manage services on server**.
2. Verify that **SQL Server Analysis Services** and **SQL Server Power Pivot System Service** are started.

Farm Feature:

1. In Central Administration, in System Settings, click **Manage farm features**.
2. Verify that **Power Pivot Integration Feature** is **Active**.

Site Collection Feature:

1. Browse to your site URL that was created by the Configuration tool.

Click **Settings**, and then click **Site Settings**.

Click **Site Collection Features**.

2. Verify that **Power Pivot Feature Integration for Site Collections** is **Active**.

Power Pivot Service Application:

1. In Central Administration, in the **Application Management**, click **Manage service applications**.
2. Verify the service application status is **started**. The default name is **Default Power Pivot Service Application**.

Click the name of the services application to open the Power Pivot Management Dashboard for the service application opens. On first use, the dashboard takes several minutes to load.

For more information, see [Verify a Power Pivot for SharePoint Installation](#).

Troubleshoot Issues

To assist in troubleshooting issues, it is a good idea to verify the diagnostic logging is enabled.

1. In SharePoint Central Administration, click **Monitoring** and then click **Configure usage and health data collection**.
2. Verify **Enable usage data collection** is selected.
3. Verify the following events are selected:
 - Definition of usage fields for Education telemetry
 - Power Pivot Connects
 - Power Pivot Load Data Usage
 - Power Pivot Query Usage
 - Power Pivot Unload Data Usage
4. Verify **Enable health data collection** is selected.
5. Click **OK**.

For more information on trouble shooting data refresh, see [Troubleshooting Power Pivot Data Refresh](#) (<https://social.technet.microsoft.com/wiki/contents/articles/3870.troubleshooting-powerpivot-data-refresh.aspx>).

For more information on the configuration tool, see [Power Pivot Configuration Tools](#).

Configure Analysis Services and Kerberos Constrained Delegation (KCD)

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: ✔ SQL Server Analysis Services ✖ Azure Analysis Services ✖ Power BI Premium

Kerberos constrained delegation (KCD) is an authentication protocol you can configure with Windows authentication to delegate client credentials from service to service throughout your environment. KCD requires additional infrastructure, for example a Domain Controller, and additional configuration of your environment. KCD is a requirement in some scenarios that involve Analysis Services and Power Pivot data with SharePoint 2016. In SharePoint 2016, Excel Services has moved outside the SharePoint farm to a separate and new server, the **Office Online Server**. Because the Office Online Server is separate, there is an increased need for a way to delegate client credentials in the typical two hop scenarios.

Overview

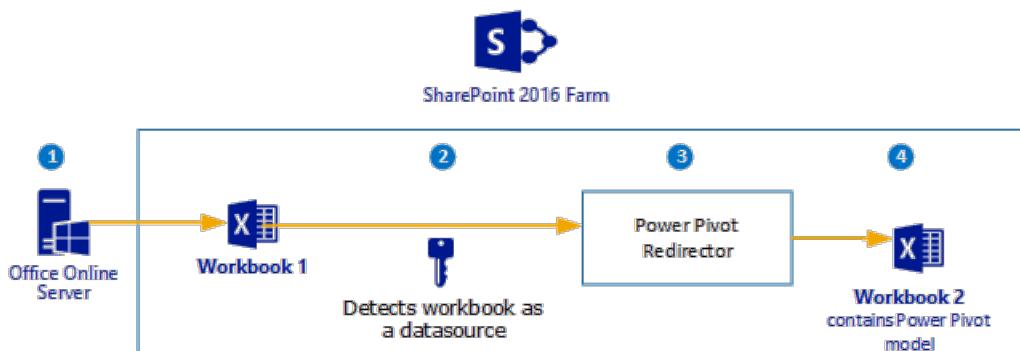

KCD enables an account to impersonate another account for the purpose of providing access to resources. The impersonating account would be a service account assigned to a web application or the computer account of a web server while the impersonated account would be a user account requiring access to resources. KCD operates at the service level, so that selected services on a server can be granted access by the impersonating account, while other services on the same server, or services on other servers are denied for access.

The sections in this topic review common scenarios with Analysis Services and Power Pivot where KCD is required as well as an example server deployment with a high level summary of what you need to install and configure. See the [More Information and community content](#) section for links to more detailed information on the technologies involved such as Domain Controllers and KCD.

Scenario 1: Workbook as data source (WDS).

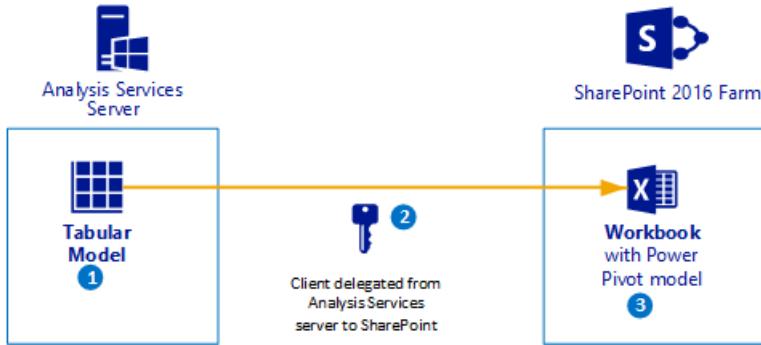

- ① Office Online Server opens an Excel workbook and ② detects a data connection to another workbook. Office Online Server sends a request to the Power Pivot Redirector Service ③ to open the second workbook and the data ④.

In this scenario, user credentials need to be delegated from the Office Online Server to the SharePoint Power Pivot Redirector Service in SharePoint.

Scenario 2: An Analysis Services Tabular model links to an Excel workbook

An Analysis Services Tabular model ⁽¹⁾ links to an Excel workbook which contains a Power Pivot model. In this scenario, when Analysis Services loads the Tabular model, Analysis Services detects the link to the workbook. When processing the model, Analysis Services sends a query request to SharePoint to load the workbook. In this scenario, client credentials do **not** need to be delegated from Analysis Services to SharePoint, however a client application can overwrite the data source information in an out-of-line binding. If the out-of-line binding request specifies to impersonate the current user, then the user credentials must be delegated, which requires KCD to be configured between Analysis Services and SharePoint.

Example deployment of KCD with Office Online Server and Analysis Services

This section describes an example deployment that uses four computers. The following sections summarize the key installation and configuration steps for each computer. Before you begin deployments, it is advised the computers are up to date with operating system patching and you know the computer names because they are needed in some of the configuration steps.

- Domain Controller
- SQL Server database engine and Analysis Services in Power Pivot mode. The instance of the database engine will be used for the SharePoint content databases.
- SharePoint server 2016
- Office Online Server

Domain Controller

The following is a summary of what to install for the domain controller (DC).

- **Role:** Active Directory Domain Services.
- **Role:** DNS Server
- **Feature:** .NET Framework 3.5 Features / .NET Framework 3.5
- **Feature:** Remote Server Administration Tools / Role Administration Tools
- Configure Active Directory to create a new Forest and join the computers to the domain. Before trying to add other computers to the private domain, you will need to configure the client computers DNS to the DC's IP address. On the DC machine, run `ipconfig /all` to get the IPv4 and IPv6 addresses for the next step.
- It is recommended you configure both IPv4 and IPv6 addresses. You can do this in Windows control panel:
 1. Click **Network and Sharing Center**

2. Click your Ethernet connection
3. Click **Properties**
4. Click **Internet Protocol Version 6 (TCP/IPv6)**
5. Click **Properties**
6. Click **Use the following DNS server addresses**
7. Type the IP address from the ipconfig command.
8. Click the **Advanced** button , click the **DNS** tab and verify the DNS suffixes are correct.
9. Click **Append these DNS Suffixes.**
10. Repeat the steps for IPv4.

- **Note:** you can join computers to the domain from Windows Control panel, in the System settings. For more information, see [How To Join Windows Server 2012 to a Domain](#).

2016 SQL Server Database engine and Analysis services in Power Pivot mode

The following is a summary of what to install on the SQL Server computer.

Tip In the SQL Server 2017 setup wizard, Analysis Services in Power Pivot mode is installed as part of the feature selection workflow.

1. Run the SQL Server 2017 setup wizard and from the feature selection page, click the database engine, Analysis Services, and the Management tools. In a later setup for the setup wizard you can specify the Power Pivot mode for Analysis Services.
2. For instance configuration, configure a named instance of "POWERPIVOT".
3. On the Analysis Services Configuration page, configure the Analysis Services server for **Power Pivot** mode and add the **computer name** of the Office Online Server to the list of Analysis Services server administrators. For more information, see [Install Analysis Services in Power Pivot Mode](#).
4. Note, by default the "Computer" object type is not included in the search. Click **Object Types...** to add the Computers object.

Object Types

Select the types of objects you want to find.

Object types:

| | |
|-------------------------------------|------------------------------|
| <input checked="" type="checkbox"/> | Built-in security principals |
| <input checked="" type="checkbox"/> | Service Accounts |
| <input checked="" type="checkbox"/> | Computers |
| <input checked="" type="checkbox"/> | Groups |
| <input checked="" type="checkbox"/> | Users |

5. Create the Service Principal Names (SPN) for the Analysis Services instance.

The following are useful SPN commands:

- List the SPN for a specific account name running the service of interest: `SetSPN -l <account-name>`
- Set a SPN for an account name that is running the service of interest:
`SetSPN -a <SPN> <account-name>`

- Delete a SPN from a specific account name running the service of interest:

```
SetSPN -D <SPN> <account-name>
```

- Search for duplicate SPNs: `SetSPN -X`

The SPN for the PowerPivot instance will be in the form of:

```
MSSQLSvc.3/\<Fully Qualified Domain Name (FQDN)>:POWERPIVOT
MSSQLSvc.3/<NetBIOS Name>:POWERPIVOT
```

Where the FQDN and NetBIOS names are the name of the machine that the instance resides on. These SPNs will be placed on the Domain Account that is being used for the service account. If you are using Network Service, Local System, or the Service ID, you will want to place the SPN on the domain machine account. If you are using a domain user account, you will place the SPN on that account.

6. Create the SPN for the SQL Browser service on the Analysis Services machine.

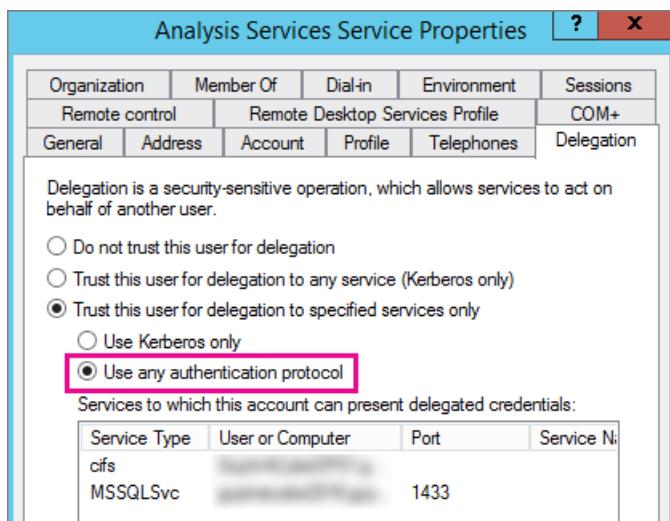

[Learn more](#)

7. **Configure constrained delegation** settings on the Analysis Services service account for any external source you will be refreshing from such as SQL Server, or Excel files. On the Analysis Services service account, we want to make sure the following are set.

Note: If you do not see the delegation tab for the account, within Active Directory Users and Computers, it is because there is no SPN on that account. You can add a fake SPN to get it to appear such as `my/spn`.

Trust this user for delegation to specified services only and **Use any authentication protocol**.

This is known as constrained delegation, and is required because the windows token will originate from a Claims to Windows Token Services (C2WTS) which requires constrained delegation with protocol transitioning.

You will also need to add the services that you will be delegating to. This will vary based on your environment.

Office Online Server

1. Install Office Online Server
2. **Configure Office Online Server** to connect to the Analysis Services server. Note, the Office Online Server computer account needs to be an administrator on the Analysis Services server. This was completed in a previous section of this topic, installing the Analysis Services server.
 - a. On the Office Online Server, open a PowerShell window with administrative privileges and run the

following command

- b. `New-OfficeWebAppsExcelBIServer -ServerId <AS instance name>`
- c. Sample: `New-OfficeWebAppsExcelBIServer -ServerId "MTGQLSERVER-13\POWERPIVOT"`

3. **Configure Active Directory** to allow the Office Online Server computer account to impersonate users to the SharePoint service account. So, set delegation property on principal running the Application Pool for SharePoint Web Services, on the Office Online Server: The PowerShell commands in this section require the Active Directory (AD) PowerShell objects.

- a. Get the Active Directory identity of the Office Online Server

```
$computer1 = Get-ADComputer -Identity [ComputerName]
```

find this Principal name is by looking at Task Manager / Details / w3wp.exe's User name. For example "svcSharePoint"

```
Set-ADUser svcSharePoint -PrincipalsAllowedToDelegateToAccount $computer1
```

- b. To verify the property was set correctly

```
Get-ADUser svcSharePoint -Properties PrincipalsAllowedToDelegateToAccount
```

4. **Configure constrained delegation** settings on the Office Online Server account to the Analysis Services Power Pivot instance. This should be the machine account that Office Online Server is running on. On the Office Online Service account, we want to make sure the following are set.

Note: If you do not see the delegation tab for the account, within Active Directory Users and Computers, it is because there is no SPN on that account. You can add a fake SPN to get it to appear such as `my/spn`.

Trust this user for delegation to specified services only and **Use any authentication protocol**.

This is known as constrained delegation, and is required because the windows token will originate from a Claims to Windows Token Services (C2WTS) which requires constrained delegation with protocol transitioning. You will then want to allow delegation to the MSOLAPSvc.3 and MSOLAPDisco.3 SPNs that we created above.

5. Setup Claims to windows token service (C2WTS) **This is needed for scenario 1**. For more information see [Claims to Windows Token Service \(c2WTS\) Overview](#).
6. **Configure constrained delegation** settings on the C2WTS service account. The settings should match what you did in step 4.

SharePoint Server 2016

The following is a summary of SharePoint Server installation.

1. Run SharePoint Pre-requisite installer
2. Run and SharePoint installation and select the **Single Server Farm** setup role.
3. Run the PowerPivot for SharePoint add-in (spPowerPivot16.msi). For more information, see [Install or Uninstall the Power Pivot for SharePoint Add-in \(SharePoint 2016\)](#)

4. Run the PowerPivot Configuration wizard. See [Power Pivot Configuration Tools](#).
5. Connect SharePoint to the Office Online Server. ([Configure_xlwac_on_SPO.ps1](#))
6. Configure SharePoint Authentication providers for Kerberos. **This is needed for scenario 1.** For more information, see [Plan for Kerberos authentication in SharePoint 2013](#).

Verify a Power Pivot for SharePoint Installation

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A Power Pivot for SharePoint instance that you install in a SharePoint farm is administered through SharePoint Central Administration. At a minimum, you can check pages in Central Administration and on SharePoint sites to verify that Power Pivot server components and features are available. However, to fully verify an installation, you must have a Power Pivot workbook that you can publish to SharePoint and access from a library. For testing purposes, you can publish a sample workbook that already contains Power Pivot data and use it to confirm that SharePoint integration is correctly configured.

Verify Central Administration Integration

To verify Power Pivot integration with Central Administration, do the following:

1. On the Start menu, click **All Programs**, open Microsoft SharePoint 2016 Products, or Microsoft SharePoint 2013 Products, and click **SharePoint 2016 Central Administration**, or **SharePoint 2013 Central Administration**.
2. Enter your user name and password, and then click **OK**.

Optionally, you can modify browser settings to avoid having to enter a user name and password each time you open Central Administration. To add Central Administration as a trusted site, do the following.

- a. In Internet Explorer, on the Tools menu, click **Internet options**.
- b. On the Security tab, in the **Select a zone to view or change security settings** section, click Trusted Sites, and then click Sites.
- c. Clear the **Require server verification ([https:](https://)) for all sites in this zone** checkbox.
- d. In **Add this Web site to the zone**, type the URL to your site, and then click **Add**.
- e. Click **Close**, and then click **OK**.

NOTE

SharePoint installation documentation includes additional instructions for working around proxy server errors and for disabling Internet Explorer Enhanced Security Configuration so that you can download and install updates. For more information, see the **Perform additional tasks** section in [Deploy a single server with SQL Server](#) on the Microsoft web site.

3. In Central Administration, in System Settings, click **Manage farm features**.
4. Verify that **Power Pivot Integration Feature** is **Active**.
5. In Central Administration, in System Settings, click **Manage services on server**.
6. Verify that **SQL Server Power Pivot System Service** are started.

In a multiple server SharePoint Farm, you may need to change the server you are viewing to validate that all of the servers you deployed Power Pivot to are running.

7. In Central Administration, in Application Management, click **Manage service applications**.

8. Click **Default Power Pivot Service Application** to open Power Pivot Management Dashboard for this application. On first use, the dashboard takes several minutes to load.

Alternatively, click the empty space next to **Default Power Pivot Service Application** to select the row, and click **Properties** to view the configuration settings for this service application. You can modify both configuration settings and application properties to change your server configuration. For more information about these settings, see [Create and Configure a Power Pivot Service Application in Central Administration](#).

Verify Integration at the Site Level

To verify Power Pivot integration with a SharePoint site, do the following:

1. In a browser, open the Web application you created. If you used default values, you can specify `http://\<your computer name>` in the URL address.
2. Verify that Power Pivot data access and processing features are available in the application. You can do this by verifying the presence of Power Pivot-provided library templates:
 - a. Select **Site Contents**.
 - b. In the app list, you should see **Data Feed Library** and **Power Pivot Gallery**. These library templates are provided by the Power Pivot feature and will be visible in the Libraries list if the feature is integrated correctly.

Verify Data Access on the Server

To verify Power Pivot data access on the server, do the following:

1. [Download](#) the Picnic data sample that accompanies a Reporting Services tutorial. You will use the sample workbook in this download to verify Power Pivot data access. Extract the files.
2. Upload the Excel workbook (.xlsx) to Shared Documents. The workbook contains embedded Power Pivot data.
3. Click on the document to open it from the library.
4. Click on a slicer or filter at the top of the workbook. Month, color, and type are slicers in this workbook. Clicking a slicer starts a Power Pivot query and proves that your server is operational. The server will load Power Pivot data in the background and return the results.
5. Go back to the library. Select the down arrow to the right of the workbook, and then click **Launch Power View**. This step confirms that the Power View feature in Reporting Services is operational. If you did not install Reporting Services, skip this step.

In the next step, you will connect to the server in Management Studio to verify the data is loaded and cached.

6. Start SQL Server Management Studio from the **Microsoft SQL Server 2017** program group in the Start menu. If this tool is not installed on your server, you can skip ahead to the last step to confirm the presence of cached files.
7. In Server Type, select **Analysis Services**.
8. In Server Name, enter `<server-name>\powerpivot`, where `<server-name>` is the name of the computer that has the Power Pivot for SharePoint installation.
9. Click **Connect**. This verifies that the Analysis Services server is available.

10. In Object Explorer, you can click **Databases** to view the list of Power Pivot data files that are loaded.
11. On the computer file system, check the following folder to determine whether files are cached to disk. The presence of cached files is further verification that your deployment is operational. To view the file cache, go to the <drive>:\Program Files\Microsoft SQL Server\<nnn\MSAS13.POWERPIVOT\OLAP\Backup\Sandboxes\Default Power Pivot Service Application folder. Each cached database is stored in its own folder, using a GUID-based naming convention to ensure a unique name.

Use PowerShell to Verify Power Pivot for SharePoint

9/12/2019 • 17 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

No Power Pivot for SharePoint installation or recovery operation is complete without a solid verification test pass that confirms your services and data are operational. In this article, we show you how to perform these steps using Windows PowerShell. We put each step into its own section so that you can go straight to specific tasks. For example, run the script in the [Databases](#) section of this topic to verify the name of the service application and content databases if you want to schedule them for maintenance or backup.

A full PowerShell script is included at the bottom of the topic. Use the full script as a starting point to build a custom script for auditing your full Power Pivot for SharePoint deployment.

Prepare your PowerShell environment

The steps in this section prepare your PowerShell environment. The steps may not be required, depending on how your scripting environment is currently configured.

PowerShell Permissions

Open a Powershell window or the PowerShell ISE (Integrated Scripting Environment) with **administrative privileges**. If you do not have administrative privileges when you run commands, you will see an error message similar to the following:

Get-SPLogEvent : You need to have computer **administrator privileges** to run this cmdlet.

SharePoint and Power Pivot for SharePoint Module

If you see an error message similar to the following when you run SharePoint related cmdlets, run the Add-PSSnapin command:

The term 'Get-PowerPivotSystemService' **is not recognized as the name of a cmdlet**, function, script file, or operable program. Check the spelling of the name, or if a path was included, verify that the path is correct and try again.

```
Add-PSSnapin Microsoft.Sharepoint.Powershell -EA 0
```

Windows PowerShell

For more information on the PowerShell ISE, see [Introducing the Windows PowerShell ISE](#) and [Use Windows PowerShell to administer SharePoint 2013](#).

You can optionally verify a majority of the components in Central Administration, using the Power Pivot management dashboard. To open the dashboard in Central Administration, click **General Application Settings**, and then click **Management Dashboard** in the **Power Pivot**. For more information on the dashboard, see [Power Pivot Management Dashboard and Usage Data](#).

Symptoms and Recommended Actions

The following table is a list of symptoms or issues and the suggested section of this topic to consult to help you resolve the issue.

| SYMPTOM | SEE SECTION |
|---|---|
| Data refresh is not running | See the section Timer Jobs and verify the Online Power Pivot Data Refresh Timer Job is online. |
| Management dashboard data is old | See the section Timer Jobs and verify the Management Dashboard Processing Timer Job is online. |
| Some portions of the Management Dashboard | If you install Power Pivot for SharePoint into a farm that has the topology of Central Administration, without Excel Services or Power Pivot for SharePoint, you must download and install the Microsoft ADOMD.NET client library if you want full access to the built-in reports in the Power Pivot management dashboard. Some reports in the dashboard use ADOMD.NET to access internal data that provides reporting data on Power Pivot query processing and server health in the farm. See the section ADOMD.Net client Library and the topic Install ADOMD.NET on Web Front-End Servers Running Central Administration . |

Analysis Services Windows Service

The script in this section verifies the instance of Analysis Services in SharePoint mode. Verify the service is **running**.

```
get-service | select name, displayname, status | where {$_.Name -eq "msolap\$powerpivot"} | format-table -property * -autosize | out-default
```

Example output

| Name | DisplayName | Status |
|--------------------|---|---------|
| --- | ----- | ----- |
| MSOLAP\$POWERPIVOT | SQL Server Analysis Services (POWERPIVOT) | Running |

PowerPivotSystemService and PowerPivotEngineService

The scripts in this section verify the Power Pivot for SharePoint system services. There is one system service for a SharePoint 2013 deployment and two services for a SharePoint 2010 deployment.

PowerPivotSystemService

Verify the Status is **Online**.

```
Get-PowerPivotSystemService | select typename, status, applications, farm | format-table -property * -autosize | out-default
```

Example output

| TypeName | Status Applications | Farm |
|---|---|---|
| SQL Server PowerPivot Service Application | Online {Default PowerPivot Service Application} | SPFarm
Name=SharePoint_Config_77d8ab0744a34e8aa27c806a2b8c760c |

PowerPivotEngineService

NOTE

Skip this script if you are using SharePoint 2013. The PowerPivotEngineService is not part of a SharePoint 2013 deployment. If you run the Get-PowerPivotEngineService cmdlet on SharePoint 2013, you will see an error message similar to the following. This error message is returned even if you have run the Add-PSSnapin command described in the prerequisites section of this topic.

The term 'Get-PowerPivotEngineService' is not recognized as the name of a cmdlet

In a SharePoint 2010 deployment, verify the status is **Online**.

```
Get-PowerPivotEngineService | select typename, status, name, instances, farm | format-table -property * -autosize | out-default
```

Example output

```
TypeName : SQL Server Analysis Services
Status   : Online
Name     : MSOLAP$POWERPIVOT
Instances : {POWERPIVOT}
Farm     : SPFarm Name=SharePoint_Config
```

Power Pivot Service Application(s) and proxies

Verify the status is **Online**. The Excel Services Application does not use a service application database and therefore the cmdlet does not return a database name. Note the database used by the Power Pivot service application so you can verify the database is online in the database section later in this topic.

Power Pivot and Excel Service Application(s)

For a SharePoint 2010 deployment, verify the status is **Online**.

```
Get-PowerPivotServiceApplication | select typename,name, status, unattendedaccount, applicationpool, farm, database
Get-SPEexcelServiceApplication | select typename, DisplayName, status
```

Example output

```

TypeName      : PowerPivot Service Application
Name          : PowerPivotServiceApplication1
Status        : Online
UnattendedAccount : PowerPivotUnattendedAccount
ApplicationPool   : SPIisWebServiceApplicationPool Name=sqlbi_serviceapp
Farm          : SPFarm Name=SharePoint_Config
Database       : GeminiServiceDatabase Name=PowerPivotServiceApplication1_19648f3f2c944e27acdc6c20aab8487a

TypeName      : Excel Services Application Web Service Application
DisplayName  : Excel Services Application
Status        : Online

```

Service Application Pool

NOTE

The following code sample first returns the applicationpool property of the default Power Pivot for SharePoint service application. The name is parsed from the string and used to get the status of the application pool object.

Verify the Status is **Online**. If the status is not Online or you see "http error" when you browse the Power Pivot site, verify the identity credentials in the IIS application pools are still correct. The IIS pool name will be the value of the ID property returned by the Get-SPServiceApplicationPool command.

```

$poolname=[string](Get-PowerPivotServiceApplication | select -property applicationpool)
$position=$poolname.lastindexof("=")
$poolname=$poolname.substring($position+1)
$poolname=$poolname.substring(0,$poolname.length-1)
Get-SPServiceApplicationPool | select name, status, processaccountname, id | where {$_.Name -eq $poolname} |
format-table -property * -autosize | out-default

```

Example output

| Name | Status | ProcessAccountName | Id |
|--------------------------------|--------|--------------------|--------------------------------------|
| SharePoint Web Services System | Online | DOMAIN\account | 89b50ec3-49e3-4de7-881a-2cec4b8b73ea |

The application pool can also be verified on the Central Administration page **Manage Service Applications**. Click the name of the service application and then click **properties** in the ribbon.

Power Pivot and Excel Service Application proxies

Verify the Status is **Online**.

```

Get-SPServiceApplicationProxy | select typename, status, unattendedaccount, displayname | where {$_.TypeName -like "*powerpivot*" -or $_.TypeName -like "*excel services*"} | format-table -property * -autosize | out-default

```

Example output

| TypeName | Status | UnattendedAccount | DisplayName |
|---|--------|-----------------------------|----------------|
| PowerPivot Service Application Proxy
PowerPivotServiceApplication1 | Online | PowerPivotUnattendedAccount | |
| Excel Services Application Web Service Application Proxy
Online
Application | | | Excel Services |

Databases

The following script returns the status of the service application databases and all content databases. Verify the status is **Online**.

```
Get-SPDatabase | select name, status, server, typename | where {$_.TypeName -eq "content database" -or  
$_.TypeName -like "*Gemini*"} | format-table -property * -autosize | out-default
```

Example output

| Name | Status | Server |
|--|--------|--------------------------|
| TypeName | | |
| ---- | ----- | ----- |
| --- | | |
| DefaultPowerPivotServiceApplicationDB-38422181-2b68-4ab2-b2bb-9c00c39e5a5e | Online | SPServer Name=TESTSERVER |
| Microsoft.AnalysisServices.SPAddin.GeminiServiceDatabase | | |
| DefaultWebApplicationDB-f0db1a8e-4c22-408c-b9b9-153bd74b0312 | Online | TESTSERVER\POWERPIVOT |
| Content Database | | |
| SharePoint_Admin_3cadf0b098bf49e0bb15abd487f5c684 | Online | TESTSERVER\POWERPIVOT |
| Content Database | | |

SharePoint Features

Verify the site, web, and farm features are online.

```
Get-SPFeature | select displayname, status, scope, farm | where {$_.displayName -like "*powerpivot*"} | format-table -property * -autosize | out-default
```

Example output

| DisplayName | Status | Scope | Farm |
|-----------------|--------|-------|-------------------------------|
| PowerPivotSite | Online | Site | SPFarm Name=SharePoint_Config |
| PowerPivotAdmin | Online | Web | SPFarm Name=SharePoint_Config |
| PowerPivot | Online | Farm | SPFarm Name=SharePoint_Config |

Timer Jobs

Verify the Time Jobs are **Online**. The Power Pivot EngineService is not installed on SharePoint 2013, therefore the script will not list EngineService timer jobs in a SharePoint 2013 deployment.

```
Get-SPTimerJob | where {$_.service -like "*power*" -or $_.service -like "*mid*"} | select status, displayname, LastRunTime, service | format-table -property * -autosize | out-default
```

Example output

| Service | Status DisplayName | LastRunTime |
|---|--------------------|---------------------|
| Online Health Analysis Job (Daily, SQL Server Analysis Services, All Servers) | | 4/9/2014 12:00:01 |
| AM EngineService Name=MSOLAP\$POWERPIVOT | | |
| Online Health Analysis Job (Hourly, SQL Server Analysis Services, All Servers) | | 4/9/2014 1:00:01 PM |
| EngineService Name=MSOLAP\$POWERPIVOT | | |
| Online Health Analysis Job (Weekly, SQL Server Analysis Services, All Servers) | | 4/6/2014 12:00:10 |
| AM EngineService Name=MSOLAP\$POWERPIVOT | | |
| Online PowerPivot Management Dashboard Processing Timer Job | | 4/8/2014 3:45:38 AM |
| MidTierService | | |
| Online PowerPivot Health Statistics Collector Timer Job | | 4/9/2014 1:00:12 PM |
| MidTierService | | |
| Online PowerPivot Data Refresh Timer Job | | 4/9/2014 1:09:36 PM |
| MidTierService | | |
| Online Health Analysis Job (Daily, SQL Server PowerPivot Service Application, All Servers) | 4/9/2014 12:00:00 | |
| AM MidTierService | | |
| Online Health Analysis Job (Daily, SQL Server PowerPivot Service Application, Any Server) | 4/9/2014 12:00:00 | |
| AM MidTierService | | |
| Online Health Analysis Job (Weekly, SQL Server PowerPivot Service Application, All Servers) | 4/6/2014 12:00:03 | |
| AM MidTierService | | |
| Online Health Analysis Job (Weekly, SQL Server PowerPivot Service Application, Any Server) | 4/6/2014 12:00:03 | |
| AM MidTierService | | |
| Online PowerPivot Setup Extension Timer Job | | 4/1/2014 1:40:31 AM |
| MidTierService | | |

Health Rules

There are fewer rules in a SharePoint 2013 deployment. For a full list of rules for each SharePoint environment and an explanation of how to use the rules, see [Configure Power Pivot Health Rules](#).

```
Get-SPHealthAnalysisRule | select name, enabled, summary | where {$_.summary -like "*power*"} | format-table -property * -autosize | out-default
```

Example output

| Name | Enabled Summary |
|-------------------------------|--|
| SecondaryLogonHealthRule | True PowerPivot: Secondary Logon service (seclogon) is disabled |
| DataRefreshTimerJobHealthRule | True PowerPivot: The PowerPivot Data Refresh timer job is disabled. |
| ASUsageLoadHealthRule | True PowerPivot: The ratio of load events to connections is too high. |
| ASMiniDumpHealthRule | True PowerPivot: One or more minidump files were found in the Logs directory, indicating a program crash |
| ASUsageCubeRule | True PowerPivot: Usage data is not getting updated at the expected frequency. |
| ASADOMDNETHHealthRule | True PowerPivot: ADOMD.NET is not installed on a standalone WFE that is configured for central admin |
| MidTierAcctReadPermissionRule | True PowerPivot: MidTier process account should have 'Full Read' permission on all associated SPWebApplications. |

Windows and ULS Logs

Windows event log

The following command will search the windows event log for events related to the instance of Analysis Services in SharePoint mode. For information on disabling events or changing the event level, see [Configure and View SharePoint Log Files and Diagnostic Logging \(Power Pivot for SharePoint\)](#)

Service Name: MSOLAP\$POWERPIVOT

Display name in Windows Services: SQL Server Analysis Services (POWERPIVOT)

```
Get-EventLog "application" | Where-Object {$_ .source -like "msolap`$powerpivot*"} | select timegenerated, entrytype , source, message | format-table -property * -autosize | out-default
```

Example output

| TimeGenerated | EntryType | Source | Message |
|----------------------|-------------|--------------------|--|
| 4/16/2014 1:45:19 PM | Information | MSOLAP\$POWERPIVOT | Software usage metrics are disabled. |
| 4/16/2014 1:45:19 PM | Information | MSOLAP\$POWERPIVOT | Service started. Microsoft SQL Server Analysis Services 64 Bit Evaluation (x64) RTM 12.0.1997.5. |
| 4/16/2014 1:45:18 PM | Information | MSOLAP\$POWERPIVOT | The flight recorder was started. |
| 4/14/2014 6:45:37 PM | Information | MSOLAP\$POWERPIVOT | Software usage metrics are disabled. |

SharePoint ULS Log, last 48 hours

The following command will return Power Pivot messages from the ULS log that were created in the last 48 hours. Adjust the addhours parameter for your need.

```
Get-SPLogEvent -starttime(get-date).addhours(-48) | Where-Object {$_ .Area -eq "powerpivot service" -and $_ .level -eq "high"} | select timestamp, area, category, eventid,level, message| format-table -property * -autosize | out-default
```

The following variation of the command only returns log events for the **data refresh** category.

```
Get-SPLogEvent -starttime(get-date).addhours(-48) | Where-Object {$_ .category -eq "data refresh" -and $_ .level -eq "high"} | select timestamp, area, category, eventid, level, correlation, message
```

Example output

```

MSOLAP Provider

Verify the provider MSOLAP provider. SQL Server 2012 (11.x) and SQL Server 2014 (12.x) Power Pivot require MSOLAP.5.

```
$excelApp=Get-SPExcelServiceApplication
get-spexceldatatypeprovider -ExcelServiceApplication $excelApp |select providerid,providerstype,description | where
{$_._providerid -like "msolap*"} | format-table -property * -autosize | out-default
```

Example output

| ProviderId | ProviderType | Description |
|------------|--------------|--|
| MSOLAP | Oledb | Microsoft OLE DB Provider for OLAP Services |
| MSOLAP.3 | Oledb | Microsoft OLE DB Provider for OLAP Services 9.0 |
| MSOLAP.4 | Oledb | Microsoft OLE DB Provider for OLAP Services 10.0 |
| MSOLAP.5 | Oledb | Microsoft OLE DB Provider for OLAP Services 11.0 |

For more information, see [Install the Analysis Services OLE DB Provider on SharePoint Servers](#) and [Add MSOLAP.5 as a Trusted Data Provider in Excel Services](#).

ADOMD.Net client Library

```
get-wmiobject -class win32_product | Where-Object {$_._name -like "*ado*"} | select name, version, vendor |
format-table -property * -autosize | out-default
```

Example output

| name | version | vendor |
|---|--------------|-----------------------|
| Microsoft SQL Server 2008 Analysis Services ADOMD.NET | 10.1.2531.0 | Microsoft Corporation |
| Microsoft SQL Server 2005 Analysis Services ADOMD.NET | 9.00.1399.06 | Microsoft Corporation |

For more information, see [Install ADOMD.NET on Web Front-End Servers Running Central Administration](#).

Health Data Collection Rules

Verify the **Status** is Online and **Enabled** is True.

```
get-spusagedefinition | select name, status, enabled, tablename, DaysToKeepDetailedData | where {$_.name -like "powerpivot*"} | format-table -property * -autosize | out-default
```

Example output

| Name | Status | Enabled | TableName | DaysToKeepDetailedData |
|------------------------------|--------|---------|-----------------------------|------------------------|
| PowerPivot Connections | Online | True | AnalysisServicesConnections | 14 |
| PowerPivot Load Data Usage | Online | True | AnalysisServicesLoads | 14 |
| PowerPivot Query Usage | Online | True | AnalysisServicesRequests | 14 |
| PowerPivot Unload Data Usage | Online | True | AnalysisServicesUnloads | 14 |

For more information, see [Power Pivot Usage Data Collection](#).

Solutions

If the other components are online then you can skip verifying the solutions. If however the Health rules are missing, verify the two solutions exist and showed Verify the two Power Pivot solutions are **Online** and **Deployed**.

```
get-spsolution | select name, status, deployed, DeploymentState, DeployedServers | where {$_.Name -like "*powerpivot*"} | format-table -property * -autosize | out-default
```

Example output SharePoint 2013

| Name | Status | Deployed | DeploymentState | DeployedServers |
|--------------------------------------|--------|----------|------------------------|-----------------|
| powerpivotfarm14solution.wsp | Online | True | GlobalDeployed | {UETESTA00} |
| powerpivotfarmsolution.wsp | Online | True | GlobalDeployed | {UETESTA00} |
| powerpivotwebapplicationsolution.wsp | Online | True | WebApplicationDeployed | {UETESTA00} |

Example output SharePoint 2010

| Name | Status | Deployed | DeploymentState | DeployedServers |
|----------------------|--------|----------|------------------------|------------------|
| powerpivotfarm.wsp | Online | True | GlobalDeployed | {uesql11spoint2} |
| powerpivotwebapp.wsp | Online | True | WebApplicationDeployed | {uesql11spoint2} |

For more information on how to deploy SharePoint solutions, see [Deploy solution packages \(SharePoint Server 2010\)](#).

Manual Verification Steps

This section describes verification steps that cannot be completed with PowerShell cmdlets.

Verify Analysis Services cumulative update build version

7/16/2019 • 2 minutes to read • [Edit Online](#)

Beginning with SQL Server 2017, the Analysis Services build version number and SQL Server Database Engine build version number do not match. While both Analysis Services and the Database Engine use the same installer, the build systems each use are separate.

In some cases, it may be necessary to verify if a Cumulative Update (CU) build package has been applied and Analysis Services components have been updated. You can verify by comparing the build version numbers of Analysis Services component files installed on your computer with the build version numbers for a particular CU.

Verify component file version

To verify component file version,

1. Go to [SQL Server 2017 build versions](#).
2. In **SQL Server 2017 cumulative update (CU) builds**, click the **Knowledge Base Number** for the build you want to verify.
3. In the **Cumulative Update (#) for SQL Server 2017** article, in the **Cumulative Update package information** section, expand **Cumulative update package file information**.
4. In the **SQL Server 2017 Analysis Services** table, check the File version for the **msmdsrv.exe** component file. If the CU has been applied, the file version number should match the msmdsrv.exe file installed on your computer.

Post-install Configuration (Analysis Services)

10/25/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After installing Analysis Services, further configuration is required to make the server fully operational and available for general use. This section introduces the additional tasks that complete the installation. Depending on connection requirements, you might also need to configure authentication (see [Connect to Analysis Services](#)).

Later, additional work will be required once you have databases that are ready to deploy. Namely, you will need to configure role memberships on the database to grant user access to the data, design a database backup and recovery strategy, and determine whether you need a scheduled processing workload to refresh data at regular intervals.

Instance Configuration

Analysis Services is a replicable service, meaning you can install multiple instances of the service on a single server. Each additional instance is installed separately as a named instance, using SQL Server Setup, and configured independently to support its intended purpose. For example, a development server might run Flight Recorder or use default values for data storage that you might otherwise change on servers supporting production workloads. Another example that calls for adjusting system configuration is installing Analysis Services instance on hardware shared by other services. When hosting multiple data-intensive applications on the same hardware, you might want to configure server properties that lower the memory thresholds to optimize available resources across all of the applications.

Post-installation Tasks

| LINK | TASK DESCRIPTION |
|--|---|
| Configure the Windows Firewall to Allow Analysis Services Access | Create an inbound rule in Windows Firewall so that requests can be routed through the TCP port used by the Analysis Services instance. This task is required. No one can access Analysis Services from a remote computer until an inbound firewall rule is defined. |
| Grant server admin rights to an Analysis Services instance | During installation, you had to add at least one user account to the Administrator role of the Analysis Services instance. Administrative permissions are required for many routine server operations, such as processing data from external relational databases. Use the information in this topic to add or modify the membership of the Administrator role. |
| Configure antivirus software on computers running SQL Server | You might need to configure scanning software, such as antivirus and antispyware applications, to exclude SQL Server folders and file types. If scanning software locks a program or data file when Analysis Services needs to use it, service disruption or data corruption can occur. |

| LINK | TASK DESCRIPTION |
|--|--|
| Configure Service Accounts (Analysis Services) | During installation, the Analysis Services service account was provisioned, with appropriate permissions to allow controlled access to program executables and database files. As a post-installation task, you should now consider whether to allow the use of the service account when performing additional tasks. Both processing and query workloads can be executed under the service account. These operations succeed only when the service account has appropriate permissions. |
| Register an Analysis Services Instance in a Server Group | SQL Server Management Studio (SSMS) lets you create server groups for organizing your SQL Server instances. Scalable deployments consisting of multiple server instances are easier to manage in server groups. Use the information in this topic to organize Analysis Services instances into groups in SSMS. |
| Determine the Server Mode of an Analysis Services Instance | During installation, you chose a server mode that determines the type of model (multidimensional or tabular) that runs on the server. If you are unsure of the server mode, use the information in this topic to determine which mode was installed. |
| Rename an Analysis Services Instance | A descriptive name can help you distinguish among multiple instances having different server modes, or among instances primarily used by departments or teams in your organization. If you want to change the instance name to one that helps you better manage your installations, use the information in this topic to learn how. |

Next Steps

Learn how to connect to Analysis Services from Microsoft applications or custom applications using the client libraries. Depending on your solution requirements, you might also need to configure the service for Kerberos authentication. Connections that must cross domain boundaries will require HTTP access. See [Connect to Analysis Services](#) for instructions about the next steps.

Configure the Windows Firewall to Allow Analysis Services Access

7/16/2019 • 15 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

An essential first step in making Analysis Services or Power Pivot for SharePoint available on the network is to determine whether you need to unblock ports in a firewall. Most installations will require that you create at least one in-bound firewall rule that allows connections to Analysis Services.

Firewall configuration requirements vary depending on how you installed Analysis Services:

- Open TCP port 2383 when installing a default instance or creating an Analysis Services failover cluster.
- Open TCP port 2382 when installing a named instance. Named instances use dynamic port assignments. As the discovery service for Analysis Services, SQL Server Browser service listens on TCP port 2382 and redirects the connection request to the port currently used by Analysis Services.
- Open TCP port 2382 when installing Analysis Services in SharePoint mode to support Power Pivot for SharePoint 2013. In Power Pivot for SharePoint 2013, the Analysis Services instance is external to SharePoint. Inbound requests to the named 'Power Pivot' instance originate from SharePoint web applications over a network connection, requiring an open port. As with other Analysis Services named instances, create an inbound rule for SQL Server Browser service on TCP 2382 to allow access to Power Pivot for SharePoint.
- For Power Pivot for SharePoint 2010, do not open ports in Windows Firewall. As an add-in to SharePoint, the service uses ports configured for SharePoint and makes only local connections to the Analysis Services instance that loads and queries Power Pivot data models.
- For Analysis Services instances running on Windows Azure Virtual Machines, use alternate instructions for configuring server access. See [SQL Server Business Intelligence in Windows Azure Virtual Machines](#).

Although the default instance of Analysis Services listens on TCP port 2383, you can configure the server to listen on a different fixed port, connecting to the server in this format: <servername>:<portnumber>.

Only one TCP port can be used by an Analysis Services instance. On computers having multiple network cards or multiple IP addresses, Analysis Services listens on one TCP port for all IP addresses assigned or aliased to the computer. If you have specific multi-port requirements, consider configuring Analysis Services for HTTP access. You can then set up multiple HTTP endpoints on whatever ports you choose. See [Configure HTTP Access to Analysis Services on Internet Information Services \(IIS\) 8.0](#).

This topic contains the following sections:

- [Check port and firewall settings for Analysis Services](#)
- [Configure Windows Firewall for a default instance of Analysis Services](#)
- [Configure Windows Firewall access for a named instance of Analysis Services](#)
- [Port configuration for an Analysis Services cluster](#)
- [Port configuration for Power Pivot for SharePoint](#)
- [Use a fixed port for a default or named instance of Analysis Services](#)

For more information about the default Windows firewall settings, and a description of the TCP ports that affect the Database Engine, Analysis Services, Reporting Services, and Integration Services, see [Configure the Windows Firewall to Allow SQL Server Access](#).

Check port and firewall settings for Analysis Services

On the Microsoft Windows operating systems that are supported by SQL Server 2017, Windows Firewall is on by default and is blocking remote connections. You must manually open a port in the firewall to allow inbound requests to Analysis Services. SQL Server Setup does not perform this step for you.

Port settings are specified in the msmdsrv.ini file and in the General properties page of an Analysis Services instance in SQL Server Management Studio. If **Port** is set to a positive integer, the service is listening on a fixed port. If **Port** is set to 0, the service is listening on port 2383 if it is the default instance or on a dynamically assigned port if it is a named instance.

Dynamic port assignments are only used by named instances. The **MSOLAP\$InstanceName** service determines which port to use when it starts up. You can determine the actual port number in use by a named instance by doing the following:

- Start Task Manager and then click **Services** to get the PID of the **MSOLAP\$InstanceName**.
- Run **netstat -ao -p TCP** from the command line to view the TCP port information for that PID.
- Verify the port by using SQL Server Management Studio and connect to an Analysis Services server in this format: <IPAddress>:<portnumber>.

Although an application might be listening on a specific port, connections will not succeed if a firewall is blocking access. In order for connections to reach a named Analysis Services instance, you must unblock access to either msmdsrv.exe or the fixed port on which it is listening in the firewall. The remaining sections in this topic provide instructions for doing so.

To check whether firewall settings are already defined for Analysis Services, use Windows Firewall with Advanced Security in Control Panel. The Firewall page in the Monitoring folder shows a complete list of the rules defined for the local server.

Note that for Analysis Services, all firewall rules must be manually defined. Although Analysis Services and SQL Server Browser reserve ports 2382 and 2383, neither the SQL Server setup program nor any of the configuration tools define firewall rules that allow access to either the ports or the program executable files.

Configure Windows Firewall for a default instance of Analysis Services

The default instance of Analysis Services listens on TCP port 2383. If you installed the default instance and want to use this port, you only need to unblock inbound access to TCP port 2383 in Windows Firewall to enable remote access to the default instance of Analysis Services. If you installed the default instance but want to configure the service to listen on a fixed port, see [Use a fixed port for a default or named instance of Analysis Services](#) in this topic.

To verify whether the service is running as the default instance (MSSQLServerOLAPService), check the service name in SQL Server Configuration Manager. A default instance of Analysis Services is always listed as **SQL Server Analysis Services (MSSQLSERVER)**.

NOTE

Different Windows operating systems provide alternative tools for configuring Windows Firewall. Most of these tools let you choose between opening a specific port or program executable. Unless you have a reason for specifying the program executable, we recommend that you specify the port.

When specifying an inbound rule, be sure to adopt a naming convention that allows you to easily find the rules later (for example, **SQL Server Analysis Services (TCP-in) 2383**).

Windows Firewall with Advanced Security

1. On Windows 7 or Windows Vista, in Control Panel, click **System and Security**, select **Windows Firewall**, and then click **Advanced settings**. On Windows Server 2008 or 2008 R2, open Administrator Tools and click **Windows Firewall with Advanced Security**. On Windows Server 2012, open the Applications page and type **Windows Firewall**.
2. Right-click **Inbound Rules** and select **New Rule**.
3. In Rule Type, click **Port** and then click **Next**.
4. In Protocol and Ports, select **TCP** and then type **2383** in **Specific local ports**.
5. In Action, click **Allow the connection** and then click **Next**.
6. In Profile, clear any network locations that do not apply and then click **Next**.
7. In Name, type a descriptive name for this rule (for example, **SQL Server Analysis Services (tcp-in) 2383**), and then click **Finish**.
8. To verify that remote connections are enabled, open SQL Server Management Studio or Excel on a different computer and connect to Analysis Services by specifying the network name of the server in **Server name**.

NOTE

Other users will not have access to this server until you grant permissions. For more information, see [Authorizing access to objects and operations \(Analysis Services\)](#).

Netsh AdvFirewall Syntax

- The following command creates an inbound rule that allows incoming requests on TCP port 2383.

```
netsh advfirewall firewall add rule name="SQL Server Analysis Services inbound on TCP 2383" dir=in  
action=allow protocol=TCP localport=2383 profile=domain
```

Configure Windows Firewall access for a named instance of Analysis Services

Named instances of Analysis Services can either listen on a fixed port or on a dynamically assigned port, where SQL Server Browser service provides the connection information that is current for the service at the time of the connection.

SQL Server Browser service listens on TCP port 2382. UDP is not used. TCP is the only transmission protocol used by Analysis Services.

Choose one of the following approaches to enable remote access to a named instance of Analysis Services:

- Use dynamic port assignments and SQL Server Browser service. Unblock the port used by SQL Server Browser service in Windows Firewall. Connect to the server in this format: <servername>\<instancename>.
- Use a fixed port and SQL Server Browser service together. This approach lets you connect using this format: <servername>\<instancename>, identical to the dynamic port assignment approach, except that in this case the server listens on a fixed port. In this scenario, SQL Server Browser Service provides name resolution to the Analysis Services instance listening on the fixed port. To use this approach, configure

the server to listen on a fixed port, unblock access to that port, and unblock access to the port used by SQL Server Browser service.

SQL Server Browser service is only used with named instances, never with the default instance. The service is automatically installed and enabled whenever you install any SQL Server feature as a named instance. If you choose an approach that requires SQL Server Browser service, be sure it remains enabled and started on your server.

If you cannot use SQL Server Browser service, you must assign a fixed port in the connection string, bypassing domain name resolution. Without SQL Server Browser service, all client connections must include the port number on the connection string (for example, AW-SRV01:54321).

Option 1: Use dynamic port assignments and unblock access to SQL Server Browser service

Dynamic port assignments for named instances of Analysis Services are established by the **MSOLAP\$InstanceName** when the service starts. By default, the service claims the first available port number that it finds, using a different port number each time the service is restarted.

Instance name resolution is handled by the SQL Server browser service. Unblocking TCP port 2382 for SQL Server Browser service is always required if you are using dynamic port assignments with a named instance.

NOTE

SQL Server Browser service listens on both UDP port 1434 and TCP port 2382 for the Database Engine and Analysis Services, respectively. Even if you already unblocked UDP port 1434 for the SQL Server Browser service, you must still unblock TCP port 2382 for Analysis Services.

Windows Firewall with Advanced Security

1. On Windows 7 or Windows Vista, in Control Panel, click **System and Security**, select **Windows Firewall**, and then click **Advanced settings**. On Windows Server 2008 or 2008 R2, open Administrator Tools and click **Windows Firewall with Advanced Security**. On Windows Server 2012, open the Applications page and type **Windows Firewall**.
2. To unblock access to SQL Server Browser service, right-click **Inbound Rules** and select **New Rule**.
3. In Rule Type, click **Port** and then click **Next**.
4. In Protocol and Ports, select **TCP** and then type **2382** in **Specific local ports**.
5. In Action, click **Allow the connection** and then click **Next**.
6. In Profile, clear any network locations that do not apply and then click **Next**.
7. In Name, type a descriptive name for this rule (for example, **SQL Server Browser Service (tcp-in) 2382**), and then click **Finish**.
8. To verify that remote connections are enabled, open SQL Server Management Studio or Excel on a different computer and connect to the Analysis Services by specifying the network name of the server and the instance name in this format: <servername>\<instancename>. For example, on a server named **AW-SRV01** with a named instance of **Finance**, the server name is **AW-SRV01\Finance**.

Option 2: Use a fixed port for a named instance

Alternatively, you can assign a fixed port, and then unblock access to that port. This approach offers better auditing capability than if you allowed access to the program executable. For this reason, using a fixed port is the recommended approach for accessing any Analysis Services instance.

To assign a fixed port, follow the instructions in [Use a fixed port for a default or named instance of Analysis](#)

[Services](#) in this topic, then return to this section to unblock the port.

Windows Firewall with Advanced Security

1. On Windows 7 or Windows Vista, in Control Panel, click **System and Security**, select **Windows Firewall**, and then click **Advanced settings**. On Windows Server 2008 or 2008 R2, open Administrator Tools and click **Windows Firewall with Advanced Security**. On Windows Server 2012, open the Applications page and type **Windows Firewall**.
2. To unblock access to Analysis Services, right-click **Inbound Rules** and select **New Rule**.
3. In Rule Type, click **Port** and then click **Next**.
4. In Protocol and Ports, select **TCP** and then type the fixed port in **Specific local ports**.
5. In Action, click **Allow the connection** and then click **Next**.
6. In Profile, clear any network locations that do not apply and then click **Next**.
7. In Name, type a descriptive name for this rule (for example, **SQL Server Analysis Services on port 54321**), and then click **Finish**.
8. To verify that remote connections are enabled, open SQL Server Management Studio or Excel on a different computer and connect to the Analysis Services by specifying the network name of the server and the port number in this format: <servername>:<portnumber>.

Netsh AdvFirewall Syntax

- The following commands create inbound rules that unblock TCP 2382 for SQL Server Browser service and unblock the fixed port that you specified for the Analysis Services instance. You can run either one to allow access to a named Analysis Services instance.

In this sample command, port 54321 is the fixed port. Be sure to replace it with the actual port in use on your system.

```
netsh advfirewall firewall add rule name="SQL Server Analysis Services (tcp-in) on 54321" dir=in  
action=allow protocol=TCP localport=54321 profile=domain
```

```
netsh advfirewall firewall add rule name="SQL Server Browser Services inbound on TCP 2382" dir=in  
action=allow protocol=TCP localport=2382 profile=domain
```

Use a fixed port for a default or named instance of Analysis Services

This section explains how to configure Analysis Services to listen on a fixed port. Using a fixed port is common if you installed Analysis Services as a named instance, but you can also use this approach if business or security requirements specify that you use non-default port assignments.

Note that using a fixed port will alter the connection syntax for the default instance by requiring you to append the port number to the server name. For example, connecting to a local, default Analysis Services instance listening on port 54321 in SQL Server Management Studio would require that you type localhost:54321 as the server name in the Connect to Server dialog box in Management Studio.

If you are using a named instance, you can assign a fixed port with no changes to how you specify the server name (specifically, you can use <servername\instancename> to connect to a named instance listening on a fixed port). This works only if SQL Server Browser service is running and you unblocked the port on which it is listening. SQL Server Browser service will provide redirection to the fixed port based on <servername\instancename>. As long as you open ports for both SQL Server Browser service and the named instance of Analysis Services listening on the fixed port, SQL Server Browser service will resolve the connection

to a named instance.

1. Determine an available TCP/IP port to use.

To view a list of reserved and registered ports that you should avoid using, see [Port Numbers \(IANA\)](#). To view a list of ports that are already in use on your system, open a command prompt window and type **netstat -a -p TCP** to display a list of the TCP ports that are open on the system.

2. After you determine which port to use, specify the port by either editing the **Port** configuration setting in the msmdsrv.ini file or in the General properties page of an Analysis Services instance in SQL Server Management Studio.
3. Restart the service.
4. Configure Windows Firewall to unblock the TCP port you specified. Or, if you are using a fixed port for a named instance, unblock both the TCP port you specified for that instance and TCP port 2382 for SQL Server Browser service.
5. Verify by connecting locally (in Management Studio) and then remotely from a client application on another computer. To use Management Studio, connect to an Analysis Services default instance by specifying a server name in this format: <servername>:<portnumber>. For a named instance, specify the server name as <servername>\<instancename>.

Port configuration for an Analysis Services cluster

An Analysis Services failover cluster always listens on TCP port 2383, regardless of whether you installed it as a default instance or named instance. Dynamic port assignments are not used by Analysis Services when it is installed on a Windows failover cluster. Be sure to open TCP 2383 on every node running Analysis Services in the cluster. For more information about clustering Analysis Services, see [How to Cluster SQL Server Analysis Services](#).

Port configuration for Power Pivot for SharePoint

Server architecture for Power Pivot for SharePoint is fundamentally different depending on which version of SharePoint you are using.

SharePoint 2013

In SharePoint 2013, Excel Services redirects requests for Power Pivot data models, which are subsequently loaded on an Analysis Services instance outside of the SharePoint environment. Connections follow the typical pattern, where an Analysis Services client library on a local computer sends a connection request to a remote Analysis Services instance in the same network.

Because Power Pivot for SharePoint always installs Analysis Services as a named instance, you should assume SQL Server Browser service and dynamic port assignments. As noted earlier, SQL Server Browser service listens on TCP port 2382 for connection requests sent to Analysis Services named instances, redirecting the request to the current port.

Note that Excel Services in SharePoint 2013 does not support the fixed port connection syntax, so make sure SQL Server Browser service is accessible.

SharePoint 2010

If you are using SharePoint 2010, you do not need to open ports in Windows Firewall. SharePoint opens the ports that it requires, and add-ins such as Power Pivot for SharePoint operate within the SharePoint environment. In a Power Pivot for SharePoint 2010 installation, the Power Pivot System Service has exclusive use of the local SQL Server Analysis Services (Power Pivot) service instance that is installed with it on the same computer. It uses local connections, not network connections, to access the local Analysis Services engine.

service that loads, queries, and processes Power Pivot data on the SharePoint server. To request Power Pivot data from client applications, requests are routed through ports that are opened by SharePoint Setup (specifically, inbound rules are defined to allow access to SharePoint - 80, SharePoint Central Administration v4, SharePoint Web Services, and SPUserCodeV4). Because Power Pivot web services run within a SharePoint farm, the SharePoint firewall rules are sufficient for remote access to Power Pivot data in a SharePoint farm.

Configure Service Accounts (Analysis Services)

7/16/2019 • 13 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Product-wide account provisioning is documented in [Configure Windows Service Accounts and Permissions](#), a topic that provides comprehensive service account information for all SQL Server services, including Analysis Services. Refer to it to learn about valid account types, Windows privileges assigned by setup, file system permissions, registry permissions, and more.

This topic provides supplemental information for Analysis Services, including additional permissions necessary for tabular and clustered installations. It also covers permissions needed to support server operations. For example, you can configure processing and query operations to execute under the service account — in which case you will need to grant additional permissions to get this to work.

- [Windows privileges assigned to Analysis Services](#)
- [File System Permissions assigned to Analysis Services](#)
- [Granting additional permissions for specific server operations](#)

An additional configuration step, not documented here, is to register a Service Principal Name (SPN) for the Analysis Services instance and service account. This step enables pass-through authentication from client applications to backend data sources in double-hop scenarios. This step only applies for services configured for Kerberos constrained delegation. See [Configure Analysis Services for Kerberos constrained delegation](#) for further instructions.

Logon account recommendations

In a failover cluster, all instances of Analysis Services should be configured to use a Windows domain user account. Assign the same account to all instances. See [How to Cluster Analysis Services](#) for details.

Standalone instances should use the default virtual account, **NT Service\MSQLServerOLAPService** for the default instance, or **NT Service\MSOLAP\$instance-name** for a named instance. This recommendation applies to Analysis Services instances in all server modes, assuming Windows Server 2008 R2 and later for the operating system, and SQL Server 2012 and later for Analysis Services.

Granting permissions to Analysis Services

This section explains the permissions that Analysis Services requires for local, internal operations, such as starting the executable, reading the configuration file, and loading databases from the data directory. If instead you're looking for guidance on setting permissions for external data access and interoperability with other services and applications, see [Granting additional permissions for specific server operations](#) further on in this topic.

For internal operations, the permission holder in Analysis Services is not the logon account, but a local Windows security group created by Setup that contains the per-service SID. Assigning permissions to the security group is consistent with previous versions of Analysis Services. Also, logon accounts can change over time, but the per-service SID and local security group are constant for the lifetime of the server installation. For Analysis Services, this makes the security group, rather than the logon account, a better choice for holding permissions. Whenever you manually grant rights to the service instance, whether file system permissions or Windows privileges, be sure to grant permissions to the local security group created for the server instance.

The name of the security group follows a pattern. The prefix is always **SQLServerMSASUser\$**, followed by the

computer name, ending with the instance name. The default instance is **MSSQLSERVER**. A named instance is the name given during set up.

You can see this security group in the local security settings:

- Run compmgmt.msc | **Local Users and Groups** | **Groups** | **SQLServerMSASUser\$<server-name>\$MSSQLSERVER** (for a default instance).
- Double-click the security group to view its members.

The sole member of the group is the per-service SID. Right next to it is the logon account. The logon account name is cosmetic, there to provide context to the per-service SID. If you subsequently change the logon account and then return to this page, you'll notice that the security group and per-service SID do not change, but the logon account label is different.

Windows privileges assigned to the Analysis Services service account

Analysis Services needs permissions from the operating system for service startup and to request system resources. Requirements vary by server mode and whether the instance is clustered. If you are unfamiliar with Windows privileges, see [Privileges](#) and [Privilege Constants \(Windows\)](#) for details.

All instances of Analysis Services require the **Log on as a service** (SeServiceLogonRight) privilege. SQL Server Setup assigns the privilege for you on the service account specified during installation. For servers running in Multidimensional and Data Mining mode, this is the only Windows privilege required by the Analysis Services service account for standalone server installations, and it is the only privilege that Setup configures for Analysis Services. For clustered and tabular instances, additional Windows privileges must be added manually.

Failover cluster instances, in either Tabular or Multidimensional mode, must have **Increase scheduling priority** (SeIncreaseBasePriorityPrivilege).

Tabular instances use the following three additional privileges, which must be granted manually after the instance is installed.

| | |
|--|---|
| Increase a process working set
(SeIncreaseWorkingSetPrivilege) | This privilege is available to all users by default through the Users security group. If you lock down a server by removing privileges for this group, Analysis Services might fail to start, logging this error: "A required privilege is not held by the client." When this error occurs, restore the privilege to Analysis Services by granting it to the appropriate Analysis Services security group. |
| Adjust memory quotas for a process
(SeIncreaseQuotaPrivilege) | This privilege is used to request more memory if a process has insufficient resources to complete its execution, subject to the memory thresholds established for the instance. |

Lock pages in memory (SeLockMemoryPrivilege)

This privilege is needed only when paging is turned off entirely. By default, a tabular server instance uses the Windows paging file, but you can prevent it from using Windows paging by setting **VertiPaqPagingPolicy** to 0.

VertiPaqPagingPolicy to 1 (default), instructs the tabular server instance to use the Windows paging file. Allocations are not locked, allowing Windows to page out as needed. Because paging is being used, there is no need to lock pages in memory. Thus, for the default configuration (where **VertiPaqPagingPolicy** = 1), you do not need to grant the **Lock pages in memory** privilege to a tabular instance.

VertiPaqPagingPolicy to 0. If you turn off paging for Analysis Services, allocations are locked, assuming the **Lock pages in memory** privilege is granted to the tabular instance. Given this setting and the **Lock pages in memory** privilege, Windows cannot page out memory allocations made to Analysis Services when the system is under memory pressure. Analysis Services relies on the **Lock pages in memory** permission as the enforcement behind **VertiPaqPagingPolicy** = 0. Note that turning off Windows paging is not recommended. It will increase the rate of out-of-memory errors for operations that might otherwise succeed if paging were allowed. See [Memory Properties](#) for more information about **VertiPaqPagingPolicy**.

To view or add Windows privileges on the service account

1. Run GPEDIT.msc | Local Computer Policy | Computer Configuration | Windows Settings | Security Settings | Local Policies | User Rights Assignments.
2. Review existing policies that include **SQLServerMSASUser\$**. This is a local security group found on computers having an Analysis Services installation. Both Windows privileges and file folder permissions are granted to this security group. Double-click **Log on as a service** policy to see how the security group is specified on your system. The full name of the security group will vary depending on whether you installed Analysis Services as a named instance. Use this security group, rather than the actual service account, when adding account privileges.
3. To add account privileges in GPEDIT, right-click **Increase a process working set** and select **Properties**.
4. Click **Add User or Group**.
5. Enter the user group for the Analysis Services instance. Remember that the service account is a member of a local security group, requiring that you prepend the local computer name as the domain of the account.
The following list shows two examples for a default instance and named instance called "Tabular" on a machine called "SQL01-WIN12", where the machine name is the local domain.
 - SQL01-WIN12\SQL01-WIN12\$SQLServerMSASUser\$MSSQLSERVER
 - SQL01-WIN12\SQL01-WIN12\$SQLServerMSASUser\$TABULAR
6. Repeat for **Adjust memory quotas for a process**, and optionally, for **Lock pages in memory** or **Increase scheduling priority**.

NOTE

Previous versions of Setup inadvertently added the Analysis Services service account to the **Performance Log Users** group. Although this defect has been fixed, existing installations might have this unnecessary group membership. Because the Analysis Services service account does not require membership in the **Performance Log Users** group, you can remove it from the group.

File System Permissions assigned to the Analysis Services service account

NOTE

See [Configure Windows Service Accounts and Permissions](#) for a list of permissions associated with each program folder.

See [Configure HTTP Access to Analysis Services on Internet Information Services \(IIS\) 8.0](#) for file permission information related to IIS configuration and Analysis Services.

All file system permissions required for server operations—including permissions needed for loading and unloading databases from a designated data folder—are assigned by SQL Server Setup during installation.

The permission holder on data files, program file executables, configuration files, log files, and temporary files is a local security group created by SQL Server Setup.

There is one security group created for each instance that you install. The security group is named after the instance—either **SQLServerMSASUser\$MSSQLSERVER** for the default instance, or **SQLServerMSASUser\$<servername>\$<instancename>** for a named instance. Setup provisions this security group with the file permissions required to perform server operations. If you check the security permissions on the `\MSAS13.MSSQLSERVER\OLAP\BIN` directory, you will see that the security group (not the service account or its per-service SID) is the permission holder on that directory.

The security group contains one member only: the per-service Security Identifier (SID) of the Analysis Services instance startup account. Setup adds the per-service SID to the local security group. The use of a local security group, with its SID membership, is a small but noticeable difference in how SQL Server Setup provisions Analysis Services, as compared to the Database Engine.

If you believe that file permissions are corrupted, follow these steps to verify the service is still correctly provisioned:

1. Use the Service Control command line tool (`sc.exe`) to obtain the SID of a default service instance.

```
SC showsid MSSqlServerOlapService
```

For a named instance (where the instance name is Tabular), use this syntax:

```
SC showsid MS0lap$Tabular
```

2. Use **Computer Manager | Local Users and Groups | Groups** to inspect the membership of the `SQLServerMSASUser$<servername>$<instancename>` security group.

The member SID should match the per-service SID from step 1.

3. Use **Windows Explorer | Program Files | Microsoft SQL Server | MSASxx.MSSQLServer | OLAP | bin** to verify folder Security properties are granted to the security group in step 2.

NOTE

Never remove or modify a SID. To restore a per-service SID that was inadvertently deleted, see <https://support.microsoft.com/kb/2620201>.

More about per-service SIDs

Every Windows account has an associated [SID](#), but services can also have SIDs, hence referred to as per-service SIDs. A per-service SID is created when the service instance is installed, as a unique, permanent fixture of the service. The per-service SID is a local, machine-level SID generated from the service name. On a default instance, its user friendly name is NT SERVICE\MSSQLServerOLAPService.

The benefit of a per-service SID is that it allows the more widely-visible logon account to be changed arbitrarily, without affecting file permissions. For example, suppose you installed two instances of Analysis Services, a default instance and named instance, both running under the same Windows user account. While the logon account is shared, each service instance will have a unique per-service SID. This SID is distinct from the SID of the logon account. The per-service SID is used for file permissions and Windows privileges. In contrast, the logon account SID is used for authentication and authorization scenarios — different SIDS, used for different purposes.

Because the SID is immutable, file system ACLs created during service installation can be used indefinitely, regardless of how often you change the service account. As an added security measure, ACLs that specify permissions via a SID ensure that program executables and data folders are accessed only by a single instance of a service, even if other services run under the same account.

Granting additional Analysis Services permissions for specific server operations

Analysis Services executes some tasks in the security context of the service account (or logon account) that is used to start Analysis Services, and executes other tasks in the security context of the user who is requesting the task.

The following table describes additional permissions required to support tasks executing as the service account.

| SERVER OPERATION | WORK ITEM | JUSTIFICATION |
|---|---|---|
| Remote access to external relational data sources | Create a database login for the service account | Processing refers to data retrieval from an external data source (usually a relational database), which is subsequently loaded into an Analysis Services database. One of the credential options for retrieving external data is to use the service account. This credential option works only if you create a database login for the service account and grant read permissions on the source database. See Set Impersonation Options (SSAS - Multidimensional) for more information about how the service account option is used for this task. Similarly, if ROLAP is used as the storage mode, the same impersonation options are available. In this case, the account must also have write access to the source data to process the ROLAP partitions (that is, to store aggregations). |

| SERVER OPERATION | WORK ITEM | JUSTIFICATION |
|---------------------------------------|--|--|
| DirectQuery | Create a database login for the service account | <p>DirectQuery is a tabular feature used to query external datasets that are either too large to fit inside the tabular model or have other characteristics that make DirectQuery a better fit than the default in-memory storage option. One of the connection options available in DirectQuery mode is to use the service account. Once again, this option works only when the service account has a database login and read permissions on the target data source. See Set Impersonation Options (SSAS - Multidimensional) for more information about how the service account option is used for this task. Alternatively, the credentials of the current user can be used to retrieve data. In most cases this option entails a double-hop connection, so be sure to configure the service account for Kerberos constrained delegation so that the service account can delegate identities to a downstream server. For more information, see Configure Analysis Services for Kerberos constrained delegation.</p> |
| Remote access to other SSAS instances | Add the service account to Analysis Services database roles defined on the remote server | <p>Remote partitions and referencing linked objects on other remote Analysis Services instances are both system capabilities requiring permissions on a remote computer or device. When a person creates and populates remote partitions, or sets up a linked object, that operation runs in the security context of the current user. If you subsequently automate these operations, Analysis Services will access remote instances in the security context of its service account. In order to access linked objects on a remote instance of Analysis Services, the logon account must have permission to read the appropriate objects on the remote instance, such as Read access to certain dimensions. Similarly, using remote partitions requires that the service account have administrative rights on the remote instance. Such permissions are granted on the remote Analysis Services instance, using roles that associate permitted operations with a specific object. See Grant database permissions (Analysis Services) for instructions on how to grant Full Control permissions that allow processing and query operations. See Create and Manage a Remote Partition (Analysis Services) for more information about remote partitions.</p> |

| SERVER OPERATION | WORK ITEM | JUSTIFICATION |
|--|---|---|
| Writeback | Add the service account to Analysis Services database roles defined on the remote server | When enabled in client applications, writeback is a feature of multidimensional models that allows the creation of new data values during data analysis. If writeback is enabled within any dimension or cube, the Analysis Services service account must have write permissions to the writeback table in the source SQL Server relational database. If this table does not already exist and needs to be created, the Analysis Services service account must also have create table permissions within the designated SQL Server database. |
| Write to a query log table in a SQL Server relational database | Create a database login for the service account and assign write permissions on the query log table | You can enable query logging to collect usage data in a database table for subsequent analysis. The Analysis Services service account must have write permissions to the query log table in the designated SQL Server database. If this table does not already exist and needs to be created, the Analysis Services logon account must also have create table permissions within the designated SQL Server database. For more information, see Improve SQL Server Analysis Services Performance with the Usage Based Optimization Wizard (Blog) and Query Logging in Analysis Services (Blog) . |

Grant server admin rights to an Analysis Services instance

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Members of the Server administrator role within an instance of Analysis Services have unrestricted access to all Analysis Services objects and data in that instance. A user must be a member of the Server administrator role to perform any server-wide task, such as creating or processing a database, modifying server properties, or launching a trace (other than for processing events).

Role membership is established when Analysis Services is installed. The user running the Setup program can add him or herself to the role, or add another user. You must specify at least one administrator before Setup will allow you to continue.

By default, members of the local Administrators group are also granted administrative rights in Analysis Server. Although the local group is not explicitly granted membership in the Analysis Services server administrator role, local administrators can create databases, add users and permissions, and perform any other task allowed to system administrators. The implicit granting of administrator permissions is configurable. It is determined by the **BuiltinAdminsAreServerAdmins** server property, which is set to **true** by default. You can change this property in SQL Server Management Studio. For more information, see [Security Properties](#).

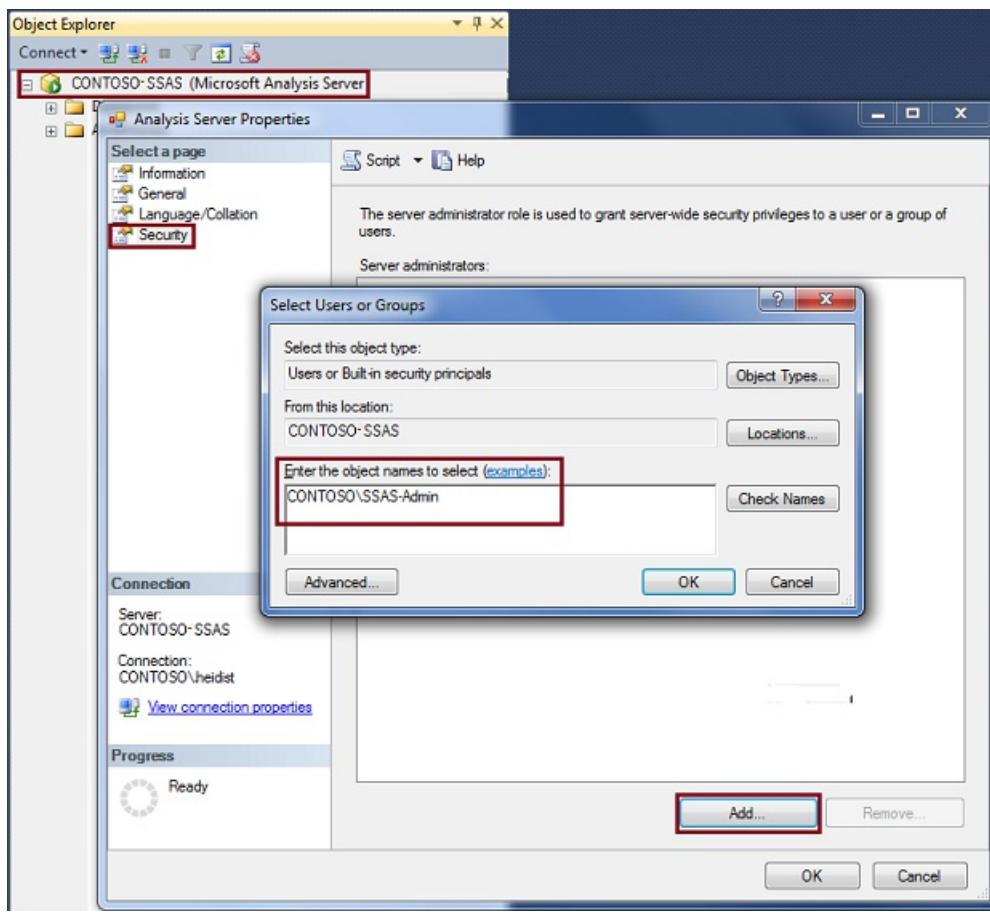

Post-installation, you can modify role membership to add any additional users who require full rights to the service. You can also manage server roles by using Analysis Management Objects (AMO). For more information, see [Developing with Analysis Management Objects \(AMO\)](#).

NOTE

Analysis Services provides a progression of increasingly granular roles for processing and querying at server, database, and object levels. See [Roles and Permissions \(Analysis Services\)](#) for instructions on how to use these roles.

Modify Server Role Membership

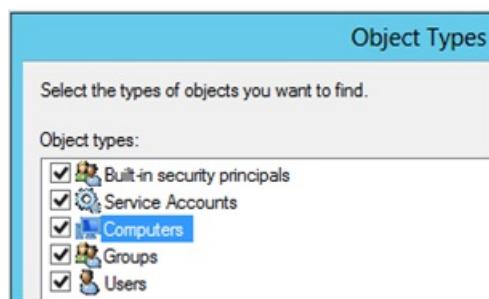

1. In SQL Server Management Studio, connect to the instance of Analysis Services, and then right-click the instance name in Object Explorer and then click **Properties**.
2. Click **Security** in the **Select a Page** pane, and then click **Add** at the bottom of the page to add one or more Windows users or groups to the server role.

Add computer accounts

You can also use SQL Server Management Studio to make a computer account a member of the Analysis Services administrators group.

1. In the **Select Users or Groups** dialog, click **Locations**.
2. Select the domain the computers that you want to add are a member of or select **Entire directory** and click **Ok**.
3. Click **Object Types**.
4. Select **Computers** and click **Ok**.

5. In the **Enter the object names to select** text box, type the name of the computer and click **Check Names** to verify the computer account is found in the current Locations. If the computer account is not found, verify the computer name and the correct domain the computer is a member of.

NT Service\SSASTelemetry account

NT Service/SSASTelemetry is a low-privileged machine account created during setup and used exclusively to run the Analysis Services implementation of the Customer Experience Improvement Program (CEIP) service. This service requires admin rights on the Analysis Services instance to run several discover commands. See [Customer Experience Improvement Program for SQL Server Data Tools](#) and [Microsoft SQL Server Privacy](#)

[Statement](#) for more information.

Features off by default (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

An instance of Analysis Services is designed to be secure by default. Therefore, features that might compromise security are disabled by default. The following features are installed in a disabled state and must specifically be enabled if you want to use them.

Feature List

To enable the following features, connect to Analysis Services using SQL Server Management Studio. Right-click the instance name and choose **Facets**. Alternatively, you can enable these features through server properties, as described in the next section.

- Ad Hoc Data Mining (OpenRowset) Queries
- Linked Objects (To)
- Linked Objects (From)
- Listen Only On Local Connections
- User Defined Functions

Server properties

Additional features that are off by default can be enabled through server properties. Connect to Analysis Services using SQL Server Management Studio. Right-click the instance name and choose **Properties**. Click **General**, and then click **Show Advanced** to display a larger property list.

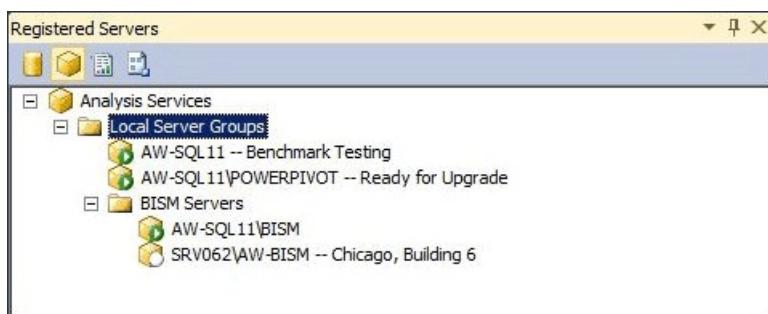

- Ad Hoc Data Mining (OpenRowset) Queries
- Allow Session Mining Models (Data Mining)
- Linked Objects (To)
- Linked Objects (From)
- COM based user-defined functions
- Flight Recorder Trace Definitions (templates).
- Query logging
- Listen Only On Local Connections
- Binary XML
- Compression
- Group affinity. See [Thread Pool Properties](#) for details.

Register an Analysis Services Instance in a Server Group

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

If you have a large number of Analysis Services server instances, you can create server groups in Management Studio to make server administration easier. The purpose of a server group is to provide proximity among a group of related servers within the administrative workspace. For example, suppose you are tasked with managing ten separate instances of Analysis Services. Grouping them by server mode, up-time criteria, or by department or region would allow you to view and connect to instances that share the same characteristics more easily. You can also add descriptive information that helps you remember how the server is used.

Server groups can be created in a hierarchical structure. Local Server Group is the root node. It always contains instances of Analysis Services that run on the local computer. You can add remote servers to any group, including the local group.

After you create a server group, you must use the Registered Servers pane to view and connect to the member servers. The pane filters SQL Server instances by server type (Database Engine, Analysis Services, Reporting Services, and Integration Services). You click a server type to view the server groups created for it. To connect to a specific server within group, you double-click a server in the group.

The connection information that is defined for the server, including the server name, is persisted with server registration. You cannot modify the connection information, or use the registered name when connecting to the server using other tools.

Create a Server Group and Add Registered Servers

1. In Management Studio, click Registered Servers on the View menu to open the Registered Servers pane in the workspace. By default, a local Server Group is already created. All instances of Analysis Services that are running on the local server are members.
2. Right-click Local Server Group, select New Server Group, and give the group a name.
3. Right-click the server group and select New Server Registration. Enter the network name of a local or remote server, including the instance name if the server was installed as a named instance. Optionally, you can provide a registered server name that appears in Registered Servers. This name is used in Registered Servers only. You cannot use it to rename a server, nor can you use it in a connection string. A registered server name can be more descriptive than the actual server name or include other identifying characteristics that help you distinguish this server from other servers.

Determine the Server Mode of an Analysis Services Instance

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

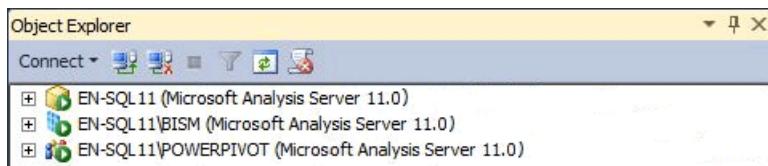

Analysis Services can be installed in one of three server modes: Multidimensional and Data Mining (default), Power Pivot for SharePoint, and Tabular. The server mode of an Analysis Services instance is determined during setup when you choose options for installing the server.

The server mode determines the type of solution that you create and deploy. If you did not install the server software and you want to know in which mode the server was installed, you can use the information in this topic to determine the mode. For more information about feature availability in a specific mode, see [Comparing Tabular and Multidimensional Solutions](#).

If you do not want to use the server mode that you installed, you must uninstall and then reinstall the software, choosing the mode that you prefer. Alternatively, you can install an additional instance of Analysis Services on the same computer so that you have multiple instances running different modes.

Server Icons in Object Explorer

The easiest way to determine server mode is to connect to the server in SQL Server Management Studio and note the icon next to the server name in Object Explorer. The following illustration shows three instances of Analysis Services deployed in Multidimensional, Tabular, and Power Pivot modes:

Viewing DeploymentMode Property in MSMDsrv.ini File

Alternatively, you can check the **DeploymentMode** property in the msmdsrv.ini file that is included in every Analysis Services instance. The value of this property identifies the server mode. Valid values are 0 (Multidimensional), 1 (SharePoint), or 2 (Tabular). You must be an Analysis Services administrator (that is, a member of the Server role) to open the msmdsrv.ini file. This file contains structured XML. You can use Notepad or another text editor to view the file.

Caution

Do not change the value of the **DeploymentMode** property. Changing the property manually after the server is installed is not supported.

About the DeploymentMode Property

DeploymentMode property determines the operational context of an Analysis Services server instance. This property is referred to as 'server mode' in dialog boxes, messages, and documentation. This property is initialized by Setup based on how you install Analysis Services. This property should be considered internal only, always using the value specified by Setup.

Valid values for this property include the following:

| VALUE | DESCRIPTION |
|-------|---|
| 0 | This is the default value. It specifies multidimensional mode, used to service multidimensional databases that use MOLAP, HOLAP, and ROLAP storage, as well as data mining models. |
| 1 | Specifies Analysis Services instances that were installed as part of a Power Pivot for SharePoint deployment. Do not change the deployment mode property of Analysis Services instance that is part of a Power Pivot for SharePoint installation. Power Pivot data will no longer run on the server if you change the mode. |
| 2 | Specifies Tabular mode used for hosting tabular model databases that use in-memory storage or DirectQuery storage. |

Each mode is exclusive of the other. A server that is configured for tabular mode cannot run Analysis Services databases that contain cubes and dimensions. If the underlying computer hardware can support it, you can install multiple instances of Analysis Services on the same computer and configure each instance to use a different deployment mode. Remember that Analysis Services is a resource intensive application. Deploying multiple instances on the same system is recommended only for high-end servers.

Rename an Analysis Services Instance

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can rename an existing instance of Microsoft Analysis Services by using the **Rename Instance** tool, installed with Management Studio (Web install).

IMPORTANT

While renaming the instance, the Analysis Services Instance Rename tool runs under elevated privileges, updating the Windows service name, security accounts, and registry entries associated with that instance. To ensure that these actions are performed, be sure to run this tool as a local system administrator.

The Analysis Services Instance Rename tool does not modify the program folder that was created for the original instance. Do not modify the program folder name to match the instance you are renaming. Changing a program folder name can prevent Setup from repairing or uninstalling the installation.

NOTE

The Analysis Services Instance Rename tool is not supported for use in a cluster environment.

To rename an instance of Analysis Services

1. Launch the **Instance Rename** tool, **asinstancerename.exe**, from C:\Program Files (x86)\Microsoft SQL Server\130\Tools\Binn\ManagementStudio.
2. In the **Rename Instance** dialog box, in the **Instance to rename** list, select the instance that you want to rename.
3. In the **New instance name** box, enter the new name for the instance.
4. Verify that the user name and password are correct, and then click **Rename**.

The Analysis Services instance will be stopped and restarted as part of the name change.

Post-rename checklist

1. To resume access to databases that are running on the renamed instance, you will need to manually update the data connections in Excel or other client applications. Also check any predefined connections, such as Reporting Services shared data sources, Excel ODC files, or BI Semantic Model connection files that might reference the instance you just renamed. For more information, see [Connect to Analysis Services](#).
2. Update PowerShell scripts or AMO scripts that you routinely use to backup, synchronize, or process databases.
3. Update project properties for Analysis Services projects that you work with in Visual Studio with Analysis Services projects. For tabular mode server instances, be sure to update the Workspace Server property on the model.bim file, as well as the Server property on the project.
4. Depending on how you specified the service account, you might need to update database logins or file permissions that grant data access rights to the service (for example, if you use the service account to process data or access linked objects on another server).

Updating a database login or file permissions will be necessary if you used a virtual account to provision the service. Virtual accounts are based on the instance name, so if you rename the instance, the virtual account is also updated at the same time. This means that any previous logins or permissions that you created for the previous instance are no longer valid.

The following example provides an illustration. Suppose you installed a tabular mode server as an instance named "Tabular" using the default virtual account, resulting in the following configuration:

- a. Instance name = <server>\TABULAR
- b. Service name = MSOLAP\$TABULAR
- c. Virtual account = NT Service\ MSOLAP\$TABULAR

Now suppose you rename the instance to "TAB2". As a result of the name change, your configuration would now look like the following:

- a. Instance name = <server>\TAB2
- b. Service name = MSOLAP\$TAB2
- c. Virtual account = NT Service\ MSOLAP\$TAB2

As you can see, database and file permissions that were previously granted to "NT Service\ MSOLAP\$TABULAR" are no longer valid. To ensure that tasks and operations performed by the service run as before, you would now need to grant new database and file permissions to "NT Service\ MSOLAP\$TAB2".

Tabular modeling overview

10/25/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Tabular models in Analysis Services are databases that run in-memory or in DirectQuery mode, connecting to data directly from back-end relational data sources. By using state-of-the-art compression algorithms and multi-threaded query processor, the Analysis Services Vertipaq analytics engine delivers fast access to tabular model objects and data by reporting client applications like Power BI and Excel.

While in-memory models are the default, DirectQuery is an alternative query mode for models that are either too large to fit in memory, or when data volatility precludes a reasonable processing strategy. DirectQuery achieves parity with in-memory models through support for a wide array of data sources, ability to handle calculated tables and columns in a DirectQuery model, row level security via DAX expressions that reach the back-end database, and query optimizations that result in faster throughput.

Tabular models are created in Visual Studio with Analysis Services projects using the Tabular model project template. The project template provides a design surface for creating semantic model objects like tables, partitions, relationships, hierarchies, measures, and KPIs.

Tabular models can be deployed to Azure Analysis Services or an instance of SQL Server Analysis Services configured for Tabular server mode. Deployed tabular models can be managed in SQL Server Management Studio.

Compatibility level for tabular models

11/8/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The *compatibility level* refers to release-specific behaviors in the Analysis Services engine. For example, DirectQuery and tabular object metadata have different implementations depending on the compatibility level. In-general, you should choose the latest compatibility level supported by your servers.

The latest supported compatibility level is 1500

Major features in the 1500 compatibility level include:

- [Calculation groups](#)
- [Many-to-many relationships](#)

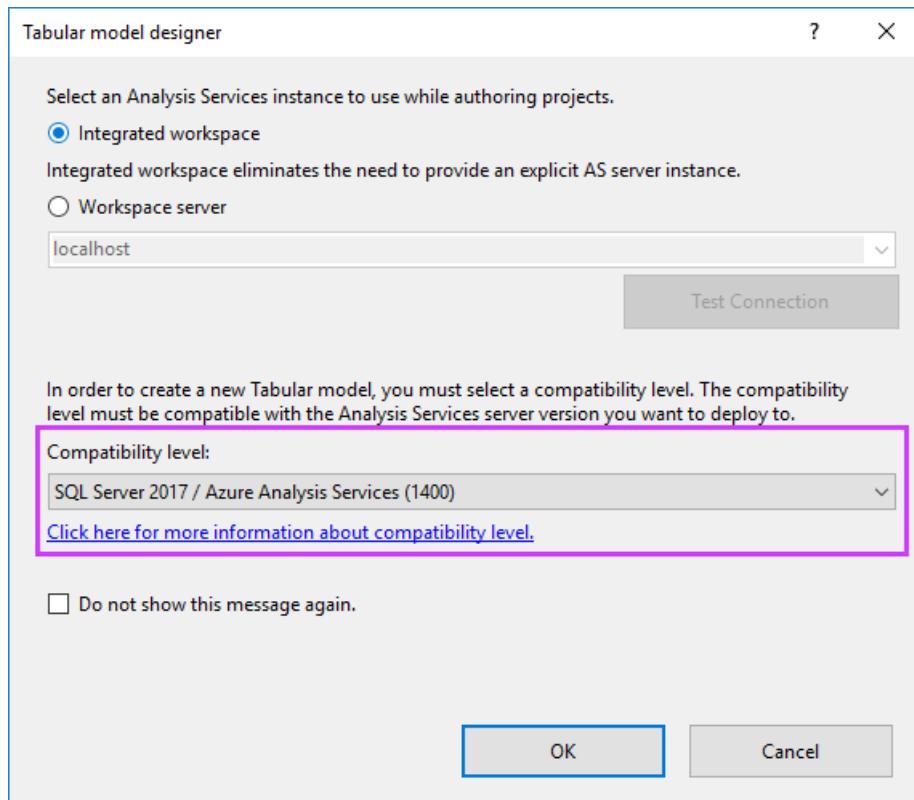

Supported compatibility levels by version

| Compatibility level | Server version |
|---------------------|--|
| 1500 | Azure Analysis Services, SQL Server 2019 |
| 1400 | Azure Analysis Services, SQL Server 2019, SQL Server 2017 |
| 1200 | Azure Analysis Services, SQL Server 2019, SQL Server 2017, SQL Server 2016 |
| 1103 | SQL Server 2017*, SQL Server 2016, SQL Server 2014, SQL Server 2012 SP1 |
| 1100 | SQL Server 2017*, SQL Server 2016, SQL Server 2014, SQL Server 2012 SP1, SQL Server 2012 |

* 1100 and 1103 compatibility levels are deprecated in SQL Server 2017.

Set compatibility level

When creating a new tabular model project in Visual Studio, you can specify the compatibility level on the **Tabular model designer** dialog.

If you select the **Do not show this message again** option, all subsequent projects will use the compatibility level you specified as the default. You can change the default compatibility level in SSDT in **Tools > Options**.

To upgrade a tabular model project in SSDT, set the **Compatibility Level** property in the model **Properties** window. Keep in-mind, upgrading the compatibility level is irreversible.

Check compatibility level for a tabular database in SSMS

In SSMS, right-click the database name > **Properties** > **Compatibility Level**.

Check supported compatibility level for a server in SSMS

In SSMS, right-click the server name > **Properties** > **Supported Compatibility Level**.

This property specifies the highest compatibility level of a database that will run on the server. The supported compatibility level is read-only cannot be changed.

NOTE

In SSMS, when connected to a SQL Server Analysis Services server, Azure Analysis Services server, or Power BI Premium workspace, the Supported Compatibility Level property will show 1200. This is a known issue and will be resolved in an upcoming SSMS update. When resolved, this property will show the highest supported compatibility level.

[Create a new tabular model project](#)

Tabular model designer

10/22/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The tabular model designer is part of Analysis Services projects extension for Microsoft Visual Studio, with additional project type templates specifically for developing professional tabular model solutions. To learn more, see [Tools](#).

Benefits

When you install Analysis Services projects extension for Visual Studio, new project templates for creating tabular models are added to the available project types. After creating a new tabular model project by using one of the templates, you can begin model authoring by using the tabular model designer tools and wizards.

In addition to new templates and tools for authoring professional multidimensional and tabular model solutions, the Visual Studio environment provides debugging and project lifecycle capabilities that ensure you create most BI solutions for your organization. For more information about Visual Studio, see [Getting Started with Visual Studio](#).

Project templates

When you install Visual Studio with Analysis Services projects, the following tabular model project templates are added to the project types:

Analysis Services Tabular Project

This template can be used to create a new, blank tabular model project. Compatibility levels are specified when you create the project.

Import from Server (Tabular)

This template can be used to create a new tabular model project by extracting the metadata from an existing tabular model in Analysis Services.

Older models have older compatibility levels. You can upgrade by changing the Compatibility Level property after importing the model definition.

Import from Power Pivot

This template is used for creating a new tabular model project by extracting the metadata and data from a Power Pivot for Excel file.

Windows and menus

The Visual Studio with Analysis Services projects tabular model authoring environment includes the following:

Designer window

The designer window is used to author tabular models by providing a visual representation of the model. When you open the Model.bim file, the model opens in the designer window. You can author a model in the designer window by using two different view modes:

Data view

The data view displays tables in a tabular, grid format. You can also define measures by using the measure grid, which can be shown for each table in Data View only.

Diagram view

The diagram view displays tables, with relationships between them, in a graphical format. Columns, measures, hierarchies, and KPIs can be filtered, and you can choose to view the model by using a defined perspective.

Most model authoring tasks can be performed in either view.

View Code window

You can view the code behind a Model.bim file when you right-click select **View Code** on the file in Solution Explorer. For Tabular models at compatibility level 1200 and later, the model definition is expressed in JSON.

Note that you will need a full version of Visual Studio that provides the JSON editor. You can download and install the [free Visual Studio Community edition](#) if you do not require the additional features in commercial editions.

Solution Explorer

The Solution Explorer window presents the active solution as a logical container for a tabular model project and its associated items. The model project (.lsmproj) contains only a References object (empty) and the Model.bim file. You can open project items for modification and perform other management tasks directly from this view.

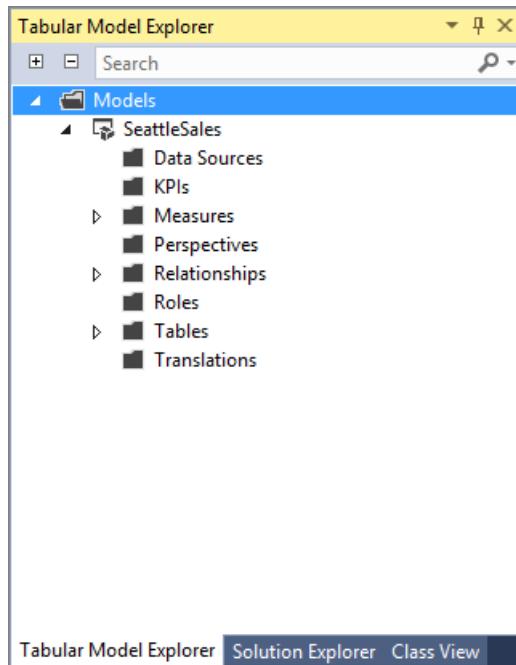

Tabular model solutions typically contain only one project; however, a solution can contain other projects too, for example, Integration Services or Reporting services project. You can add any number of files provided they are not of the same type as tabular model project files and their Build Action property is set to None, or Copy to Output property is set to Do Not Copy.

To view Solution Explorer, click the **View** menu, and then click **Solution Explorer**.

Tabular Model Explorer

Tabular Model Explorer helps you navigate metadata objects in tabular models.

To show Tabular Model Explorer, click **View > Other Windows**, and then click **Tabular Model Explorer**.

Tabular Model Explorer organizes metadata objects into a tree structure that closely resembles the schema of a tabular model. Data Sources, Perspectives, Relationships, Roles, Tables, and Translations correspond to top-level schema objects. There are some exceptions, specifically KPIs and Measures, which technically aren't top-level objects, but child objects of the various tables in the model. However, having consolidated top-level containers for all KPIs and Measures makes it easier to work with these objects, especially if your model includes a very large number of tables. Measures are also listed under their corresponding parent tables, so you have a clear view of the actual parent-child relationships. If you select a measure in the top-level Measures container, the same measure is also selected in the child collection under its table, and vice-versa.

Object nodes in Tabular Model Explorer are linked to appropriate menu options that until now were hiding under the Model, Table, and Column menus in Visual Studio. You can right-click an object to explore options for the object type. Not all object node types have a context menu yet, but additional options and improvements are coming in subsequent releases.

Tabular Model Explorer also offers a convenient search feature. Just type in a portion of the name in the Search box and Tabular Model Explorer narrows down the tree view to the matches.

Properties window

The Properties window lists the properties of the selected object. The following objects have properties that can be viewed and edited in the Properties window:

- Model.bim
- Table
- Column
- Measure

Project properties display only the project name and project folder in the Properties window. Projects also have additional deployment Options and deployment server settings that you can set using a modal properties dialog box. To view these properties, in **Solution Explorer**, right click the project, and then click **Properties**.

Fields in the Properties window have embedded controls that open when you click them. The type of edit control depends on the particular property. Controls include edit boxes, dropdown lists, and links to custom dialog boxes. Properties that are shown as dimmed are read-only.

To view the **Properties** window, click the **View** menu, and then click **Properties Window**.

Error List

The Error List window contains messages about the model state:

- Notifications about security best practices.
- Requirements for data processing.
- Semantic error information for calculated columns, measures, and row filters for roles. For calculated columns, you can double-click the error message to navigate to the source of the error.
- DirectQuery validation errors.

By default, the **Error List** does not appear unless an error is returned. You can, however, view the **Error List** window at any time. To view the **Error List** window, click the **View** menu, and then click **Error List**.

Output

Build and deployment information is displayed in the **Output** Window (in addition to the modal progress dialog). To view the **Output** window, click the **View** menu, and then click **Output**.

Menu items

When you install Visual Studio with Analysis Services projects, additional menu items specifically for authoring tabular models are added to the Visual Studio menu bar. The **Model** menu can be used to launch the Data Import Wizard, view existing connections, process workspace data, and browse the model workspace in Microsoft Excel. The **Table** menu is used to create and manage relationships between tables, create and manage measures, specify data table settings, specify calculation options, and specify other table properties. With the **Column** menu, you can add and delete columns in a table, hide and unhide columns, and specify other column properties such as data types and filters. You can build and deploy tabular model solutions on the **Build** menu. Copy/Paste functions are included on the **Edit** menu.

In addition to these menu items, additional settings are added to the Analysis Services options on the Tools menu items.

Toolbar

The Analysis Services toolbar provides quick and easy access to the most frequently used model authoring commands.

[Tabular model projects](#)

Workspace database

10/22/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The tabular model workspace database, used during model authoring, is created when you create a new tabular model project in Visual Studio with Analysis Services projects.

Specifying a workspace instance

When you create a new tabular model project in Visual Studio with Analysis Services projects, you can specify an Analysis Services server instance to use while authoring your project:

Integrated workspace - Recommended. Utilizes Visual Studio's own internal instance. Use this setting when creating a project that will be deployed to Azure Analysis Services.

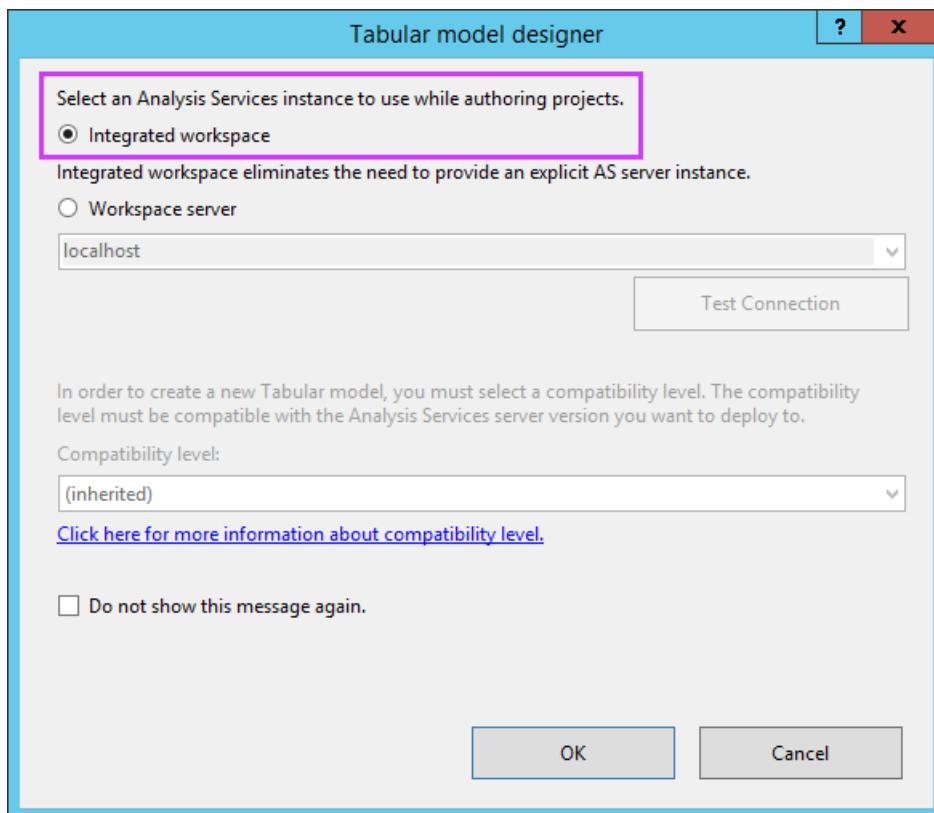

Workspace server - A workspace database is created on an explicit instance, often on the same computer as Visual Studio or another computer in the same network. While you can specify an Azure Analysis Services server, it's not recommended.

Integrated workspace

With Integrated workspace, a working database is created in-memory using Visual Studio's own implicit instance. Integrated workspace mode significantly reduces the complexity of authoring tabular projects in Visual Studio because a separate explicit server is not required.

By using Integrated workspace mode, Visual Studio dynamically starts its own internal instance in the background and loads the database. You can add and view tables, columns, and data in the model designer. If you add additional tables, columns, relationships, etc., you're modifying the workspace database. Integrated workspace mode does not change how Visual Studio works with a workspace server and database. What changes is where Visual Studio hosts the workspace database.

You can select Integrated workspace mode when creating a new tabular model project in Visual Studio.

By using the Workspace Database and Workspace Server properties for model.bim, you can discover the name of the temporary database and the TCP port of the internal SSAS instance where Visual Studio hosts the database. You can connect to the workspace database with SSMS as long as Visual Studio has the database loaded. The Workspace Retention setting specifies that Visual Studio keeps the workspace database on disk, but no longer in memory after a model project is closed. This ensures less memory is consumed than if the model was kept in memory at all times. If you want to control these settings, set the Integrated Workspace Mode property to False and then provide an explicit workspace server. An explicit workspace server also make sense if the data you are importing into a model exceeds the memory capacity of your Visual Studio workstation.

NOTE

When using Integrated workspace mode, the local Analysis Services instance is 64-bit, while Visual Studio runs in the 32-bit environment of Visual Studio. If you're connecting to special data sources, make sure you install both the 32-bit and 64-bit versions of the corresponding data providers on your workstation. The 64-bit provider is required for the 64-bit Analysis Services instance and the 32-bit version is required for the Table Import Wizard in Visual Studio.

Workspace server

A workspace database is created on the instance, specified in the Workspace Server property, when you create a new project by using one of the tabular model project templates in Visual Studio. Each tabular model project will have its own workspace database. You can use SQL Server Management Studio to view the workspace database on the server. The workspace database name includes the project name, followed by an underscore, followed by the username, followed by an underscore, followed by a GUID.

The workspace database resides in-memory while the tabular model project is open in Visual Studio. When you close the project, the workspace database is either kept in-memory, stored to disk and removed from memory (default), or removed from memory and not stored on disk, as determined by the Workspace Retention property. For more information about the Workspace Retention property, see [Workspace Database Properties](#) later in this topic.

After you've added data to your model project by using the Table Import Wizard or by using copy/paste, when you view the tables, columns, and data in the model designer, you are viewing the workspace database. If you add additional tables, columns, relationships, etc. you are changing the workspace database.

When you deploy a tabular model project, the deployed model database, which is essentially a copy of the workspace database, is created on the Analysis Services server instance specified in the Deployment Server property. For more information about the Deployment Server property, see [Project properties](#).

The model workspace database typically resides on localhost or a local named instance of an Analysis Services server. You can use a remote instance to host the workspace database, however, this configuration is not recommended due to latency during data queries and other restrictions. Optimally, the instance of that will host the workspace databases is on the same computer as Visual Studio. Authoring model projects on the same computer as the instance that hosts the workspace database can improve performance.

Remote workspace databases have the following restrictions:

- Potential latency during queries.
- The Data Backup property cannot be set to **Backup to disk**.
- You cannot import data from a Power Pivot workbook when creating a new tabular model project by using the Import from Power Pivot project template.

IMPORTANT

The model's compatibility level and the Workspace Server must correspond.

NOTE

If any of the tables in your model will contain a large number of rows, consider importing only a subset of the data during model authoring. By importing a subset of the data, you can reduce processing time and consumption of workspace database server resources.

NOTE

The preview window in the Select Tables and Views page in the Table Import Wizard, Edit Table Properties dialog box, and Partition Manager dialog box show tables, columns, and rows at the data source, and may not show the same tables, columns, and rows as the workspace database.

Workspace Database Properties

Workspace database properties are included in the model properties. To view model properties, in Visual Studio, in **Solution Explorer**, click the **Model.bim** file. Model properties can be configured using the **Properties** window. Workspace database specific properties include:

NOTE

Integrated Workspace Mode, **Workspace Server**, **Workspace Retention**, and **Data Backup** properties have default settings applied when you create a new model project. You can change the default settings for new model projects on the **Data Modeling** page in **Analysis Server** settings in the Tools\Options dialog box. These properties, as well as others, can also be set for each model project in the **Properties** window. Changing default settings will not apply to model projects already created. For more information, see [Configure default data modeling and deployment properties](#).

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------|-----------------|-------------|
|----------|-----------------|-------------|

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------------------------------|-----------------|--|
| Integrated Workspace Mode | True, False | If Integrated workspace mode is selected for the workspace database when the project is created, this property will be True. If Workspace server mode is selected when the project is created, this property will be False. |
| Workspace database | Name | The name of the workspace database. This property cannot be edited when Integrated Workspace Mode is True . |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------------------------|--------------------|---|
| Workspace Retention | Unload from memory | <p>Specifies how a workspace database is retained after a model project is closed. A workspace database includes model metadata and imported data. In some cases, the workspace database can be very large and consume a large amount of memory. By default, when you close a model project in Visual Studio, the workspace database is unloaded from memory. When changing this setting it is important to consider your available memory resources as well as how often you plan to work on the model project. This property setting has the following options:</p> <p>Keep in memory - Specifies to keep the workspace database in memory after a model project is closed. This option will consume more memory; however, when opening a model project in Visual Studio, fewer resources are consumed and the workspace database will load faster.</p> <p>Unload from memory - Specifies to keep the workspace database on disk, but no longer in memory after a model project is closed. This option will consume less memory; however, when opening a model project in Visual Studio, the workspace database must be re-attached; additional resources are consumed and the model project will load more slowly than if the workspace database is kept in memory. Use this option when in-memory resources are limited or when working on a remote workspace database.</p> <p>Delete workspace - Specifies to delete the workspace database from memory and not keep the workspace database on disk after the model project is closed. This option will consume less memory and storage space; however, when opening a model project in Visual Studio, additional resources are consumed and the model project will load more slowly than if the workspace database is kept in memory or on-disk. Use this option when only occasionally working on model projects.</p> <p>The default setting for this property can be changed on the Data Modeling page in Analysis Server settings in the Tools\Options dialog box. This property cannot be edited when Integrated Workspace Mode is True.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------------|-----------------|--|
| Workspace Server | localhost | <p>This property specifies the default server that will be used to host the workspace database while the model project is being authored in Visual Studio. All available instances running on the local computer are included in the listbox.</p> <p>To specify a different server (running in Tabular mode), type the server name. The user logged on must be an Administrator on the server.</p> <p>Note that It is recommended you specify a local server as the workspace server. For workspace databases on a remote server, importing from Power Pivot is not supported, data cannot be backed up locally, and the user interface may experience latency during queries.</p> <p>The default setting for this property can be changed on the Data Modeling page in Analysis Services settings in the Tools\Options dialog box. This property cannot be edited when Integrated Workspace Mode is True.</p> |

Using SSMS to Manage the Workspace Database

You can use SQL Server Management Studio (SSMS) to connect to an Analysis Services server that hosts a workspace database. Typically, there is no management of the workspace database necessary; the exception, is to detach or delete a workspace database, which must be done from SQL Server Management Studio. Do not use SQL Server Management Studio to manage the workspace database while the project is open in the model designer. Doing so could lead to data loss.

Create a new tabular model project

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

This article describes how to create a new, blank tabular model project in Visual Studio with Analysis Services projects. After a new model project has been created, you can begin authoring your model project by importing data from data sources.

To create a new, blank tabular model project

1. In Visual Studio with Analysis Services projects, on the **File** menu, click **New**, and then click **Project**.
2. In the **New Project** dialog box, under **Installed Templates**, click **Business Intelligence**, and then click **Tabular Model Project**.
3. In **Name**, type a name for the project, then specify a location and solution name, and then click **OK**.

After your new project is created, it is important to set project and model properties. For more information, see [Project properties](#) and [Model properties](#).

Import from Analysis Services

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to create a new tabular model project by importing the metadata from an existing tabular model by using the Import from Server project template in Visual Studio with Analysis Services projects.

Create a new model by importing metadata from an existing model in Analysis Services

You can use the Import from Server project template to create a new tabular model project by copying the metadata from an existing tabular model on an Analysis Services server. The new project will be created with the same data source connections, tables, relationships, measures, KPIs, roles, hierarchies, perspectives, and partitions as the model it was imported from. The data, however, is not copied from the existing model to the new model workspace. Once the import process has completed, and the new model project created, you must run a Process All to load the data from the data sources into the new model project workspace database.

To create a new model by importing metadata from an existing model

1. In Visual Studio with Analysis Services projects, on the **File** menu, click **New**, and then click **Project**.
2. In the **New Project** dialog box, under **Installed Templates**, click **Business Intelligence**, and then click **Import from Server**.
3. In **Name**, type a name for the project, then specify a location and solution name, and then click **OK**.
4. In the **Import from Analysis Services** dialog box, in **Server Name**, specify the name of the Analysis Services server that contains the model metadata you want to import.
5. In **Database Name**, select the tabular model database that contains the model metadata you want to import, and then click **OK**.

[Project properties](#)

Import from Power Pivot

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to create a new tabular model project by importing the metadata and data from a Power Pivot workbook by using the Import from Power Pivot project template in Visual Studio with Analysis Services projects.

Create a new Tabular Model from a Power Pivot for Excel file

When creating a new tabular model project by importing from a Power Pivot workbook, the metadata that defines the structure of the workbook is used to create and define the structure of the tabular model project in Visual Studio with Analysis Services projects. Objects such as tables, columns, measures, and relationships are retained and will appear in the tabular model project as they are in the Power Pivot workbook. No changes are made to the .xlsx workbook file.

NOTE

Tabular models do not support linked tables. When importing from a Power Pivot workbook that contains a linked table, linked table data is treated as copy\pasted data and stored in the Model.bim file. When viewing properties for a copy\pasted table, the **Source Data** property is disabled and the **Table Properties** dialog on the **Table** menu is disabled.

There is a limit of 10,000 rows that can be added to the data embedded in the model. If you import a model from Power Pivot and see the error, "Data was truncated. Pasted tables cannot contain more than 10000 rows" you should revise the Power Pivot model by moving the embedded data into another data source, such as a table in SQL Server, and then re-import.

There are special considerations depending on whether or not the workspace database is on an Analysis Services instance on the same computer (local) as Visual Studio with Analysis Services projects or is on a remote Analysis Services instance..

If the workspace database is on a local instance of Analysis Services, you can import both the metadata and data from the Power Pivot workbook. The metadata is copied from the workbook and used to create the tabular model project. The data is then copied from the workbook and stored in the project's workspace database (except for copy/pasted data, which is stored in the Model.bim file).

If the workspace database is on a remote Analysis Services instance, you cannot import data from a Power Pivot for Excel workbook. You can still import the workbook metadata; however, this will cause a script to be run on the remote Analysis Services instance. You should only import metadata from a trusted Power Pivot workbook. Data must be imported from sources defined in the data source connections. Copy/pasted and linked table data in the Power Pivot workbook must be copied and pasted into the tabular model project.

To create a new tabular model project from a Power Pivot for Excel file

1. In Visual Studio with Analysis Services projects, on the **File** menu, click **New**, and then click **Project**.
2. In the **New Project** dialog box, under **Installed Templates**, click **Business Intelligence**, and then click **Import from Power Pivot**.
3. In **Name**, type a name for the project, then specify a location and solution name, and then click **OK**.
4. In the **Open** dialog box, select the Power Pivot for Excel file that contains the model metadata and data you want to import, and then click **Open**.

[Workspace Database](#)

Configure default data modeling and deployment properties

10/25/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to configure the default compatibility level, deployment, and workspace database property settings, which can be pre-defined for each new tabular model project you create in Visual Studio with Analysis Services projects. After a new project is created, these properties can still be changed depending on your particular requirements.

To configure the default compatibility level

1. In Visual Studio, click **Tools > Options**.
2. In the **Options** dialog box, expand **Analysis Services Tabular > New project settings**.
3. Configure the following property settings:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---|---------------------------------------|---|
| Default compatibility level for new projects | Depends on projects extension version | This setting specifies the default compatibility level to use when creating a new Tabular model project. To learn more, see Compatibility Level for Tabular models in Analysis Services . |
| Default filter direction | Single direction | Single direction, or one-way, is the traditional many-to-one filter direction between fact and dimensional tables in a relationship. Both directions, or two-way, is a cross-filter that enables the filter context of one relationship to be used as the filter context for another table relationship, with one table common to both relationships. To learn more, see Bi-directional cross filters in tabular models . |
| Compatibility level options | All checked | Specifies compatibility level options for new Tabular model projects and when deploying to another Analysis Services instance. |

To configure the default deployment server property

1. In Visual Studio, click **Tools > Options**.
2. In the **Options** dialog box, expand **Analysis Services Tabular > Deployment**.
3. Configure the following property settings:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------------------------------|-----------------|--|
| Default deployment server | localhost | This setting specifies the default server to use when deploying a model. You can click the down arrow to browse for local network Analysis Services servers you can use or you can type the name of a remote server. |

NOTE

Changes to the Default deployment Server property setting will not affect existing projects created prior to the change.

To configure the default Workspace Database property

It's recommended you leave the default Integrated workspace or specify a local Analysis Services server as the workspace server. For workspace databases on a remote server, data cannot be backed up locally and the user interface may experience latency during queries. To learn more, see [Workspace database](#).

1. In Visual Studio, click **Tools > Options**.
2. In the **Options** dialog box, expand **Analysis Services Tabular > Workspace Database**.
3. Configure the following property settings:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------|-----------------|---|
| Integrated workspace | Selected | Specifies new model projects use an Analysis Services instance built into Visual Studio. |
| Default workspace server | localhost | All available instances of Analysis Services running on the local computer are included in the listbox.

For workspace databases on a remote server, data cannot be backed up locally and the user interface may experience latency during queries. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---|---|---|
| Workspace database retention after the model is closed | Keep workspace databases on disk, but unload from memory | <p>Specifies how a workspace database is retained after a model is closed. A workspace database includes model metadata, the data imported into a model, and impersonation credentials (encrypted). In some cases, the workspace database can be very large and consume a significant amount of memory. By default, workspace databases are removed from memory. When changing this setting, it is important to consider your available memory resources as well as how often you plan to work on the model. This property setting has the following options:</p> <p>Keep workspaces in memory - Specifies to keep workspaces in memory after a model is closed. This option will consume more memory; however, when opening a model in Visual Studio with Analysis Services projects, fewer resources are consumed and the workspace will load faster.</p> <p>Keep workspace databases on disk, but unload from memory - Specifies to keep the workspace database on disk, but no longer in memory after a model is closed. This option will consume less memory; however, when opening a model in Visual Studio with Analysis Services projects, additional resources are consumed and the model will load more slowly than if the workspace database is kept in memory. Use this option when in-memory resources are limited or when working on a remote workspace database.</p> <p>Delete workspace - Specifies to delete workspace database from memory and not keep workspace database on disk after the model is closed. This option will consume less memory and storage space; however, when opening a model in Visual Studio with Analysis Services projects, additional resources are consumed and the model will load more slowly than if the workspace database is kept in memory or on-disk. Use this option when only occasionally working on models.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--|------------------------------------|---|
| Data backup | Keep backup of data on disk | <p>Specifies whether or not a backup of the model data is kept in a backup file. This property setting has the following options:</p> <p>Keep backup of data on disk - Specifies to keep a backup of model data on disk. When the model is saved, the data will also be saved to the backup (ABF) file. Selecting this option can cause slower model save and load times</p> <p>Do not keep backup of database on disk - Specifies to not keep a backup of model data on disk. This option will minimize save and model loading time.</p> |
| Ask new project settings for each new project created | not checked | Specifies no default workspace database type is selected for new projects. |

NOTE

Changes to default model properties will not affect properties for existing models created prior to the change.

Project properties

8/28/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Each tabular model project has deployment options and deployment server properties that specify how the project and model is deployed. For example, the server the model will be deployed to and the deployed model database name. These settings are different from model properties, which affect the model workspace database. The project properties described here are in a modal properties dialog box, different from the properties window used to display other types of properties. To display the modal project properties, in Visual Studio with Analysis Services projects, in **Solution Explorer**, right-click the project, and then click **Properties**.

Project properties

Deployment Options

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------|------------------|--|
| Processing Option | Default | By default, Analysis Services will determine the type of processing required when changes to objects are deployed. This generally results in the fastest deployment time. However, you can also choose to have either full processing or no processing performed with each deployment. |
| Transactional Deployment | False | Specifies whether or not the deployment of the model is transactional. By default, the deployment of all or changed objects is not transactional with the processing of those deployed objects. Deployment can succeed and persist even though processing fails. You can change this to incorporate deployment and processing in a single transaction. |
| Query Mode | In-Memory | Specifies the source from which query results are returned. For more information, see DirectQuery Mode . |

Deployment Server

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------|-----------------|-------------|
|----------|-----------------|-------------|

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|------------------|------------------|---|
| Server | localhost | <p>Specifies an instance of Analysis Services. By default, models are deployed to the default instance of Analysis Services on the local computer. You can change this setting to specify a named instance on the local computer or any instance on any remote computer on which you have permission to create Analysis Services objects. Typically, Administrator permissions.</p> <p>The default setting for this property can be changed using the Default Deployment Server property on the Deployment page in Analysis Server settings in the Tools\Options dialog box. For more information, see Configure default data modeling and deployment properties.</p> |
| Edition | Developer | <p>Specifies the edition of the Analysis Services server to which the model will be deployed. The server edition defines various features that can be incorporated into the project.</p> |
| Database | Model | <p>Specifies the name of the Analysis Services database in which model objects will be instantiated upon deployment. This name will be specified in a data connection or an .rsds data connection file. It is recommended the name reflect the type of analysis that will be performed using the model, for example AdventureWorksSalesModel.</p> <p>To prevent duplicate names for deployed models, you should change the Database property name setting to reflect the purpose of the model. When users connect to the model as a data source, this is the name they will see.</p> |
| Cube Name | Model | <p>Specifies the name of the database cube as shown in a reporting client data connection.</p> |
| Version | 13.0 | <p>Version of the Analysis Services instance where the project will be deployed.</p> |

DirectQuery Options

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------|-----------------|-------------|
|----------|-----------------|-------------|

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------------------|-----------------|--|
| Impersonation Settings | Default | Specifies the credentials used to connect to data sources for a model running in DirectQuery Mode. These credentials are different from impersonation credentials that are used in the default In-Memory mode. For more information, see Impersonation . |

Configure Deployment Options and Deployment Server property settings

1. In Visual Studio with Analysis Services projects, in **Solution Explorer**, right-click the project, and then click **Properties**.
2. In the **Properties** window, click a property, and then type a value or click the down arrow to select a setting option.

Model properties

8/28/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Each tabular model project has model properties that affect how the model you are authoring in SQL Server Development Tools is built, how it is backed up, and how the workspace database is stored. Model properties described here do not apply to models that have already been deployed.

Model properties

Advanced

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------|-----------------|--|
| Build Action | Compile | <p>This property specifies how the file relates to the build and deployment process. This property setting has the following options:</p> <p>Compile - A normal build action occurs. Definitions for model objects will be written to the .asdatabase file.</p> <p>None - The output to the .asdatabase file will be empty.</p> |
| Copy to Output Directory | Do Not Copy | <p>This property specifies the source file will be copied to the output directory. This property setting has the following options:</p> <p>Do not copy - No copy is created in the output directory.</p> <p>Copy always - A copy is always created in the output directory.</p> <p>Copy if newer - A copy is created in the output directory only if there are changes to the model.bim file.</p> |

Miscellaneous

NOTE

Some properties are set automatically when the model is created and cannot be changed.

NOTE

Workspace Server, Workspace Retention, and Data Backup properties have default settings applied when you create a new model project. You can change the default settings for new models on the Data Modeling page in Analysis Server settings in the Tools\Options dialog box. These properties, as well as others, can also be set for each model in the Properties window. For more information, see [Configure default data modeling and deployment properties](#).

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------|--|--|
| Collation | Default collation for the computer for which Visual Studio is installed. | The collation designator for the model. |
| Compatibility Level | Default or other selected when creating the project. | Applies to SQL Server 2012 Analysis Services SP1 or later. Specifies the features and settings available for this model. For more information, see Compatibility Level for Tabular models in Analysis Services . |
| Data Backup | Do not back up to disk | <p>Specifies whether or not a backup of the model data is kept in a backup file. This property setting has the following options:</p> <p>Back up to disk - Specifies to keep a backup of model data on disk. When the model is saved, the data will also be saved to the backup (ABF) file. Selecting this option can cause slower model save and load times</p> <p>Do not back up to disk - Specifies to not keep a backup of model data on disk. This option will minimize save and model loading time.</p> <p>The default setting for this property can be changed on the Data Modeling page in Analysis Server settings in the Tools\Options dialog box.</p> |
| Default filter direction | Single direction | Determines the default filter direction for new relationships. |
| DirectQuery Mode | Off | Specifies whether or not this model operates in DirectQuery Mode. For more information, see DirectQuery Mode . |
| File Name | Model.bim | Specifies the name of the .bim file. The file name should not be changed. |
| Full Path | Path specified when the project was created. | The model.bim file location. This property cannot be set in the Properties window. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------|--|---|
| Language | English | The default language of the model. The default language is determined by the Visual Studio language. This property cannot be set in the Properties window. |
| Workspace Database | The project name, followed by an underscore, followed by a GUID. | The name of the workspace database used for storing and editing the in-memory model for the selected model.bim file. This database will appear in the Analysis Services instance specified in the Workspace Server property. This property cannot be set in the Properties window. For more information, see Workspace Database . |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------------------------|--------------------|--|
| Workspace Retention | Unload from memory | <p>Specifies how a workspace database is retained after a model is closed. A workspace database includes model metadata, the data imported into a model, and impersonation credentials (encrypted). In some cases, the workspace database can be very large and consume a significant amount of memory. By default, workspace databases are unloaded from-memory. When changing this setting, it is important to consider your available memory resources as well as how often you plan to work on the model. This property setting has the following options:</p> <p>Keep in memory - Specifies to keep the workspace database in memory after a model is closed. This option will consume more memory; however, when opening a model, fewer resources are consumed and the workspace database will load faster.</p> <p>Unload from memory - Specifies to keep the workspace database on disk, but no longer in memory after a model is closed. This option will consume less memory; however, when opening a model, additional resources are consumed and the model will load more slowly than if the workspace database is kept in memory. Use this option when in-memory resources are limited or when working on a remote workspace database.</p> <p>Delete workspace - Specifies to delete the workspace database from memory and not keep the workspace database on disk after the model is closed. This option will consume less memory and storage space; however, when opening a model, additional resources are consumed and the model will load more slowly than if the workspace database is kept in memory or on-disk. Use this option when only occasionally working on models.</p> <p>The default setting for this property can be changed on the Data Modeling page in Analysis Server settings in the Tools\Options dialog box.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------------|-----------------|---|
| Workspace Server | localhost | <p>This property specifies the default server that will be used to host the workspace database while the model is being authored. All available instances of Analysis Services running on the local computer are included in the listbox.</p> <p>The default setting for this property can be changed on the Data Modeling page in Analysis Server settings in the Tools\Options dialog box.</p> <p>Note: It is recommended that you always specify a local Analysis Services server as the workspace server. For workspaces databases on a remote server, importing from Power Pivot is not supported, data cannot be backed up locally, and the user interface may experience latency during queries.</p> |

Configure model property settings

1. In SSDT, in **Solution Explorer**, click the **Model.bim** file.
2. In the **Properties** window, click a property, and then type a value or click the down arrow to select a setting option.

Table Properties

8/28/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The properties described here are different from those in the Edit Table Properties dialog box, which define which columns from the source are imported.

Table Properties

Basic

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--------------------------|-------------------|---|
| Connection Name | <connection name> | The name of the connection to the table's data source.

To edit the connection, click the button. |
| Hidden | False | Specifies whether the table is hidden from reporting client field lists. |
| Partitions | | Partitions for the table cannot be displayed in the Properties window. To view, create, or edit partitions, click the button to open the Partition Manager. |
| Source Data | | Source data for the table cannot be displayed in the Properties window. To view or edit the source data, click the button to open the Edit Table Properties dialog box. |
| Table Description | | A text description for the table.

In Power Pivot for Excel, if an end-user places the cursor over this table in the field list, the description appears as a tooltip. |
| Table Name | <friendly name> | Specifies the table's friendly name. The table name can be specified when a table is imported using the Table Import Wizard or at any time after import. The table name in the model can be different from the associated table at the source. The table friendly name appears in the reporting client application field list as well as in the model database in SQL Server Management Studio. |

Reporting Properties

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--------------------------|-----------------|-------------|
| Default Field Set | | |
| Table Behavior | | |

Configure table property settings

1. In the model designer, in Data View, click a table (tab), or, in Diagram View, click a table header.
2. In the **Properties** window, click on a property, and then type a value or click the button for additional configuration options.

Column properties

8/28/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes tabular model column properties.

NOTE

Some properties are not supported in all compatibility levels.

Column properties

Advanced

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-----------------------|-----------------|--|
| Display Folder | | A single or nested folder for organizing columns in a client application field list. |

Basic

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--------------------|-----------------|--|
| Column Name | | The name of the column as it is stored in the model and as it is displayed in a reporting client field list. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--------------------|---|--|
| Data Format | Automatically determined during import. | <p>Specifies the display format to use for the data in this column. This property has the following options:</p> <p>General</p> <p>Decimal Number</p> <p>Whole Number</p> <p>Currency</p> <p>Percentage</p> <p>Scientific</p> <p>After you set a data format, you can set properties that are specific to each format. For example, if you choose the Currency format, you can set the number of visible decimal places, choose the thousands separator, and choose the currency symbol.</p> <p>If the column values contain images, see Representative Image.</p> |
| Data Type | Automatically determined during import. | Specifies the data type for all values in the column. |
| Description | | <p>A text description for the column.</p> <p>In certain reporting clients, if an end-user places the cursor over this column in the field list, the description appears as a tooltip.</p> |
| Hidden | False | <p>Specifies whether the column is hidden from reporting client field lists.</p> <p>Set this property to True to hide this column in the display. For example, columns that contain identifiers or keys are typically not useful to the end user.</p> <p>If you hide a column from the reporting client, the field is not suppressed in the model data. The field is still visible if you create a query against the model. A hidden column can still be used for grouping or sorting.</p> <p>The Hidden property does not provide any form of data security. To secure data, use row filters in Roles. For more information, see Roles.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-----------------------|-----------------|--|
| Sort By Column | | <p>Specifies another column to sort the values in this column. A relationship must exist between the two columns.</p> <p>This value must be the name of an existing column. You cannot specify a formula or measure.</p> |
| Unique | | <p>Can be set to enforce uniqueness of values in the column. Always true for calculated columns, even if uniqueness is false.</p> |

Misc.

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-----------------------|-----------------|---|
| Encoding Hints | Default | <p>Specifies encoding to optimize processing. Value encoding can improve query performance for numeric columns typically used in aggregations. Hash encoding is for group-by columns (often dimension-table values) and foreign keys. String columns are always hash encoded.</p> |

Reporting Properties

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------------------|-----------------|---|
| Default Image | False | <p>Specifies which column provides an image that represents the row data (for example, a photo ID in an employee record).</p> |
| Default Label | False | <p>Specifies which column provides a display name to represent row data (for example, employee name in an employee record).</p> |
| Image URL/Data Category (SP1) | False | <p>Specifies the value in this column as a hyperlink to an image on a server. For example:</p> <div style="border: 1px solid black; padding: 2px; display: inline-block;"> http://localhost/images/image1.jpg </div> |
| Keep Unique Rows | False | <p>Specifies which columns provide values that should be treated as unique even if they are duplicates (for example, employee first name and last name, for cases where two or more employees share the same name).</p> |
| Row Identifier | False | <p>Specifies a column that contains only unique values, allowing that column to be used as an internal grouping key.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-----------------------|----------------------|---|
| Summarize By | Default | Specifies reporting client tools apply the aggregate function SUM for column calculations when this column is added to a Field list. To change the default calculation, select it from the dropdown list. This property applies only to columns of type that can be aggregated. |
| Table Detail Position | No Default Field Set | Specifies this column or measure can be added to a set of fields from a single table to enhance the table visualization experience in a reporting client. |

Configure column property settings

1. In the model designer, in a table, select a column.
2. In the **Properties** window, click on a property, and then type a value or click the down arrow to select a setting option.

Data sources supported in SQL Server Analysis Services tabular 1400 and higher models

11/11/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server 2017 Analysis Services Azure Analysis Services Power BI Premium

This article describes the types of data sources that can be used with SQL Server Analysis Services (SSAS) tabular models at the 1400 and higher compatibility level.

For SSAS tabular models at the 1200 and lower compatibility levels, see [Data sources supported in SQL Server Analysis Services tabular 1200 models](#).

For Azure Analysis Services, see [Data sources supported in Azure Analysis Services](#).

Cloud data sources

| DATASOURCE | IN-MEMORY | DIRECTQUERY |
|---|-----------|-------------|
| Azure SQL Database | Yes | Yes |
| Azure SQL Data Warehouse | Yes | Yes |
| Azure Blob Storage | Yes | No |
| Azure Table Storage | Yes | No |
| Azure Cosmos DB | Yes | No |
| Azure Data Lake Store (Gen1) ¹ | Yes | No |
| Azure HDInsight HDFS | Yes | No |
| Azure HDInsight Spark ² | Yes | No |
| | | |

¹ - ADLS Gen2 is currently not supported.

² - Azure Databricks using the Spark connector is currently not supported.

Provider

In-memory and DirectQuery models connecting to Azure data sources use .NET Framework Data Provider for SQL Server.

On-premises data sources

Supported by in-memory and DirectQuery models

| DATASOURCE | IN-MEMORY PROVIDER | DIRECTQUERY PROVIDER |
|------------|--------------------|----------------------|
| | | |

| DATA SOURCE | IN-MEMORY PROVIDER | DIRECT QUERY PROVIDER | |
|---------------------------|---|---|--|
| SQL Server | SQL Server Native Client
11.0, Microsoft OLE DB Provider for SQL Server, .NET Framework Data Provider for SQL Server | .NET Framework Data Provider for SQL Server | |
| SQL Server Data Warehouse | SQL Server Native Client
11.0, Microsoft OLE DB Provider for SQL Server, .NET Framework Data Provider for SQL Server | .NET Framework Data Provider for SQL Server | |
| Oracle | Microsoft OLE DB Provider for Oracle, Oracle Data Provider for .NET | Oracle Data Provider for .NET | |
| Teradata | OLE DB Provider for Teradata, Teradata Data Provider for .NET | Teradata Data Provider for .NET | |
| | | | |

NOTE

For in-memory models, OLE DB providers can provide better performance for large-scale data. When choosing between different providers for the same data source, try the OLE DB provider first.

Supported by in-memory models only

| DATABASE | | |
|------------------------------|-----|----|
| Access Database | | |
| SQL Server Analysis Services | | |
| IBM Informix (beta) | | |
| JSON document | | |
| Lines from binary | | |
| MySQL Database | | |
| PostgreSQL Database | Yes | No |
| SAP HANA | Yes | No |
| SAP Business Warehouse | Yes | No |
| Sybase Database | Yes | No |
| | | |

| | |
|------------------------|--|
| FILE | |
| Excel workbook | |
| Folder | |
| JSON | |
| Text/CSV | |
| XML table | |
| | |

[Data sources supported in Azure Analysis Services](#)

Data sources supported in SQL Server Analysis Services tabular 1200 models

11/11/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes the types of data sources that can be used with SQL Server Analysis Services tabular models at the 1200 and lower compatibility level.

For models at the 1400 and higher compatibility levels, see [Data sources supported in SQL Server Analysis Services tabular 1400 and higher models](#).

For Azure Analysis Services, see [Data sources supported in Azure Analysis Services](#).

Supported data sources for in-memory tabular models

When you install Visual Studio with Analysis Services projects, setup does not install the providers that are listed for each data source. Some providers might be installed with other applications on your computer. In other cases, you may need to download and install the provider.

| Source | Versions | File type | Providers |
|---------------------------------|--|------------------|---|
| Access databases | Microsoft Access 2010 and later. | .accdb or .mdb | ACE 14 OLE DB provider ¹ |
| SQL Server relational databases | SQL Server 2008 and later, SQL Server Data Warehouse 2008 and later, Azure SQL Database, Azure SQL Data Warehouse, Analytics Platform System (APS) | (not applicable) | Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL) ²
OLE DB Provider for SQL Server (SQLOLEDB) ³
SQL Server Native Client
OLE DB Provider (SQLNCLI) ³
.NET Framework Data Provider for SQL Client |
| Oracle relational databases | Oracle 9i and later. | (not applicable) | Oracle OLE DB Provider
.NET Framework Data Provider for Oracle Client
.NET Framework Data Provider for SQL Server
OraOLEDB
MSDASQL |

| | | | |
|---|--|---|--|
| Teradata relational databases | Teradata V2R6 and later | (not applicable) | TDOLEDB OLE DB provider
.Net Data Provider for Teradata |
| Informix relational databases | | (not applicable) | Informix OLE DB provider |
| IBM DB2 relational databases | 8.1 | (not applicable) | DB2OLEDB |
| Sybase Adaptive Server Enterprise (ASE) relational databases | 15.0.2 | (not applicable) | Sybase OLE DB provider |
| Other relational databases | (not applicable) | (not applicable) | OLE DB provider or ODBC driver |
| Text files | (not applicable) | .txt, .tab, .csv | ACE 14 OLE DB provider ¹ |
| Microsoft Excel files | Excel 2010 and later | .xlsx, xlsm, .xlsb, .xltx, .xltm | ACE 14 OLE DB provider ¹ |
| Power Pivot workbook | Microsoft SQL Server 2008 and later Analysis Services | .xlsx, xlsm, .xlsb, .xltx, .xltm | ASOLEDB 10.5

(used only with Power Pivot workbooks that are published to SharePoint farms that have Power Pivot for SharePoint installed) |
| Analysis Services cube | Microsoft SQL Server 2008 and later Analysis Services | (not applicable) | ASOLEDB 10 |
| Data feeds

(used to import data from Reporting Services reports, Atom service documents, Microsoft Azure Marketplace DataMarket, and single data feed) | Atom 1.0 format

Any database or document that is exposed as a Windows Communication Foundation (WCF) Data Service (formerly ADO.NET Data Services). | .atomsvc for a service document that defines one or more feeds

.atom for an Atom web feed document | Microsoft Data Feed Provider for Power Pivot

.NET Framework data feed data provider for Power Pivot |
| Office Database Connection files | | .odc | |

[1] Using ACE 14 OLE DB provider to connect to file data types is not recommended. If you must retain your tabular 1200 and lower compatibility level models, export your data to a csv file type, import to SQL database, and then connect to and import from the database. However, it's recommended you upgrade to tabular 1400 compatibility level (SQL Server 2017 and later) and use **Get Data** in SSDT to select and import your file data source. Get Data uses structured data source connections provided by the Power Query data engine, which are more stable than ACE 14 OLE DB provider connections.

[2] If deploying a tabular 1200 model to Azure Analysis Services or SQL Server Analysis Services, **it's recommended** you use the updated Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL). For SQL Server Analysis Services, it may be necessary to download and install the MSOLEDBSQL driver on the server. To learn more, see [Microsoft OLE DB Driver for SQL Server](#).

[3] SQL Server Native Client (SQLNCLI) and previous generation OLE DB Provider for SQL Server (SQLOLEDB) are deprecated. It's recommended you use the updated [Microsoft OLE DB Driver for SQL Server](#).

Supported data sources for DirectQuery models

DirectQuery is an alternative to in-memory storage mode, routing queries to and returning results directly from backend data systems rather than storing all data inside the model (and in RAM once the model is loaded).

Because Analysis Services has to formulate queries in the native database query syntax, a smaller subset of data sources is supported for this mode.

| DATA SOURCE | VERSIONS | PROVIDERS |
|---------------------------------|--|---|
| SQL Server relational databases | SQL Server 2008 and later, SQL Server Data Warehouse 2008 and later, Azure SQL Database, Azure SQL Data Warehouse, Analytics Platform System (APS) | Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL) ² , OLE DB Provider for SQL Server (SQLOLEDB) ³ , SQL Server Native Client OLE DB Provider (SQLNCLI) ³ , .NET Framework Data Provider for SQL Client |
| Oracle relational databases | Oracle 9i and later | Oracle OLE DB Provider |
| Teradata relational databases | Teradata V2R6 and later | .Net Data Provider for Teradata |

Tips for choosing data sources

Importing tables from relational databases saves you steps because *foreign key* relationships are used during import to create relationships between tables in the model designer.

Importing multiple tables, and then deleting the ones you don't need, can also save you steps. If you import tables one at a time, you might still need to create relationships between the tables manually.

Columns that contain similar data in different data sources are the basis of creating relationships within the model designer. When using heterogeneous data sources, choose tables that have columns that can be mapped to tables in other data sources that contain identical or similar data.

OLE DB providers can sometimes offer faster performance for large-scale data. When choosing between different providers for the same data source, you should try the OLE DB provider first.

[Data sources supported in Azure Analysis Services](#)

Data types supported in tabular models

9/4/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes the data types that can be used in tabular models, and discusses the implicit conversion of data types when data is calculated or used in a Data Analysis Expressions (DAX) formula.

Data types used in tabular models

When you import data or use a value in a formula, even if the original data source contains a different data type, the data is converted to one of the following data types. Values that result from formulas also use these data types.

In general, these data types are implemented to enable accurate calculations in calculated columns, and for consistency the same restrictions apply to the rest of the data in models.

Formats used for numbers, currency, dates and times should follow the format of the locale that is specified on the client used to work with model data. You can use the formatting options in the model to control the way that the value is displayed.

| Data type in model | Data type in DAX | Description |
|--------------------|--|--|
| Whole Number | A 64 bit (eight-bytes) integer value*

Note:
DAX formulas do not support data types that are too small to hold the minimum value listed in the description. | Numbers that have no decimal places. Integers can be positive or negative numbers, but must be whole numbers between -9,223,372,036,854,775,807 (-2^63+1) and 9,223,372,036,854,775,806 (2^63-2). |
| Decimal Number | A 64 bit (eight-bytes) real number*

Note:
DAX formulas do not support data types that are too small to hold the minimum value listed in the description. | Real numbers are numbers that can have decimal places. Real numbers cover a wide range of values:

Negative values from -1.79E +308 through -2.23E -308

Zero

Positive values from 2.23E -308 through 1.79E + 308

However, the number of significant digits is limited to 17 decimal digits. |
| Boolean | Boolean | Either a True or False value. |
| Text | String | A Unicode character data string. Can be strings, numbers, or dates represented in a text format. |

| | | |
|----------|-----------|---|
| Date | Date/time | Dates and times in an accepted date-time representation.

Valid dates are all dates after March 1, 1900. |
| Currency | Currency | Currency data type allows values between -922,337,203,685,477.5808 to 922,337,203,685,477.5807 with four decimal digits of fixed precision. |
| N/A | Blank | A blank is a data type in DAX that represents and replaces SQL nulls. You can create a blank by using the BLANK function, and test for blanks by using the logical function, ISBLANK. |

* If you attempt to import data that has large numeric values, import might fail with the following error:

In-memory database error: The '<column name>' column of the '<table name>' table contains a value, '1.7976931348623157e+308', which is not supported. The operation has been canceled.

This error occurs because the model designer uses that value to represent nulls. The values in the following list are synonyms to the previous mentioned null value:

| Value |
|-------------------------|
| 9223372036854775807 |
| -9223372036854775808 |
| 1.7976931348623158e+308 |
| 2.2250738585072014e-308 |

Remove the value from your data and try importing again.

NOTE

You cannot import from a **varchar(max)** column that contains a string length of more than 131,072 characters.

Table data type

In addition, DAX uses a *table* data type. This data type is used by DAX in many functions, such as aggregations and time intelligence calculations. Some functions require a reference to a table; other functions return a table that can then be used as input to other functions. In some functions that require a table as input, you can specify an expression that evaluates to a table; for some functions, a reference to a base table is required. For information about the requirements of specific functions, see [DAX Function Reference](#).

Implicit and explicit data type conversion in DAX Formulas

Each DAX function has specific requirements as to the types of data that are used as inputs and outputs. For example, some functions require integers for some arguments and dates for others; other functions require text or

tables.

If the data in the column that you specify as an argument is incompatible with the data type required by the function, DAX in many cases returns an error. However, wherever possible DAX attempts to implicitly convert the data to the required data type. For example:

- You can type a number, for example "123", as a string. DAX parses the string and attempt to specify it as a number data type.
- You can add TRUE + 1 and get the result 2, because TRUE is implicitly converted to the number 1 and the operation 1+1 is performed.
- If you add values in two columns, and one value happens to be represented as text ("12") and the other as a number (12), DAX implicitly converts the string to a number and then does the addition for a numeric result. The following expression returns 44: = "22" + 22
- If you attempt to concatenate two numbers, they are presented as strings and then concatenated. The following expression returns "1234": = 12 & 34

The following table summarizes the implicit data type conversions that are performed in formulas. In general, semantic model designer behaves like Microsoft Excel, and performs implicit conversions whenever possible when required by the specified operation.

Table of implicit data conversions

The type of conversion that is performed is determined by the operator, which casts the values it requires before performing the requested operation. These tables list the operators, and indicate the conversion that is performed on each data type in the column when it is paired with the data type in the intersecting row.

NOTE

Text data types are not included in these tables. When a number is represented as in a text format, in some cases, the model designer attempts to determine the number type and represent it as a number.

Addition (+)

| Operator (+) | INTEGER | CURRENCY | REAL | Date/time |
|--------------|-----------|-----------|-----------|-----------|
| INTEGER | INTEGER | CURRENCY | REAL | Date/time |
| CURRENCY | CURRENCY | CURRENCY | REAL | Date/time |
| REAL | REAL | REAL | REAL | Date/time |
| Date/time | Date/time | Date/time | Date/time | Date/time |

For example, if a real number is used in an addition operation in combination with currency data, both values are converted to REAL, and the result is returned as REAL.

Subtraction (-)

In the following table, the row header is the minuend (left side) and the column header is the subtrahend (right side):

| Operator (-) | INTEGER | CURRENCY | REAL | Date/time |
|--------------|---------|----------|------|-----------|

| | | | | |
|-----------|-----------|-----------|-----------|-----------|
| INTEGER | INTEGER | CURRENCY | REAL | REAL |
| CURRENCY | CURRENCY | CURRENCY | REAL | REAL |
| REAL | REAL | REAL | REAL | REAL |
| Date/time | Date/time | Date/time | Date/time | Date/time |

For example, if a date is used in a subtraction operation with any other data type, both values are converted to dates, and the return value is also a date.

NOTE

Tabular models also support the unary operator, - (negative), but this operator does not change the data type of the operand.

Multiplication (*)

| | | | | |
|--------------|----------|----------|----------|-----------|
| Operator (*) | INTEGER | CURRENCY | REAL | Date/time |
| INTEGER | INTEGER | CURRENCY | REAL | INTEGER |
| CURRENCY | CURRENCY | REAL | CURRENCY | CURRENCY |
| REAL | REAL | CURRENCY | REAL | REAL |

For example, if an integer is combined with a real number in a multiplication operation, both numbers are converted to real numbers, and the return value is also REAL.

Division (/)

In the following table the row header is the numerator and the column header is the denominator.

| | | | | |
|------------------------------|----------|----------|----------|-----------|
| Operator (/)
(Row/Column) | INTEGER | CURRENCY | REAL | Date/time |
| INTEGER | REAL | CURRENCY | REAL | REAL |
| CURRENCY | CURRENCY | REAL | CURRENCY | REAL |
| REAL | REAL | REAL | REAL | REAL |
| Date/time | REAL | REAL | REAL | REAL |

For example, if an integer is combined with a currency value in a division operation, both values are converted to real numbers, and the result is also a real number.

Comparison operators

Only a limited set of mixed data-type combinations for comparison operations is supported. To learn more, see [DAX Operator Reference](#).

Handling of blanks, empty strings, and zero values

The following table summarizes the differences between DAX and in Microsoft Excel, in the way that blanks are handled:

| Expression | DAX | Excel |
|-----------------|----------|----------|
| BLANK + BLANK | BLANK | 0 (zero) |
| BLANK + 5 | 5 | 5 |
| BLANK * 5 | BLANK | 0 (zero) |
| 5/BLANK | Infinity | Error |

Impersonation

10/22/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article provides tabular model authors an understanding of how sign in credentials are used by Analysis Services when connecting to a datasource to import and process (refresh) data.

Configuring impersonation

Where, and in what context a model exists determines how impersonation information is configured. When creating a new model project, impersonation is configured in Visual Studio when you connect to a data source to import data. Once a model is deployed, impersonation can be configured in a model database connection string property by using SQL Server Management Studio (SSMS). For tabular models in Azure Analysis Services, you can use SSMS or the **View as: Script** mode in the browser-based designer to edit the Model.bim file in JSON.

How impersonation is used

Impersonation is the ability of a server application, such as Analysis Services, to assume the identity of a client application. Analysis Services runs using a service account, however, when the server establishes a connection to a datasource, it uses impersonation so that access checks for data import and processing can be performed.

Credentials used for impersonation are different from the credentials you are currently signed in on with. Sign in user credentials are used for particular client-side operations when authoring a model.

It is important to understand how impersonation credentials are specified and secured, as well as the difference between contexts in which both your signed on user credentials are used and when other impersonation credentials are used.

Understanding server-side credentials

When data is imported or processed, impersonation credentials are used to connect to the datasource and fetch the data. This connection is a *server-side* operation running in the context of a client application because the Analysis Services server hosting the workspace database connects to the datasource and fetches the data.

When you deploy a model to an Analysis Services server, if the workspace database is in memory when the model is deployed, the credentials are passed to the Analysis Services server to which the model is deployed. User credentials are never stored on-disk.

When a deployed model processes data from a datasource, the impersonation credentials, persisted in the in-memory database, are used to connect to the datasource and fetch the data. Because this process is handled by the Analysis Services server managing the model database, this connection is again a server-side operation.

Understanding client-side credentials

When authoring a new model or adding a datasource to an existing model, you connect to a datasource and select tables and views to be imported into the model. In the Table Import Wizard or Get Data\Query Designer preview and filter features, you see a sample of the data you import. You can also specify filters to exclude data that isn't needed in the model.

Similarly, for existing models that have already been created, you use the **Table Properties** dialog to preview and filter data imported into a table.

The preview and filter features, **Table Properties**, and **Partition Manager** dialog boxes are an in-process *client-*

side operation; that is, what is done during this operation are different from how the datasource is connected to and data is fetched from the datasource; a server-side operation. The credentials used to preview and filter data are the credentials of the user currently signed on. In-effect, your credentials.

The separation of credentials used during server-side and client-side operations can lead to a mismatch in what you see and what data is fetched during an import or process (a server-side operation). If the credentials you are currently signed in with and the impersonation credentials specified are different, the data you see in the preview and filter features or the **Table Properties** dialog and the data fetched during an import or process can be different, depending on the credentials required by the datasource.

IMPORTANT

When authoring a model, ensure the credentials you are signed in with and the credentials specified for impersonation have sufficient rights to fetch the data from the datasource.

Options

When configuring impersonation, or when editing properties for an existing datasource connection, specify one of the following options:

Tabular 1400 and higher models

| OPTION | DESCRIPTION |
|---------------------------------------|---|
| Impersonate Account | Specifies the model use a Windows user account to import or process data from the datasource. The domain and name of the user account uses the following format:< Domain name >\< User account name >. |
| Impersonate Current User | Specifies data should be accessed from the datasource using the identity of the user who sent the request. This setting applies only to DirectQuery mode. |
| Impersonate Identity | Specifies a username to access the datasource, but doesn't need to specify the account's password. This setting applies only when Kerberos delegation is enabled and specifies the S4U authentication should be used. |
| Impersonate Service Account | Specifies the model use the security credentials associated with the Analysis Services service instance that manages the model. |
| Impersonate Unattended Account | Specifies the Analysis Services engine should use a pre-configured unattended account to access the data. |

IMPORTANT

Impersonate Current User is not supported in some environments. Impersonate Current User is not supported for tabular models deployed to Azure Analysis Services that connect to on-premises data sources. Because an Azure Analysis Services server resource is not connected to an organization's domain, client credentials cannot be authenticated against a data source server in that domain. Azure Analysis Services also does not currently integrate with (Azure) SQL Database support for single sign-on (SSO). Depending on your environment, other impersonation settings also have restrictions. When attempting to use an impersonation setting that is not supported, an error is returned.

Tabular 1200 models

| OPTION | DESCRIPTION |
|--|---|
| Specific Windows user name and password | This option specifies the model use a Windows user account to import or process data from the datasource. The domain and name of the user account uses the following format:<Domain name>\<User account name>. When creating a new model using the Table Import Wizard, this setting is the default option. |
| Service Account | This option specifies the model use the security credentials associated with the Analysis Services service instance that manages the model. |

Security

Credentials used with impersonation are persisted in-memory by the VertiPaq™ engine. Credentials are never written to disk. If the workspace database is not in-memory when the model is deployed, the user is prompted to enter the credentials used to connect to the datasource and fetch data.

NOTE

It is recommended you specify a Windows user account and password for impersonation credentials. A Windows user account can be configured to use least privileges necessary to connect to and read data from the datasource.

Import data by using a native query

10/11/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services (starting with 2017) Azure Analysis Services Power BI Premium

For tabular 1400 models, the new Get Data experience in Visual Studio Analysis Services projects provides immense flexibility in how you can mashup your data during import. This article describes creating a connection to a datasource and then creating a native SQL query to specify data import.

In order to complete the tasks described in this article, make sure you're using the latest version of SSDT. If you're using Visual Studio 2017, make sure you've downloaded and installed the September 2017 or later Microsoft Analysis Services Projects VSIX.

[Download and install SSDT](#)

[Download Microsoft Analysis Services Projects VSIX](#)

Create a datasource connection

If you don't already have a connection to your datasource, you need to create one.

1. In Visual Studio > **Tabular Model Explorer**, right-click **Data Sources**, and then click **New Data Source**.
2. In **Get Data**, select your datasource type, and then click **Connect**. Follow any additional steps required to connect to your datasource.

Enter a query as a named expression

1. In **Tabular Model Explorer**, right-click **Expressions** > **Edit Expressions**.
2. In **Query Editor**, click **Query** > **New Query** > **Blank Query**
3. In the formula bar, type

```
= Value.NativeQuery#"DATA SOURCE NAME", "SELECT * FROM ...")
```

4. To create a table, in **Queries**, right-click the query, and then select **Create New Table**. The new table will have the same name as the query.

Example

This native query creates an Employee table in the model that includes all columns from the Dimension.Employee table at the datasource.

```
= Value.NativeQuery#"SQL/myserver;WideWorldImportersDW", "SELECT * FROM Dimension.Employee")
```

Employee - Query Editor

Home Query Rows Columns Transform Combine View

Import Data Type: Whole Number

Queries [1] Employee

```
= Value.NativeQuery
("#$SQL/myserver;WideWorldImportersDW", "SELECT * FROM
Dimension.Employee")
```

| Employee Key | WWI Employee ID | Employee | Preferred Name |
|--------------|-----------------|--------------------|----------------|
| 0 | 0 | Unknown | N/A |
| 1 | 14 | Lily Code | Lily |
| 2 | 4 | Isabella Rupp | Isabella |
| 3 | 11 | Ethan Onslow | Ethan |
| 4 | 7 | Amy Trefl | Amy |
| 5 | 19 | Jai Shand | Jai |
| 6 | 8 | Anthony Grosse | Anthony |
| 7 | 15 | Taj Shand | Taj |
| 8 | 13 | Hudson Hollinworth | Hudson |
| 9 | 20 | Jack Potter | Jack |
| 10 | | | |
| 11 | | | |

DirectQuery mode in tabular models

10/25/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes *DirectQuery mode* for Analysis Services tabular models at the 1200 and higher compatibility levels. DirectQuery mode can be turned on for models you're designing in Visual Studio, or for tabular models that have already been deployed, you can change to DirectQuery mode in SSMS. Before choosing DirectQuery mode, it's important to understand both the benefits and restrictions.

Benefits

By default, tabular models use an in-memory cache to store and query data. When tabular models query data residing in-memory, even complex queries can be incredibly fast. However, there are some limitations to using cached data. Namely, large data sets can exceed available memory, and data freshness requirements can be difficult if not impossible to achieve on a regular processing schedule.

DirectQuery overcomes these limitations while also leveraging RDBMS features making query execution more efficient. With DirectQuery:

- Data is up-to-date, and there is no extra management overhead of having to maintain a separate copy of the data (in the in-memory cache). Changes to the underlying source data can be immediately reflected in queries against the data model.
- Datasets can be larger than the memory capacity of an Analysis Services server.
- DirectQuery can take advantage of provider-side query acceleration, such as that provided by memory optimized column indexes.
- Security can be enforced by the back-end database, using row-level security features from the database (alternatively, you can use row-level security in the model via DAX).
- If the model contains complex formulas that might require multiple queries, Analysis Services can perform optimization to ensure that the query plan for the query executed against the back-end database will be as efficient as possible.

Restrictions

Tabular models in DirectQuery mode have some restrictions. Before switching modes, it's important to determine whether the advantages of query execution on the backend server outweigh any reduction in functionality.

If you change the mode of an existing model in Visual Studio with Analysis Services projects, the model designer will notify you of any features in your model that are incompatible with DirectQuery mode.

The following list summarizes the main feature restrictions to keep in mind:

| Feature area | Restriction |
|--------------|-------------|
| | |

| | |
|------------------------------|--|
| Data sources | DirectQuery models can only use data from a single relational database of the following types: SQL Server, Azure SQL Database, Oracle, and Teradata. See Data sources supported for DirectQuery later in this article for version and provider information. |
| SQL stored procedures | For DirectQuery models, stored procedures cannot be specified in a SQL statement to define tables when using Data Import Wizard. |
| Calculated tables | Calculated tables are not supported in DirectQuery models, but calculated columns are. If you try to convert a tabular model that contains a calculated table, an error will occur stating that the model cannot contain pasted data. |
| Query limits | Default row limit is one million rows, which you can increase by specifying MaxIntermediateRowSize in the msmdsrv.ini file. See DAX Properties for details. |
| DAX formulas | <p>When querying a tabular model in DirectQuery mode, Analysis Services converts DAX formulas and measure definitions into SQL statements. DAX formulas containing elements that cannot be converted into SQL syntax will return validation errors on the model.</p> <p>This restriction is mostly limited to certain DAX functions. For measures, DAX formulas are converted to set-based operations against the relational data store. This means that all measures created implicitly are supported.</p> <p>When a validation error occurs, you'll need to re-write the formula, substituting a different function, or workaround it by using derived columns in the data source. If a tabular model includes formulas containing incompatible functions will be reported when you switch to DirectQuery mode in the designer.</p> <p>Note: Some formulas in the model might validate when you switch the model to DirectQuery mode, but return different results when executed against the cache vs. the relational data store. This is because calculations against the cache use the semantics of the in-memory analytics (engine, which contains features meant to emulate the behavior of Excel), whereas queries against data stored in the relational data source use the semantics of SQL Server.</p> <p>To learn more, see DAX formula compatibility in DirectQuery mode.</p> |
| Formula consistency | <p>In certain cases, the same formula can return different results in a cached model compared to a DirectQuery model that uses only the relational data store. These differences are a consequence of the semantic differences between the in-memory analytics engine and SQL Server.</p> <p>For a complete list of compatibility issues, including functions that might return different results when the model is deployed to real-time, see DAX formula compatibility in DirectQuery mode (SQL Server Analysis Services).</p> |

| | |
|------------------------|--|
| MDX limitations | No relative object names. All object names must be fully qualified. |
| | No session-scope MDX statements (named sets, calculated members, calculated cells, visual totals, default members, and so forth), but you can use query-scope constructs, such as the 'WITH' clause. |
| | No tuples with members from different levels in MDX subselect clauses. |
| | No user-defined hierarchies. |
| | No native SQL queries (normally, Analysis Services supports a T-SQL subset, but not for DirectQuery models). |

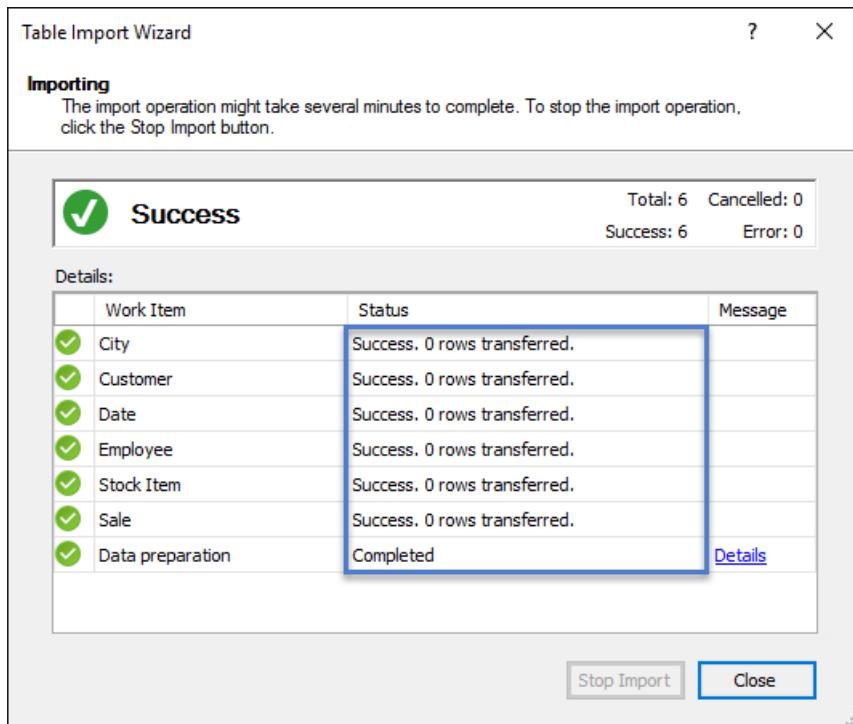

Data sources supported for DirectQuery

See [Data sources supported in SQL Server Analysis Services tabular 1400 models](#)

Connecting to a data source

When designing a DirectQuery model in Visual Studio, connecting to a data source and selecting the tables and fields to include in your model is much the same as with in-memory models.

If you've already turned on DirectQuery but haven't yet connected to a data source, you can use the Table Import Wizard to connect to your data source, select tables and fields, specify a SQL query, and so on. The difference will be when you finish, no data is actually imported to the in-memory cache.

If you've already used Table Import Wizard to import data, but haven't yet turned on DirectQuery mode, when you do, the in-memory cache will be cleared.

Deploying DirectQuery models

DirectQuery models are deployed the same as import models. However, unlike import models, if a DirectQuery

model contains calculated items, calculated columns, calculated tables, after being deployed you must perform a **Process Recalc** on the database. To learn more about processing a model database from SSMS, see [Process Database, Table, or Partition](#).

Enable DirectQuery mode in SSDT

8/6/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services ✓ Azure Analysis Services ✗ Power BI Premium

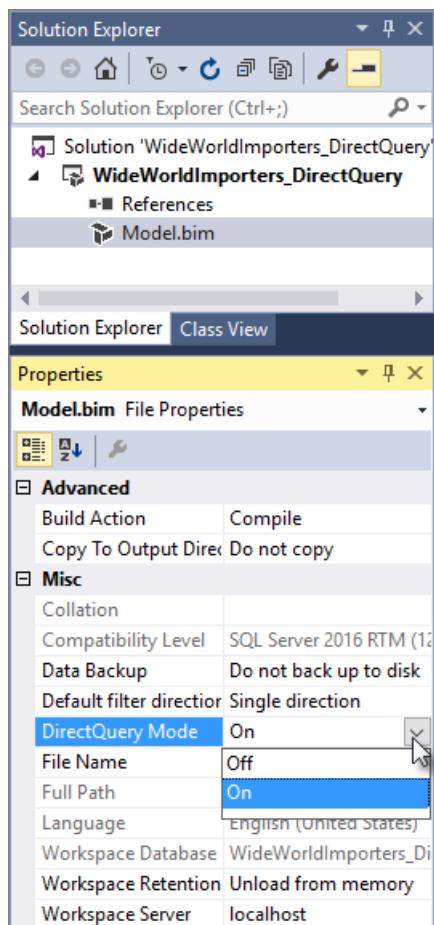

In this topic, we'll describe how to enable DirectQuery mode for a tabular model project in Visual Studio with Analysis Services projects.

When you enable DirectQuery mode for a tabular model you're designing in SSDT:

- Features that are incompatible with DirectQuery mode are disabled.
- The existing model is validated. Warnings are displayed if features are incompatible with DirectQuery mode.
- If data was previously imported prior to enabling DirectQuery mode, the working model's cache is emptied.

Enable DirectQuery

In SSDT, in the **Properties** pane for the **Model.bim** file, change the property, **DirectQuery Mode**, to **On**.

If your model already has a connection to a data source and existing data, you'll be prompted to enter database credentials used to connect to the relational database. Any data already existing within the model will be removed from the in-memory cache.

If your model is partially or fully complete prior to enabling DirectQuery mode, you might get errors about incompatible features. In Visual Studio, open the **Error List** and resolve any problems that would prevent the model from being switched to DirectQuery mode.

What's next?

You can now import data using the Table Import Wizard to get metadata for the model. You won't get rows of data,

but you will get tables, columns, and relationships to use as the basis for your model.

You can create a sample partition for each table and add sample data so that you can verify model behavior as you build it. Any sample data that you add is used in **Analyze for Excel** or in other client tools that can connect to the workspace database. See [Add sample data to a DirectQuery model in design mode](#) for details.

TIP

Even in DirectQuery mode on an empty model, you can always view a small built-in rowset for each table. In Visual Studio with Analysis Services projects, click **Table > Table Properties** to view the 50-row dataset.

[Enable DirectQuery mode in SSMS](#)

[Add sample data to a DirectQuery model in design mode](#)

Enable DirectQuery mode in SSMS

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can change the data access properties of a tabular model that has already been deployed, enabling DirectQuery mode, where queries execute against a backend relational data source rather than cached data residing in-memory.

In SQL Server 2017, steps for DirectQuery configuration differ based on the model's compatibility level. Below you'll find steps that work for all compatibility levels.

This article assumes that you have created and validated an in-memory tabular model at compatibility level 1200 or higher, and only need to enable DirectQuery access and update connection strings. If you're starting from a lower compatibility level, you need to manually upgrade it first. See [Upgrade Analysis Services](#) for steps.

IMPORTANT

We recommend using Visual Studio with Analysis Services projects instead of Management Studio to switch data storage modes. When you use Visual Studio with Analysis Services projects to change model, and then follow that up with deployment to the server, the model and database stay in sync. Moreover, changing the storage modes in the model lets you review any validation errors that occur. When using SQL Server Management Studio as described in this article, validation errors are not reported.

Requirements

Enabling the use of Direct Query mode on a tabular model is a multistep process:

- Ensure that the model does not have features which might cause validation errors in DirectQuery mode, and then change the data storage mode on the model from in-memory to DirectQuery.
A list of feature restrictions is documented in [DirectQuery Mode](#).
- Review the connection string and credentials used by the deployed database to retrieve data from the backend external database. Make sure there is only one connection, and that its settings are suitable for query execution.

Tabular databases that weren't specifically designed for DirectQuery could have multiple connections which now need to be reduced to one, as required for DirectQuery mode.

Credentials originally used for processing data will now be used to query data. As part of DirectQuery configuration, review and possibly change the account if you use different ones for dedicated operations.

DirectQuery mode is the only scenario in which Analysis Services does trusted delegation. If your solution calls for delegation to get user-specific query results, the account used to connect to the backend database must be allowed to delegate the identity of the user making the request, and user identities must have Read permissions on the backend database.

- As a last step, confirm that DirectQuery mode is operational through query execution.

Step 1: Check the compatibility level

Properties that define data access are different across compatibility levels. A preliminary step is to check to see

what compatibility level the database is at.

1. In Management Studio, connect to the instance that has the tabular model.
2. In Object Explorer, right-click the database > **Properties** > **Compatibility Level**.

The value will either be **SQL Server 2016 (1200)** or an earlier level like **SQL Server 2012 SP1 or later (1103)**. In the next step, follow the instructions that are valid for the compatibility level.

When you change a tabular model to DirectQuery mode, the new data storage mode takes effect immediately.

Step 2a: Switch a tabular 1200 database to DirectQuery mode

1. In Object Explorer, right-click the database > **Properties** > **Model** > **Default Mode**.
2. Set the mode to **DirectQuery**.

| Valid values | Description |
|--------------------|--|
| DirectQuery | <p>Queries are executed against a backend relational database, using the data source connection defined for the model.</p> <p>Queries to the model are converted to native database queries and redirected to the data source.</p> <p>When you process a model set to DirectQuery mode, only metadata is compiled and deployed. The data itself is external to the model, residing in the database files of the operative data source.</p> |
| Import | <p>Queries are executed against the tabular database in either MDX or DAX.</p> <p>When you process a model set to Import mode, data is retrieved from a backend data source and stored on disk. When the database is loaded, data is copied entirely into memory for very fast table scans and queries.</p> <p>This is the default mode for tabular models, and it is the only mode for certain (non-relational) data sources.</p> |

Step 2b: Switch a tabular 1100-1103 database to DirectQuery mode

1. In Object Explorer, right-click the database > **Properties** > **Database** > **DirectQueryMode**.
2. Set the mode to **DirectQuery**.

Default Mode properties consist of the following:

| Valid values | Description |
|-----------------|--|
| InMemory | Queries use the cached, in-memory data only. |

| | |
|--------------------------------|---|
| InMemorywithDirectQuery | Queries use the cache by default, unless otherwise specified in the connection string from the client. |
| | This is a hybrid mode where partitions are individually configured to use in-memory or DirectQuery. |
| DirectQuery | Queries use the relational data source only. |
| DirectQuerywithInMemory | Queries use the relational data source by default, unless otherwise specified in the connection string from the client. |
| | This is a hybrid mode where partitions are individually configured to use in-memory or DirectQuery. |

Hybrid Data Storage

When using combination of in-memory and disk-based access, the cache is still available and can be used for queries. A hybrid mode provides you with many options:

- When both the cache and the relational data source are available, you can set the preferred connection method, but ultimately the client controls which source is used, using the DirectQueryMode connection string property.
- You can configure partitions on the cache in such a way that the primary partition used for DirectQuery mode is never processed and must always reference the relational source. There are many ways to use partitions to optimize the model design and reporting experience. For more information, see [Define partitions in DirectQuery models](#).
- After the model has been deployed, you can change the preferred connection method. For example, you might use a hybrid mode for testing, and switch the model over to **DirectQuery only** mode only after thoroughly testing any reports or queries that use the model. For more information, see [Set or Change the Preferred Connection Method for DirectQuery](#).

Step 3: Check the connection properties on the database

Depending on how the data source connection is set up, switching to DirectQuery could change the security context of the connection. When changing the data access mode, review impersonation and connection string properties to verify the login is valid for ongoing connections to the backend database.

Review the **Configure Analysis Services for trusted delegation** section in [Configure Analysis Services for Kerberos constrained delegation](#) for background information on delegation of a user identity for DirectQuery scenarios.

1. In Object Explorer, expand **Connections** and double-click a connection to view its properties.

For DirectQuery models, there should only be one connection defined for the database, and the data source must be relational, and of a supported database type. See [Data Sources Supported](#).

2. **Connection string** should specify the server, database name, and the authentication method used in DirectQuery operations. If you're using SQL Server authentication, you can specify the database login here.
3. **Impersonation Info** is used for Windows authentication. Options that are valid for tabular models in DirectQuery mode include the following:
 - **Use the service account**. You can choose this option if the Analysis Services service account has read permissions on the relational database.

- **Use a specific user name and password.** Specify a Windows user account that has read permissions on the relational database.

Note that these credentials are used only for answering queries against the relational data store; they are not the same as the credentials used for processing the cache of a hybrid model.

Impersonation cannot be used when the model is used within memory only. The setting **ImpersonateCurrentUser**, is invalid unless the model is using DirectQuery mode.

Step 4: Validate DirectQuery access

1. Start a trace using either SQL Server Profiler or xEvents in Management Studio, connected to the relational database on SQL Server.

If you are using Oracle or Teradata, use the tracing tools for those database platforms.

2. In Management Studio, enter and then execute a simple MDX query, such as

```
select <some measure> on 0 from model. .
```

3. In the trace, you should see evidence of query execution on the relational database.

Add sample data to a DirectQuery model in Design Mode

10/22/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: ✓ SQL Server Analysis Services ✓ Azure Analysis Services ✗ Power BI Premium

In DirectQuery mode, table partitions are used to either create sample data subsets used during model design, or create alternatives of a full data view.

When you deploy a DirectQuery tabular model, only one partition is allowed per table, and that partition by necessity must be full data view. Any additional partition is either a substitute for a full data view or sample data. In this topic, we're going to describe creating a sample partition, with a subset of data.

By default, when designing a tabular model in DirectQuery mode in SSDT, the model's working database doesn't contain any data. There is one default partition for each table, and this partition directs all queries to the data source.

You can, however, add a smaller amount of sample data to your model's working database for use at design time. Sample data is specified via a query on a sample partition used only during design. It's cached in-memory with the model. This will help you validate modeling decisions as you go without impacting the data source. You can test your modeling decisions with the sample dataset when using **Analyze in Excel** in Visual Studio, or from other client applications that connect to your workspace database.

TIP

Even in DirectQuery mode on an empty model, you can always view a small built-in rowset for each table. In Visual Studio with Analysis Services projects, click **Table > Table Properties** to view the 50-row dataset.

Create a sample partition

These instructions are for tabular models created at or upgraded to compatibility level 1200 or higher. Models at lower compatibility levels use different properties to get cached data. See [Enable DirectQuery mode in SSMS](#) for property descriptions.

1. In SQL Server Data Tools, in Diagram or Data View, click a fact table to open its properties page. Fact tables provide the aggregated, numeric data and measures in your model. You might have more than one.
2. Click **Table > Properties** to open the Partition Management dialog box.

Notice the default partition is **(Direct Query) <table name>**. This is the full data view. Do not delete this partition. This partition will be used when the model is deployed.

3. Select the partition and then click **Copy**.

This creates a copy of the default partition, however, this copy will contain sample data you specify in a query. For example:

| Partition Name |
|---|
| (DirectQuery) FactInternetSales |
| *(Sample) FactInternetSales - Copy |

4. Select the copied partition and then click the **SQL Query Editor** button to add a filter. Reduce your sample

data size while authoring your model. For example, if you selected **FactInternetSales** from AdventureWorksDW, your filter might look like the following:

```
SELECT [dbo].[FactInternetSales].* FROM [dbo].[FactInternetSales]
JOIN DimSalesTerritory as ST
ON ST.SalesTerritoryKey = FactInternetSales.SalesTerritoryKey
WHERE ST.SalesTerritoryGroup='North America';
```

5. Click **Validate** to check for syntax errors.

Notice in DirectQuery mode, in addition to **New**, **Copy**, and **Delete** buttons on the Partitions dialog box, there is also a toggle button that alternately reads **Set as Sample** or **Set as DirectQuery**.

Only one partition can be the DirectQuery partition. You can control it by selecting any partition defined for the table and clicking **Set as Sample**.

6. Process the table .

Define partitions in DirectQuery models

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This section explains how partitions are used in DirectQuery models. For more general information about partitions in tabular models, see [Partitions](#).

NOTE

Although a table can have multiple partitions, in DirectQuery mode, only one of them can be designated for use in query execution. The single partition requirement applies to DirectQuery models at all compatibility levels.

Using Partitions in DirectQuery Mode

For each table, you must specify a single partition to use as the DirectQuery data source. If there are multiple partitions, when you switch the model to enable DirectQuery mode, by default the first partition that was created in the table is flagged as the DirectQuery partition. You can change this later by using the Partition Manager in Visual Studio with Analysis Services projects.

Why allow only a single partition in DirectQuery mode?

In tabular models (as in OLAP models), the partitions of a table are defined by SQL queries. The developer who creates the partition definition is responsible for ensuring that partitions do not overlap. Analysis Services does not check whether records belong in one or multiple partitions.

Partitions in a cached tabular model behave the same way. If you are using an in-memory model, while the cache is being accessed, DAX formulas are evaluated for each partition, and the results are combined. However, when a tabular model uses DirectQuery mode, it would be impossible to evaluate multiple partitions, combine the results, and convert that into a SQL statement for sending to the relational data store. Doing so could lead to unacceptable loss of performance, as well as potential inaccuracies as the results are aggregated.

Therefore, for queries answered in DirectQuery mode, the server uses a single partition that has been marked as the primary partition for DirectQuery access, called the *DirectQuery partition*. The SQL query specified in the definition of this partition defines the complete set of data that can be used to answer queries in DirectQuery mode.

If you do not explicitly define a partition, the engine simply issues a SQL query to the entire relational data source, performs any set-based operations dictated by the DAX formula, and returns the query results.

Change a DirectQuery Partition

Because only one partition in a table can be designated as the DirectQuery partition, by default, Analysis Services uses the first partition that was created in the table. During model project authoring, you can change the DirectQuery partition by using the Partition Manager dialog box in Visual Studio with Analysis Services projects. For deployed models, you can change the DirectQuery partition by using SQL Server Management Studio.

Change the DirectQuery partition for a tabular model project

1. In Visual Studio with Analysis Services projects, in the model designer, click on the table (tab) that contains the partitioned table.
2. Click on the **Table** menu, and then click **Partitions**.

- In **Partition Manager**, the partition that is the current Direct Query partition is indicated by the prefix **(DirectQuery)** on the partition name.

Select a different partition from the **Partitions** list, and then click **Set as DirectQuery**. The **Set as DirectQuery** button is not enabled when the current DirectQuery partition is selected, and is not visible if the model has not been enabled for Direct Query mode.

- If necessary, change the processing options, and then click **OK**.

Change the DirectQuery partition for a deployed tabular model

- In SQL Server Management Studio, open the model database in Object Explorer.

- Expand the **Tables** node, then right-click the partitioned table, and then select **Partitions**.

The partition that is designated for use with DirectQuery mode has the prefix (DirectQuery) on the partition name.

- To change to a different partition, click the **Direct Query** toolbar icon to open the **Set DirectQuery Partition** dialog box. The DirectQuery toolbar icon is not available on models that have not been enabled for Direct Query.
- Choose a different partition from the **Partition Name** dropdown list, and then change processing options on the partition if necessary.

Partitions in Cached Models and in DirectQuery Models

When you configure a DirectQuery partition, you must specify processing options for the partition.

There are two processing options for the DirectQuery partition. To set this property, use the **Partition Manager** in Visual Studio with Analysis Services projects, or SQL Server Management Studio, and select the **Processing Option** property. The following table lists the values of this property, and describes the effects of each value when combined with the DirectQueryUsage property on the connection string:

| CONNECTION STRING PROPERTY | PROCESSING OPTION PROPERTY | NOTES |
|--|---------------------------------|---|
| DirectQuery | Never process this partition | <p>When the model is using DirectQuery only, processing is never necessary.</p> <p>In hybrid models, you can configure the DirectQuery partition to never be processed. For example, if you are operating over a very large data set and do not want the full results added to the cache, you can specify that the DirectQuery partition include the union of results for all other partitions in the table, and then never process the union. Queries that go to the relational source will not be affected, and queries against cached data will combine data from the other partitions</p> |
| DataView=Sample

Applies to Tabular models using sample data views | Allow partition to be processed | If the model is using sample data, you can process the table to return a filtered dataset that provides visual cues during model design. |

| CONNECTION STRING PROPERTY | PROCESSING OPTION PROPERTY | NOTES |
|---|---------------------------------|---|
| DirectQueryUsage=InMemory With DirectQuery

Applies to Tabular 1100 or 1103 models running in a combination of in-memory and DirectQuery mode | Allow partition to be processed | If the model is using hybrid mode, you should use the same partition for queries against the in-memory and DirectQuery data source. |

Test a model in DirectQuery mode

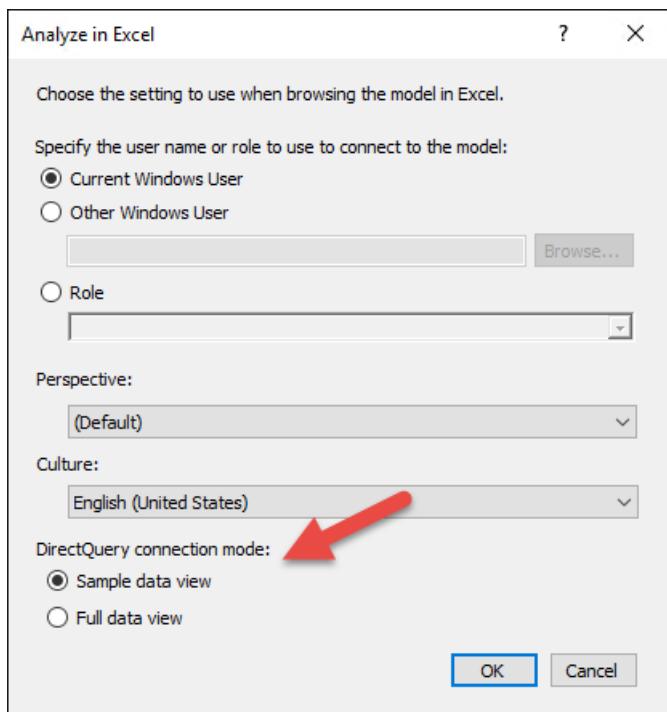

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Review your options for testing a tabular model in DirectQuery mode at each stage of development, starting with design.

Test in Excel

When designing your model in SSDT, you can use the **Analyze in Excel** feature to test your modeling decisions against a sample dataset in-memory, or against the relational database. When you click Analyze in Excel, a dialog box opens where you can specify options.

If your model's DirectQuery mode is on, you can specify DirectQuery connection mode, where you'll have two options:

- **Sample data view** - With this option, any queries from Excel are directed to sample partitions containing a sample dataset in-memory. This option is helpful when you want to make sure any DAX formulas you have in measures, calculated columns, or row-level security perform correctly.
- **Full data view** - With this option, any queries from Excel are sent to Analysis Services, and then on to the relational database. This option is, in-effect, fully functioning DirectQuery mode.

Other clients

When you use Analyze in Excel, an .odc connection file is created. You can use the connection string information from this file to connect to your model from other client applications. An additional parameter, `DataView=Sample`, is added to specify the client should connect to sample data partitions.

Monitor query execution on backend systems using xEvents or SQL Profiler

Start up a session trace, connected to the SQL Server relational database, to monitor connections coming from the Tabular model:

- [Monitor Analysis Services with SQL Server Extended Events](#)
- [Use SQL Server Profiler to Monitor Analysis Services](#)

If you're using Oracle or Teradata, use the trace monitoring tools for those systems.

DAX formula compatibility in DirectQuery mode

10/22/2019 • 17 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

For tabular 1200 and higher models in DirectQuery mode, many functional limitations in earlier versions no longer apply. For DAX formulas in-particular:

- DirectQuery now generates simpler queries, providing improved performance.
- Row level security (RLS) is now supported in DirectQuery mode.
- Calculated columns are now supported for tabular models in DirectQuery mode.

DAX functions in DirectQuery mode

In short, all DAX functions are supported for DirectQuery models. However, not all functions are supported for all formula types, and not all functions have been optimized for DirectQuery models. At the most basic level, we can put DAX functions into two camps: Optimized and Non-optimized. Let's first take a closer look at optimized functions.

Optimized for DirectQuery

These are functions that primarily return scalar or aggregate results. These functions are further divided into those that are supported in all types of formulas: measures, queries, calculated columns, row level security, and those that are supported in measure and query formulas only. These include:

| SUPPORTED IN ALL DAX FORMULAS | SUPPORTED IN MEASURE AND QUERY FORMULAS ONLY |
|-------------------------------|--|
| ABS | ALL |
| ACOS | ALLEXCEPT |
| ACOT | ALLNOBLANKROW |
| AND | ALLSELECTED |
| ASIN | AVERAGE |
| ATAN | AVERAGEA |
| BLANK | AVERAGEEX |
| CEILING | CALCULATE |
| CONCATENATE | CALCULATETABLE |
| COS | COUNT |
| COT | COUNTA |
| CURRENCY | COUNTAX |
| DATE | COUNTROWS |
| DATEDIFF | COUNTX |
| DATEVALUE | DISTINCT |
| DAY | DISTINCTCOUNT |
| DEGREES | FILTER |
| DIVIDE | FILTERS |
| EDATE | HASONEFILTER |
| EOMONTH | HASONEVALUE |
| EXACT | ISCROSSFILTERED |
| EXP | ISFILTERED |
| FALSE | MAXA |
| FIND | MAXX |
| HOUR | MIN |
| IF | MINA |
| INT | MINX |
| ISBLANK | RELATEDTABLE |
| ISO.CEILING | STDEV.P |
| KEEPFILTERS | STDEV.S |

| LEFT
SUPPORTED IN ALL DAX FORMULAS
LEN | STDEVX.P
SUPPORTED IN MEASURE AND QUERY FORMULAS ONLY
STDEVX.S |
|--|--|
| LN | SUM |
| LOG | SUMX |
| LOG10 | VALUES |
| LOWER | VAR.P |
| MAX | VAR.S |
| MID | VARX.P |
| MIN | VARX.S |
| MINUTE | |
| MOD | |
| MONTH | |
| MROUND | |
| NOT | |
| NOW | |
| OR | |
| PI | |
| POWER | |
| QUOTIENT | |
| RADIANS | |
| RAND | |

| SIN | |
| SQRT | |
| SQRTPI | |
| SUBSTITUTE | |
| SWITCH | |
| TAN | |
| TIME | |
| TIMEVALUE | |
| TODAY | |
| TRIM | |
| TRUE | |
| TRUNC | |
| UNICODE | |
| UPPER | |
| USERNAME | |
| USERELATIONSHIP | |
| VALUE | |
| WEEKDAY | |
| WEEKNUM | |
| YEAR | |

Non-optimized for DirectQuery

These functions have not been optimized to work with DirectQuery. These functions *are not supported* in calculated column and row-level security formulas at all. However, these functions *are supported* in measure and query formulas, albeit with uncertain performance.

We're not going to list all of the functions here. Basically, if it's not in one of the lists of optimized functions above, it's a non-optimized function for DirectQuery.

The reasons a particular function might not be optimized for DirectQuery is because the underlying relational engine cannot perform calculations equivalent to those performed by the VertiPaq engine, or the formula cannot be converted to an equivalent SQL expression. In other cases, the performance of the converted expression and

the resulting calculations may be unacceptable.

To learn about all DAX functions, see the [DAX Function Reference](#).

DAX operators in DirectQuery mode

All DAX comparison and arithmetic operators are fully supported in DirectQuery mode. To learn more, see [DAX Operator Reference](#).

Differences between in-memory and DirectQuery mode

Queries on a model deployed in DirectQuery mode can return different results than the same model deployed in in-memory mode. This is because with DirectQuery, data is queried directly from a relational data store and aggregations required by formulas are performed using the relevant relational engine (SQL, Oracle, Teradata), rather than using the VertiPaq in-memory analytics engine for storage and calculation.

For example, there are differences in the way that certain relational data stores handle numeric values, dates, nulls, and so forth.

In contrast, the DAX language is intended to emulate as closely as possible the behavior of functions in Microsoft Excel. For example, when handling nulls, empty strings and zero values, Excel attempts to provide the best answer regardless of the precise data type, and therefore the VertiPaq engine does the same. However, when a tabular model is deployed in DirectQuery mode and passes formulas to a relational data source, the data must be handled according to the semantics of the relational data source, which typically require distinct handling of empty strings vs. nulls. For this reason, the same formula might return a different result when evaluated against cached data and against data returned solely from the relational store.

Additionally, some functions aren't optimized for DirectQuery mode because the calculation would require the data in the current context be sent to the relational data source as a parameter. For example, measures using time-intelligence functions that reference date ranges in a calendar table. A relational data source might not have a calendar table, or at least one with .

Semantic differences

This section lists the types of semantic differences that you can expect, and describes any limitations that might apply to the usage of functions or to query results.

Comparisons

DAX in in-memory models support comparisons of two expressions that resolve to scalar values of different data types. However, models that are deployed in DirectQuery mode use the data types and comparison operators of the relational engine, and therefore might return different results.

The following comparisons will always return an error when used in a calculation on a DirectQuery data source:

- Numeric data type compared to any string data type
- Numeric data type compared to a Boolean value
- Any string data type compared to a Boolean value

In general, DAX is more forgiving of data type mismatches in in-memory models and will attempt an implicit cast of values up to two times, as described in this section. However, formulas sent to a relational data store in DirectQuery mode are evaluated more strictly, following the rules of the relational engine, and are more likely to fail.

Comparisons of strings and numbers

EXAMPLE: `"2" < 3`

The formula compares a text string to a number. The expression is **true** in both DirectQuery mode and in-memory models.

In an in-memory model, the result is **true** because numbers as strings are implicitly cast to a numerical data type for comparisons with other numbers. SQL also implicitly casts text numbers as numbers for comparison to numerical data types.

Note that this represents a change in behavior from the first version of Power Pivot, which would return **false**, because the text "2" would always be considered larger than any number.

Comparison of text with Boolean

EXAMPLE: `"VERDADERO" = TRUE`

This expression compares a text string with a Boolean value. In general, for DirectQuery or In-Memory models, comparing a string value to a Boolean value results in an error. The only exceptions to the rule are when the string contains the word **true** or the word **false**; if the string contains any of true or false values, a conversion to Boolean is made and the comparison takes place giving the logical result.

Comparison of nulls

EXAMPLE: `EVALUATE ROW("X", BLANK() = BLANK())`

This formula compares the SQL equivalent of a null to a null. It returns **true** in in-memory and DirectQuery models; a provision is made in DirectQuery model to guarantee similar behavior to in-memory model.

Note that in Transact-SQL, a null is never equal to a null. However, in DAX, a blank is equal to another blank. This behavior is the same for all in-memory models. It is important to note that DirectQuery mode uses, most of, the semantics of SQL Server; but, in this case it separates from it giving a new behavior to NULL comparisons.

Casts

There is no cast function as such in DAX, but implicit casts are performed in many comparison and arithmetic operations. It is the comparison or arithmetic operation that determines the data type of the result. For example,

- Boolean values are treated as numeric in arithmetic operations, such as `TRUE + 1`, or the function `MIN` applied to a column of Boolean values. A `NOT` operation also returns a numeric value.
- Boolean values are always treated as logical values in comparisons and when used with `EXACT`, `AND`, `OR`, `&&`, or `||`.

Cast from string to Boolean

In in-memory and DirectQuery models, casts are permitted to Boolean values from these strings only: `""` (empty string), `"true"`, `"false"`; where an empty string casts to false value.

Casts to the Boolean data type of any other string results in an error.

Cast from string to date/time

In DirectQuery mode, casts from string representations of dates and times to actual **datetime** values behave the same way as they do in SQL Server.

Models that use the in-memory data store support a more limited range of text formats for dates than the string formats for dates that are supported by SQL Server. However, DAX supports custom date and time formats.

Cast from string to other non Boolean values

When casting from strings to non-Boolean values, DirectQuery mode behaves the same as SQL Server. For more information, see [CAST and CONVERT \(Transact-SQL\)](#).

Cast from numbers to string not allowed

EXAMPLE: `CONCATENATE(102, ",345")`

Casting from numbers to strings is not allowed in SQL Server.

This formula returns an error in tabular models and in DirectQuery mode; however, the formula produces a result in Power Pivot.

No support for two-try casts in DirectQuery

In-memory models often attempt a second cast when the first one fails. This never happens in DirectQuery mode.

EXAMPLE: `TODAY() + "13:14:15"`

In this expression, the first parameter has type **datetime** and second parameter has type **string**. However, the casts when combining the operands are handled differently. DAX will perform an implicit cast from **string** to **double**. In in-memory models, the formula engine attempts to cast directly to **double**, and if that fails, it will try to cast the string to **datetime**.

In DirectQuery mode, only the direct cast from **string** to **double** will be applied. If this cast fails, the formula will return an error.

Math functions and arithmetic operations

Some mathematical functions will return different results in DirectQuery mode because of differences in the underlying data type or the casts that can be applied in operations. Also, the restrictions described above on the allowed range of values might affect the outcome of arithmetic operations.

Order of addition

When you create a formula that adds a series of numbers, an in-memory model might process the numbers in a different order than a DirectQuery model. Therefore, when you have many very large positive numbers and very large negative numbers, you may get an error in one operation and results in another operation.

Use of the POWER function

EXAMPLE: `POWER(-64, 1/3)`

In DirectQuery mode, the POWER function cannot use negative values as the base when raised to a fractional exponent. This is the expected behavior in SQL Server.

In an in-memory model, the formula returns -4.

Numerical overflow operations

In Transact-SQL, operations that result in a numerical overflow return an overflow error; therefore, formulas that result in an overflow also raise an error in DirectQuery mode.

However, the same formula when used in an in-memory model returns an eight-byte integer. That is because the formula engine does not perform checks for numerical overflows.

LOG functions with blanks return different results

SQL Server handles nulls and blanks differently than the VertiPaq engine. As a result, the following formula returns an error in DirectQuery mode, but return infinity (-inf) in in-memory mode.

EXAMPLE: `LOG(blank())`

The same limitations apply to the other logarithmic functions: LOG10 and LN.

For more information about the **blank** data type in DAX, see [DAX Syntax Reference](#).

Division by 0 and division by Blank

In DirectQuery mode, division by zero (0) or division by BLANK will always result in an error. SQL Server does not support the notion of infinity, and because the natural result of any division by 0 is infinity, the result is an error. However, SQL Server supports division by nulls, and the result must always equal null.

Rather than return different results for these operations, in DirectQuery mode, both types of operations (division by zero and division by null) return an error.

Note that, in Excel and in Power Pivot models, division by zero also returns an error. Division by a blank returns a

blank.

The following expressions are all valid in in-memory models, but will fail in DirectQuery mode:

1/BLANK

1/0

0.0/BLANK

0/0

The expression `BLANK/BLANK` is a special case that returns `BLANK` in both for in-memory models, and in DirectQuery mode.

Supported numeric and date-time ranges

Formulas in in-memory tabular model are subject to the same limitations as Excel with regard to maximum allowed values for real numbers and dates. However, differences can arise when the maximum value is returned from a calculation or query, or when values are converted, cast, rounded, or truncated.

- If values of types **Currency** and **Real** are multiplied, and the result is larger than the maximum possible value, in DirectQuery mode, no error is raised, and a null is returned.
- In in-memory models, no error is raised, but the maximum value is returned.

In general, because the accepted date ranges are different for Excel and SQL Server, results can be guaranteed to match only when dates are within the common date range, which is inclusive of the following dates:

- Earliest date: March 1, 1990
- Latest date: December 31, 9999

If any dates used in formulas fall outside this range, either the formula will result in an error, or the results will not match.

Floating point values supported by CEILING

EXAMPLE: `EVALUATE ROW("x", CEILING(-4.398488E+30, 1))`

The Transact-SQL equivalent of the DAX CEILING function only supports values with magnitude of 10^{19} or less. A rule of thumb is that floating point values should be able to fit into **bigint**.

Datepart functions with dates that are out of range

Results in DirectQuery mode are guaranteed to match those in in-memory models only when the date used as the argument is in the valid date range. If these conditions are not satisfied, either an error will be raised, or the formula will return different results in DirectQuery than in in-memory mode.

EXAMPLE: `MONTH(0)` or `YEAR(0)`

In DirectQuery mode, the expressions return 12 and 1899, respectively.

In in-memory models, the expressions return 1 and 1900, respectively.

EXAMPLE: `EOMONTH(0.0001, 1)`

The results of this expression will match only when the data supplied as a parameter is within the valid date range.

EXAMPLE: `EOMONTH(blank(), blank())` or `EDATE(blank(), blank())`

The results of this expression should be the same in DirectQuery mode and in-memory mode.

Truncation of time values

EXAMPLE: `SECOND(1231.04097222222)`

In DirectQuery mode, the result is truncated, following the rules of SQL Server, and the expression evaluates to 59.

In in-memory models, the results of each interim operation are rounded; therefore, the expression evaluates to 0.

The following example demonstrates how this value is calculated:

1. The fraction of the input (0.04097222222) is multiplied by 24.
2. The resulting hour value (0.9833333328) is multiplied by 60.
3. The resulting minute value is 58.9999999968.
4. The fraction of the minute value (0.9999999968) is multiplied by 60.
5. The resulting second value (59.999999808) rounds up to 60.
6. 60 is equivalent to 0.

SQL Time data type not supported

In-memory models do not support use of the new SQL **Time** data type. In DirectQuery mode, formulas that reference columns with this data type will return an error. Time data columns cannot be imported into an in-memory model.

However, sometimes the engine casts the time value to an acceptable data type, and the formula returns a result.

This behavior affects all functions that use a date column as a parameter.

Currency

In DirectQuery mode, if the result of an arithmetic operation has the type **Currency**, the value must be within the following range:

- Minimum: -922337203685477.5808
- Maximum: 922337203685477.5807

Combining currency and REAL data types

EXAMPLE: [Currency sample 1](#)

If **Currency** and **Real** types are multiplied, and the result is larger than 9223372036854774784 (0x7ffffffffffffc00), DirectQuery mode will not raise an error.

In an in-memory model, an error is raised if the absolute value of the result is larger than 922337203685477.4784.

Operation results in an out-of-range value

EXAMPLE: [Currency sample 2](#)

If operations on any two currency values result in a value that is outside the specified range, an error is raised in in-memory models, but not in DirectQuery models.

Combining currency with other data types

Division of currency values by values of other numeric types can result in different results.

Aggregation functions

Statistical functions on a table with one row return different results. Aggregation functions over empty tables also behave differently in in-memory models than they do in DirectQuery mode.

Statistical functions over a table with a single row

If the table that is used as argument contains a single row, in DirectQuery mode, statistical functions such as STDEV and VARx return null.

In an in-memory model, a formula that uses STDEV or VARx over a table with a single row returns a division by zero error.

Text functions

Because relational data stores provide different text data types than does Excel, you may see different results when searching strings or working with substrings. The length of strings also can be different.

In general, any string manipulation functions that use fixed-size columns as arguments can have different results.

Additionally, in SQL Server, some text functions support additional arguments that are not provided in Excel. If the formula requires the missing argument you can get different results or errors in the in-memory model.

Operations that return a character using LEFT, RIGHT, etc. may return the correct character but in a different case, or no results

EXAMPLE: `LEFT(["text"], 2)`

In DirectQuery mode, the case of the character that is returned is always exactly the same as the letter that is stored in the database. However, the VertiPaq engine uses a different algorithm for compression and indexing of values, to improve performance.

By default, the Latin1_General collation is used, which is case-insensitive but accent-sensitive. Therefore, if there are multiple instances of a text string in lower case, upper case, or mixed case, all instances are considered the same string, and only the first instance of the string is stored in the index. All text functions that operate on stored strings will retrieve the specified portion of the indexed form. Therefore, the example formula would return the same value for the entire column, using the first instance as the input.

This behavior also applies to other text functions, including RIGHT, MID, and so forth.

String length affects results

EXAMPLE: `SEARCH("within string", "sample target text", 1, 1)`

If you search for a string using the SEARCH function, and the target string is longer than the within string, DirectQuery mode raises an error.

In an in-memory model, the searched string is returned, but with its length truncated to the length of <within text>.

EXAMPLE: `EVALUATE ROW("X", REPLACE("CA", 3, 2, "California"))`

If the length of the replacement string is greater than the length of the original string, in DirectQuery mode, the formula returns null.

In in-memory models, the formula follows the behavior of Excel, which concatenates the source string and the replacement string, which returns CACalifornia.

Implicit TRIM in the middle of strings

EXAMPLE: `TRIM(" A sample sentence with leading white space")`

DirectQuery mode translates the DAX TRIM function to the SQL statement `LTRIM(RTRIM(<column>))`. As a result, only leading and trailing white space is removed.

In contrast, the same formula in an in-memory model removes spaces within the string, following the behavior of Excel.

Implicit RTRIM with use of LEN function

EXAMPLE: `LEN('string_column')`

Like SQL Server, DirectQuery mode automatically removes white space from the end of string columns: that is, it performs an implicit RTRIM. Therefore, formulas that use the LEN function can return different values if the string

has trailing spaces.

In-memory supports additional parameters for SUBSTITUTE

EXAMPLE: `SUBSTITUTE([Title], "Doctor", "Dr. ")`

EXAMPLE: `SUBSTITUTE([Title], "Doctor", "Dr. ", 2)`

In DirectQuery mode, you can use only the version of this function that has three (3) parameters: a reference to a column, the old text, and the new text. If you use the second formula, an error is raised.

In in-memory models, you can use an optional fourth parameter to specify the instance number of the string to replace. For example, you can replace only the second instance, etc.

Restrictions on string lengths for REPT operations

In in-memory models, the length of a string resulting from an operation using REPT must be less than 32,767 characters.

This limitation does not apply in DirectQuery mode.

Substring operations return different results depending on character type

EXAMPLE: `MID([col], 2, 5)`

If the input text is **varchar** or **nvarchar**, the result of the formula is always the same.

However, if the text is a fixed-length character and the value for `<num_chars>` is greater than the length of the target string, in DirectQuery mode, a blank is added at the end of the result string.

In an in-memory model, the result terminates at the last string character, with no padding.

Tables and columns in tabular models

10/25/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you've added tables and data into a model by using the Table Import Wizard, you can begin working with the tables by adding new columns of data, creating relationships between tables, defining calculations that extend the data, and filtering and sorting data in the tables for easier viewing.

Benefits

Tables, in tabular models, provide the framework in which columns and other metadata are defined. Tables include:

Table Definition

The table definition includes the set of columns. Columns can be imported from a data source or added manually, such as with calculated columns.

Table Metadata

Relationships, measures, roles, perspectives, and pasted data are all metadata that define objects within the context of a table.

Data

Data is populated in table columns when you first import tables by using the Table Import Wizard or by creating new data in calculated columns. When data changes at the source, or when a model is removed from memory, you must run a process operation to re-populate the data into the tables.

Working with tables and columns

In the model designer, you do not create new model tables directly. A new tab is created automatically for you whenever data is imported or copied from another data source. Each tab (in the model designer) contains one table of data, which can include the following:

- A single table or view from a relational database, or from other non-relational sources, such as an Analysis Services cube.
- A tabular set of data imported from a feed or text file.
- A combination of both relational data and tabular (HTML) data copy and pasted into the table.

When you import data, each table or view, sheet, or file of data is added as a table in the model designer. You typically add data from various sources onto separate tabs, but you can combine data in a single table by using **Paste** and **Paste Append**.

After you have added the data that you need, you can create additional relationships between the tables, look up or reference related values in other tables, or create derived values by adding new calculated columns.

If you are working with very large data sets, you may want to filter out certain data so it is not visible. You may also want to sort data in a different order. By using the model designer, you can use the filter, sort, and hide features to display, or not display, entire columns or certain data.

Add columns to a table

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to add columns to an existing table.

Add columns from the datasource

When using the Table Import Wizard to import data from a data source table, a new table is created in the model which includes all of the columns in the source table, or if you choose to filter out certain columns by using the Preview and Filter feature, only those columns and filtered data you select. You can also write a SQL Query that specifies only certain columns to import. You may, however, later determine a source table has additional columns that you want to add to the model table, or you need to add a calculated column with values derived from a DAX formula.

If, for example, when you initially imported from a data source, you used the Preview and Filter feature in the Table Import Wizard to select a limited number of columns from the source table, you later determine that you need to add another column that exists at the source table, but does not yet exist in the model table. Or, for example, a new AdjustedProfit column was added to the FactSales table at the data source, and you now want to add the same AdjustedProfit column and data to the Sales table in the model.

In these cases, you can use the Edit Table Properties dialog box to select columns from the source table and add them to the model table. The Edit Table Properties dialog box includes the table preview window. The table preview window displays the table at the source. Columns that are already included in the model table definition are already checked. Those columns that are not already included in the model table definition are not checked. You can add columns from the source to the model table definition by selecting the column and clicking OK. The table preview window in the Edit Table Properties dialog box provides the same view and features as the table preview window in the Preview and Filter page of the Table Import Wizard.

IMPORTANT

When adding a column to a table that contains two or more partitions, before adding the column to the table definition by using the Edit Table Properties dialog box, you must first use Partition Manager to add the column to all defined partitions. After you have added the column to the defined partitions, you can then add the same column to the table definition by using the Edit Table Properties dialog box.

NOTE

If you used a SQL Query to select tables and columns when you initially used the Table Import Wizard to import data, you must again use a SQL Query in the Edit Table Properties dialog box to add columns to the model table.

To add a column from the data source by using the Edit Table Properties dialog box

1. In the model designer, click on the table you want to add a column to, then click the **Table** menu, and then click **Table Properties**.
2. In the **Edit Table Properties** dialog box, in the table preview window, select the source column you want to add, and then click OK. Columns already included in the table definition will already be checked.

Add a calculated column

In a calculated column, a DAX formula is used to define a value for each row. For example, you can create a calculated column with a simple formula (=1) that adds a value of 1 to each row. Calculated columns can also have more complex formulas that calculate values based on other data in the model. Calculated columns are covered in more detail in other topics. For more information, see [Calculated Columns](#).

To create a calculated column

1. In the model designer, in Data View, select the table to which you want to add a new, blank calculated column, scroll to the right-most column, or click the **Column** menu, and then click **Add Column**.

To create a new column between two existing columns, right-click on an existing column, and then click **Insert Column**.

2. In the formula bar, type a DAX formula to add attributes for each row.

Add a blank column

You can create a named, blank column in a model table. Blank columns can be useful if you want to paste data from another source. Keep in-mind that pasted data is stored differently than imported data.

To create a named, blank column

1. In the model designer, in Data View, select the table to which you want to add a blank column, scroll to the right-most column, or click the **Column** menu, and then click **Add Column**.

To create a new column between two existing columns, right-click an existing column, and then click **Insert Column**.

2. Click on the top cell, then type a name, and then press ENTER.

[Change table, column, or row filter mappings](#)

Delete a Column

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to delete a column from a tabular model table.

Delete a Model Table Column

NOTE

Deleting a column from a model table does not delete the column from a partition query definition. If the column you are deleting is part of a partition, you must manually delete the column from the partition query definition. Failure to delete the column from the partition query definition will cause the column to be queried and data returned, but not populated to the model table, during processing operations. For more information, see [Partitions](#).

To delete a model table column

- In the model designer, in the table that contains the column you want to delete, right-click on the column, and then click **Delete**.

To delete a model table column by using the Table Properties dialog box

1. In the model designer, click on the table which contains the column you want to delete, then click the **Table** menu, and then click **Table Properties**.
2. In **Column names from**, select **Model** (*to use model table column names, if different from source*).
3. In the **Edit Table Properties** dialog box, in the table preview window, uncheck the column you want to delete, and then click **OK**.

[Add columns to a table](#)

[Partitions](#)

Change table, column, or row filter mappings

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to change table, column, or row filter mappings by using the **Edit Table Properties** dialog box in Visual Studio with Analysis Services projects.

Options in the **Edit Table Properties** dialog box are different depending on whether you originally imported data by selecting tables from a list or by using a SQL query. If you originally imported the data by selecting from a list, the **Edit Table Properties** dialog box displays the Table Preview mode. This mode displays only a subset limited to the first fifty rows of the source table. If you originally imported the data by using a SQL statement, the **Edit Table Properties** dialog box only displays a SQL statement. Using a SQL query statement, you can retrieve a subset of rows, either by designing a filter, or by manually editing the SQL statement.

If you change the source to a table that has different columns than the current table, a message is displayed warning that the columns are different. You must then select the columns that you want to put in the current table and click **Save**. You can replace the entire table by selecting the check box at the left of the table.

NOTE

If your table has more than one partition, you cannot use the Edit Table Properties dialog box to change row filter mappings. To change row filter mappings for tables with multiple partitions, use Partition Manager. For more information, see [Partitions](#).

To change table, column, or row filter mappings

1. In the model designer, click the table, then click on the **Table** menu, and then click **Table Properties**.
2. In the **Edit Table Properties** dialog box, locate the column that contains the criteria you want to filter on, and then click the down arrow at the right of the column heading.
3. In the **AutoFilter** menu, do one of the following:
 - In the list of column values, select or clear one or more values to filter by, and then click **OK**.
If the number of values is extremely large, individual items might not be shown in the list. Instead, you will see the message, "Too many items to show."
 - Click **Number Filters** or **Text Filters** (depending on the type of column), and then click one of the comparison operator commands (such as Equals), or click Custom Filter. In the **Custom Filter** dialog box, create the filter, and then click **OK**.

If you make a mistake and need to start over, click **Clear Row Filters**.

Specify Mark as Date Table for use with time-intelligence

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In order to use time-intelligence functions in DAX formulas, you must specify a date table and a unique identifier (datetime) column of the Date data type. Once a column in the date table is specified as a unique identifier, you can create relationships between columns in the date table and any fact tables.

When using time-intelligence functions, the following rules apply:

- When using DAX time-intelligence functions, never specify a datetime column from a fact table. Always create a separate date table in your model with at least one datetime column of Date data type and with unique values.
- Make sure your date table has a continuous date range.
- The datetime column in the date table should be at day granularity (without fractions of a day).
- You must specify a date table and a unique identifier column by using the **Mark the Date Table** dialog box.
- Create relationships between fact tables and columns of Date data type in the date table.

To specify a date table and unique identifier

1. In the model designer, click the date table.
2. Click the **Table** menu, then click **Date**, and then click **Mark as Date Table**
3. In the **Mark as Date Table** dialog box, in the **Date** listbox, select a column to be used as a unique identifier. This column must contain unique values and should be of Date data type. For example:

| DATE |
|----------------------|
| 7/1/2010 12:00:00 AM |
| 7/2/2010 12:00:00 AM |
| 7/3/2010 12:00:00 AM |
| 7/4/2010 12:00:00 AM |
| 7/5/2010 12:00:00 AM |

4. If necessary, create any relationships between fact tables and the date table.

Add a table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to add a table from a data source from which you have previously imported data into your model. To add a table from the same data source, you can use the existing data source connection. It is recommended you always use a single connection when importing any number of tables from a single data source.

To add a table from an existing data source

1. In Visual Studio with Analysis Services projects, click the **Model** menu, and then click **Existing Connections**.
2. On the **Existing Connections** page, select the connection to the data source that has the table you want to add, and then click **Open**.
3. On the **Select Tables and Views** page, select the table from the data source you want to add to your model.

NOTE

The **Select Tables and Views** page will not show tables that were previously imported as checked. If you select a table that was previously imported using this connection, and you did not give the table a different friendly name, a 1 will be appended to the friendly name. You do not need to re-select any tables that were previously imported by using this connection.

4. If necessary, use **Preview & Filter** to select only certain columns or apply filters to the data to be imported.
5. Click **Finish** to import the new table.

NOTE

When importing multiple tables at the same time from a single data source, any relationships between those tables at the source will automatically be created in the model. When adding a table later; however, you may need to manually create relationships in the model between newly added tables and the tables that were previously imported.

Delete a table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the model designer, you can delete tables in your model workspace database that you no longer need. Deleting a table does not affect the original source data, only the data that you imported and were working with. You cannot undo the deletion of a table.

To delete a table

- Right-click the tab at the bottom of the model designer for the table that you want to delete, and then click **Delete**.

Considerations when Deleting Tables

- When you delete a table, the entire tab that the table was on is deleted.
- If any measures were associated with that table, the definition of the measure will also be deleted.
- If you created any calculated columns using that table, columns in that table are also deleted; any calculated columns in other tables that use columns from the deleted table will display an error.

[Tables and columns](#)

Create a calculated table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A *calculated table* is a computed object, based on either a DAX query or expression, derived from all or part of other tables in the same model.

A common design problem that calculated tables can solve is surfacing a role-playing dimension in a specific context so that you can expose it as a query structure in client applications. You might recall that a role-playing dimension is simply a table surfaced in multiple contexts -- a classic example is the Date table, manifested as OrderDate, ShipDate, or DueDate, depending on the foreign key relationship. By creating a calculated table for ShipDate explicitly, you get a standalone table that is available for queries, as fully operable as any other table. Another use includes configuring a filtered rowset, a subset, or superset of columns from other existing tables. This allows you to keep the original table intact while creating variations of that table to support specific scenarios.

Using calculated tables to best advantage will require that you know at least some DAX. As you work with expressions for your table, it might help to know that a calculated table contains a single partition with a DAXSource, where the expression is a DAX expression.

There is one CalculatedTableColumn for each column returned by the expression, where the SourceColumn is the name of the column returned (similar to DataColumns on non-calculated tables).

At least one table must already exist before you can create a calculated table. If you are creating a calculated table as a standalone computed table object, you can first create a table by importing from a file data source (csv, xls, xml). The file you import from can have a single column and single value. You can then hide that table.

How to create a calculated table

1. First, verify the tabular model has a compatibility level of 1200 or higher. You can check the **Compatibility Level** property on the model in SSDT.
2. Switch to the Data View. You can't create a calculated table in Diagram View.
3. Select **Table > New calculated table**.
4. Type or paste a DAX expression (see below for some ideas).
5. Name the table.
6. Create relationships to other tables in the model. See [Create a Relationship Between Two Tables](#) if you need help with this step.
7. Reference the table in calculations or expressions in your model or use **Analyze in Excel** for ad hoc data exploration.

Replicate a role-playing dimension

In the Formula bar, enter a DAX formula that gets a copy of another table. After the calculated table is populated, give it a descriptive name and then set up a relationship that uses the foreign key specific to the role. For example, in the Adventure Works database, you might create a calculated table for Due Date and use the DueDateKey as the basis of a relationship to the fact table.

```
=DimDate
```

Summarized or filtered dataset

In the Formula bar, enter a DAX expression that filters, summarizes, or otherwise manipulates a dataset to contain the rows you want. This example groups by sales by color and currency.

```
=SUMMARIZECOLUMNS(DimProduct[Color]  
, DimCurrency[CurrencyName]  
, "Sales" , SUM(FactInternetSales[SalesAmount]))  
)
```

Superset using columns from multiple tables

In the Formula bar, enter a DAX expression that combines columns from multiple tables. In this case, query output lists product category for each currency.

```
=CROSSJOIN(DimProductCategory, DimCurrency)
```

[Understanding DAX in tabular models](#)

Rename a Table or Column

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can change the name of a table during the import process by typing a **Friendly Name** in the **Select Tables and Views** page of the **Table Import Wizard**. You can also change table and column names if you import data by specifying a query on the **Specify a SQL Query** page of the **Table Import Wizard**.

After you have added the data to the model, the name (or title) of a table appears on the table tab, at the bottom of the model designer. You can change the name of your table to give it a more appropriate name. You can also rename a column after the data has been added to the model. This option is especially important when you have imported data from multiple sources, and want to ensure that columns in different tables have names that are easy to distinguish.

To rename a table

1. In the model designer, right-click the tab that contains the table that you want to rename, and then click **Rename**.
2. Type the new name.

NOTE

You can edit other properties of a table, including the connection information and column mappings, by using the **Edit Table Properties** dialog box. However, you cannot change the name in this dialog box.

To rename a column

1. In the model designer, double-click the header of the column that you want to rename, or right-click the header and select **Rename Column** from the context menu.
2. Type the new name.

Naming Requirements for Columns and Tables

The following words and characters cannot be used in the name of a table or column:

- Leading or trailing spaces
- Control characters
- The following characters (which are not valid in the names of Analysis Services objects): ..,:^*!&%\$!+=()[]{}<>
- Analysis Services reserved keywords, including Multidimensional Expressions (MDX) and Data Mining Extensions (DMX) function names and operators.

Effect of Renaming on Existing Tables, Columns, and Calculations

Whenever you change the name of a table, you change the name of the underlying table object, which may contain multiple columns or measures. Any columns that are in the table, and any relationships that use the table, must be updated to use the new name in their definitions. This update happens automatically in most cases.

Any calculations that use the renamed table, or that use columns from the renamed table, must also be updated,

and the data derived from those calculations must be refreshed and recalculated. Depending on how many tables and calculations are affected, this can take some time to complete. Therefore, the best time to rename tables is either during the import process, or before you start to build complex relationships and calculations.

Set the Data Type of a Column

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

When you import data or paste data into a model, the model designer will automatically detect and apply data types. After you have added the data to the model, you can manually modify the data type of a column to change how data is stored. If you just want to change the format of how the data is displayed without changing the way it is stored, you can do that instead.

To change the data type or display format for a column

1. In the model designer, select the column for which you want to change the data type or display format.
2. In the column **Properties** window, do one of the following:
 - In the **Data Format** property, select a different data format.
 - In the **Data Type** property, select a different data type.

Considerations when Changing Data Types

Sometimes when you try to change the data type of a column or select a data conversion, one of the following errors might occur:

- Failed to change data type
- Failed to change column data type

These errors might occur even if the data type is available as an option in the Data Type dropdown list. This section explains the cause of these errors and how you can correct them.

Understanding Automatically Determined Data Types

When you add data to a model, the model designer checks the columns of data to see what data types each column contains. If the data in that column is consistent, it assigns the most precise data type to the column.

However, if you add data from Excel or another source that does not enforce the use of a single data type within each column, the model designer will assign a data type that accommodates all values within the column.

Therefore, if a column contains numbers of different types, such as integers, long numbers, and currency, the model designer will use a decimal data type. Alternatively, if a column mixes numbers and text, the model designer will use the text data type. The model designer does not provide a data type similar to the General data type available in Excel.

Therefore, if a column contains both numbers and text values, you will not be able to convert the column to a numeric data type.

The following data types are available in business intelligence semantic models:

- **Text**
- **Decimal Number**
- **Whole Number**
- **Currency**
- **TRUE/FALSE**

- **Date**

If you find that your data has a wrong data type, or at least a different one than you wanted, you have several options:

- You can re-import the data. To do this, open the existing connection to the data source and re-import the column. Depending on the data source type, you might be able to apply a filter during import to remove problem values.
- You can create a DAX formula in a calculated column to create a new value of the desired data type. For example, the TRUNC function can be used to change a decimal number to a whole integer, or you can combine information functions and logical functions to test and convert values.

Understanding Data Conversion

If an error occurs when you select a data conversion option, it might be that the current data type of the column does not support the selected conversion. Not all conversions are allowed for all data types. For example, you can only change a column to a Boolean data type if the current data type of the column is either a number (whole or decimal) or text. Therefore, you must choose an appropriate data type for the data in the column.

After you choose an appropriate data type, the model designer will warn you about possible changes to your data, such as loss of precision, or truncation. Click OK to accept and change your data to the new data type.

If the data type is supported, but the model designer finds values that are not supported within the new data type, you will get another error, and will need to correct the data values before proceeding.

For detailed information about the data types used in business intelligence semantic models, how they are implicitly converted, and how different data types are used in formulas, see [Data Types Supported](#).

[Data Types Supported](#)

Hide or freeze columns

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In the model designer, if there are columns that you don't want to display in a table, you can temporarily hide them. Hiding a column gives you more room on the screen to add new columns or to work with only relevant columns of data. You can hide and unhide columns from the **Column** menu in the model designer, and from the right-click menu available from each column header. To keep an area of a model visible while you scroll to another area of the model, you can lock specific columns in one area by freezing them.

IMPORTANT

The ability to hide columns is not intended to be used for data security, only to simplify and shorten the list of columns visible in the model designer or reports. To secure data, you can define security roles. Roles can limit viewable metadata and data to only those objects defined in the role. For more information, see [Roles](#).

When you hide a column, you have the option to hide the column while you are working in the model designer or in reports. If you hide all columns, the entire table appears blank in the model designer.

NOTE

If you have many columns to hide, you can create a perspective instead of hiding and unhiding columns. A perspective is a custom view of the data that makes it easier to work with subset of related data. For more information, see [Create and Manage Perspectives](#)

To hide an individual column

1. In the model designer, select the table that contains the column that you want to hide.
2. Right-click the column, then click **Hide Columns**, and then click **From Designer and Reports**, **From Reports**, or **From Designer**.

To hide multiple columns

1. In the model designer, select the table that contains the columns that you want to hide.
2. Click on the **Columns** menu, and then click **Hide and Unhide**.
3. In the **Hide and Unhide Columns** dialog box, locate each column that you want to hide, and then deselect one or both of **In Designer** and **In Reports**.
4. Click **OK**.

To freeze columns

1. In the model designer, select the table that contains the columns that you want to freeze.
2. Select one or more columns to freeze.
3. Click on the **Columns** menu, and then click **Freeze..**

NOTE

When a column(s) is frozen, it is moved to left (or front) of the table in the designer. Unfreezing the column does not move it back to its original location.

[Tables and Columns](#)

[Perspectives](#)

[Roles](#)

Calculated Columns

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Calculated columns, in tabular models, enable you to add new data to your model. Instead of pasting or importing values into the column, you create a DAX formula that defines the column's row level values. The calculated column can then be used in a report, PivotTable, or PivotChart as would any other column.

Benefits

Formulas in calculated columns are much like formulas in Excel. Unlike Excel, however, you cannot create different formulas for different rows in a table; instead, the DAX formula is automatically applied to the entire column.

When a column contains a formula, the value is computed for each row. The results are calculated for the column when you enter a valid formula. Column values are then recalculated as necessary, such as when the underlying data is refreshed.

You can create calculated columns that are based on measures and other calculated columns. For example, you might create one calculated column to extract a number from a string of text, and then use that number in another calculated column.

A calculated column is based on data that you already have in an existing table, or created by using a DAX formula. For example, you might choose to concatenate values, perform addition, extract substrings, or compare the values in other fields. To add a calculated column, you must have at least one table in your model.

This example demonstrates a simple formula in a calculated column:

```
=EOMONTH([StartDate],0)
```

This formula extracts the month from the StartDate column. It then calculates the end of the month value for each row in the table. The second parameter specifies the number of months before or after the month in StartDate; in this case, 0 means the same month. For example, if the value in the StartDate column is 6/1/2001, the value in the calculated column will be 6/30/2001.

Naming a calculated column

By default, new calculated columns are added to the right of other columns in a table, and the column is automatically assigned the default name of **CalculatedColumn1**, **CalculatedColumn2**, and so forth. You can also right click a column, and then click Insert Column to create a new column between two existing columns. You can rearrange columns within the same table by clicking and dragging, and you can rename columns after they are created; however, you should be aware of the following restrictions on changes to calculated columns:

- Each column name must be unique within a table.
- Avoid names that have already been used for measures within the same model. Although it is possible for a measure and a calculated column to have the same name, if names are not unique you can get calculation errors. To avoid accidentally invoking a measure, when referring to a column always use a fully qualified column reference.

- When you rename a calculated column, any formulas that rely on the column must be updated manually. Unless you are in manual update mode, updating the results of formulas takes place automatically. However, this operation might take some time.
- There are some characters that cannot be used within the names of columns. For more information, see "Naming Requirements" in [DAX Syntax Reference](#).

Performance of calculated columns

The formula for a calculated column can be more resource-intensive than the formula used for a measure. One reason is that the result for a calculated column is always calculated for each row in a table, whereas a measure is only calculated for the cells defined by the filter used in a report, PivotTable, or PivotChart. For example, a table with a million rows will always have a calculated column with a million results, and a corresponding effect on performance. However, a PivotTable generally filters data by applying row and column headings; therefore, a measure is calculated only for the subset of data in each cell of the PivotTable.

A formula has dependencies on the objects that are referenced in the formula, such as other columns or expressions that evaluate values. For example, a calculated column that is based on another column, or a calculation that contains an expression with a column reference, cannot be evaluated until the other column is evaluated. By default, automatic refresh is enabled in workbooks; therefore, all such dependencies can affect performance while values are updated and formulas refreshed.

To avoid performance issues when you create calculated columns, follow these guidelines:

- Rather than create a single formula that contains many complex dependencies, create the formulas in steps, with results saved to columns, so that you can validate the results and assess performance.
- Modification of data will often require that calculated columns be recalculated. You can prevent this by setting the recalculation mode to manual; however, if any values in the calculated column are incorrect the column will be grayed out until you refresh and recalculate the data.
- If you change or delete relationships between tables, formulas that use columns in those tables will become invalid.
- If you create a formula that contains a circular or self-referencing dependency, an error will occur.

Create a Calculated Column

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Calculated columns allow you to add new data to your model. Instead of pasting or importing values into the column, you create a DAX formula that defines the column's row level values. The values in each row of a calculated column are calculated and populated when you create a valid formula and then click ENTER. The calculated column can then be added to a reporting or analysis application just as would any other column of data. This article describes how to create a new calculated column by using the DAX formula bar in the model designer.

To create a new calculated column

1. In the model designer, in Data View, select the table to which you want to add a calculated column, then click the **Column** menu, and then click **Add Column**.

Add Column is highlighted over the empty rightmost column, and the cursor moves to the formula bar.

To create a new column between two existing columns, right-click an existing column, and then click **Insert Column**.

2. In the formula bar, do one of the following:

- Type an equal sign followed by a formula.
- Type an equal sign, followed by a DAX function, followed by arguments and parameters as required by the function.
- Click the function button (**fx**), then in the **Insert Function** dialog box, select a category and function, and then click **OK**. In the formula bar, type the remaining arguments and parameters as required by the function.

3. Press ENTER to accept the formula.

The entire column is populated with the formula, and a value is calculated for each row.

TIP

You can use DAX Formula AutoComplete in the middle of an existing formula with nested functions. The text immediately before the insertion point is used to display values in the drop-down list, and all of the text after the insertion point remains unchanged.

Sort Data in a Table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can sort data by text (A to Z or Z to A) and numbers (smallest to largest or largest to smallest) in one or more columns.

To sort the data in a table based on a text column

1. In the model designer, select a column of alphanumeric data, a range of cells in a column, or make sure that the active cell is in a table column that contains alphanumeric data, and then click the arrow in the header of the column that you want to filter by.
2. In the AutoFilter menu, do one of the following:
 - To sort in ascending alphanumeric order, click **Sort A to Z**.
 - To sort in descending alphanumeric order, click **Sort Z to A**.

NOTE

In some cases, data imported from another application might have leading spaces inserted before data. You must remove the leading spaces in order to correctly sort the data.

To sort the data in a table based on a numeric column

1. In the model designer, select a column of alphanumeric data, a range of cells in a column, or make sure that the active cell is in a table column that contains alphanumeric data, and then click the arrow in the header of the column that you want to filter by.
2. In the AutoFilter menu, do one of the following:
 - To sort from low numbers to high numbers, click **Sort Smallest to Largest**.
 - To sort from high numbers to low numbers, click **Sort Largest to Smallest**.

NOTE

If the results are not what you expected, the column might contain numbers stored as text and not as numbers. For example, negative numbers imported from some accounting systems, or a number entered with a leading ' (apostrophe), are stored as text.

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can apply filters when you import data to control the rows that are loaded into a table. After you have imported the data, you cannot delete individual rows. However, you can apply custom filters to control the way that rows are displayed. Rows that do not meet the filtering criteria are hidden. You can filter by one or more columns. Filters are additive, which means that each additional filter is based on the current filter and further reduces the subset of data.

NOTE

The filter preview window limits the number of different values displayed. If the limit is exceeded, a message is displayed.

To filter data based on column values

1. In the model designer, select a table, and then click the arrow in the header of the column that you want to filter by.
2. In the AutoFilter menu, do one of the following:
 - In the list of column values, select or clear one or more values to filter by, and then click **OK**.
If the number of values is extremely large, individual items might not be shown in the list. Instead, you will see the message, "Too many items to show."
 - Click **Number Filters** or **Text Filters** (depending on the type of column), and then click of the comparison operator commands (such as **Equals**), or click **Custom Filter**. In the **Custom Filter** dialog box, create the filter, and then click **OK**.

To clear a filter for a column

1. Click the arrow in the header of the column for which you want to clear a filter.
2. Click **Clear Filter from <Column Name>**.

To clear all filters for a table

1. In the model designer, select the table for which you want to clear filters.
2. Click on the **Column** menu, and then click **Clear All Filters**.

Relationships

7/16/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In tabular models, a relationship is a connection between two tables of data. The relationship establishes how the data in the two tables should be correlated. For example, a Customers table and an Orders table can be related in order to show the customer name that is associated with each order.

When using the Table Import Wizard to import from the same data source, relationships that already exist in tables (at the data source) that you choose to import will be re-created in the model. You can view relationships that were detected and re-created automatically by using the model designer in Diagram View or by using the Manage Relationships dialog box. You can also create new relationships between tables manually by using the model designer in Diagram View or by using the Create Relationship or Manage Relationships dialog box.

After relationships between tables have been defined, either automatically during import or created manually, you will be able to filter data by using related columns and look up values in related tables.

TIP

If your model contains many relationships, Diagram View can better help you better visualize and create new relationships between tables.

Benefits

A relationship is a connection between two tables of data, based on one or more columns in each table. To see why relationships are useful, imagine that you track data for customer orders in your business. You could track all the data in a single table that has a structure like the following:

| CUSTOMERID | NAME | EMAIL | DISCOUNTRATE | ORDERID | ORDERDATE | PRODUCT | QUANTITY |
|------------|----------|-----------------------------|--------------|---------|------------|--------------------|----------|
| 1 | Ashton | chris.ashton@contoso.com | .05 | 256 | 2010-01-07 | Compact Digital | 11 |
| 1 | Ashton | chris.ashton@contoso.com | .05 | 255 | 2010-01-03 | SLR Camera | 15 |
| 2 | Jaworski | michal.jaworski@contoso.com | .10 | 254 | 2010-01-03 | Budget Movie-Maker | 27 |

This approach can work, but it involves storing a lot of redundant data, such as the customer e-mail address for every order. Storage is cheap, but you have to make sure you update every row for that customer if the e-mail address changes. One solution to this problem is to split the data into multiple tables and define relationships between those tables. This is the approach used in *relational databases* like SQL Server. For example, a database that you import into a model might represent order data by using three related tables:

Customers

| [CUSTOMERID] | NAME | EMAIL |
|--------------|----------|-----------------------------|
| 1 | Ashton | chris.ashton@contoso.com |
| 2 | Jaworski | michal.jaworski@contoso.com |

CustomerDiscounts

| [CUSTOMERID] | DISCOUNTRATE |
|--------------|--------------|
| 1 | .05 |
| 2 | .10 |

Orders

| [CUSTOMERID] | ORDERID | ORDERDATE | PRODUCT | QUANTITY |
|--------------|---------|------------|--------------------|----------|
| 1 | 256 | 2010-01-07 | Compact Digital | 11 |
| 1 | 255 | 2010-01-03 | SLR Camera | 15 |
| 2 | 254 | 2010-01-03 | Budget Movie-Maker | 27 |

If you import these tables from the same database, the Table Import Wizard can detect the relationships between the tables based on the columns that are in [brackets], and can reproduce these relationships in the model designer. For more information, see [Automatic Detection and Inference of Relationships](#) in this topic. If you import tables from multiple sources, you can manually create relationships as described in [Create a Relationship Between Two Tables](#).

Columns and keys

Relationships are based on columns in each table that contain the same data. For example, the Customers and Orders tables can be related to each other because they both contain a column that stores a customer ID. In the example, the column names are the same, but this is not a requirement. One could be CustomerID and another CustomerNumber, as long as all of the rows in the Orders table contain an ID that is also stored in the Customers table.

In a relational database, there are several types of *keys*, which are typically just columns with special properties. The following four types of keys can be used in relational databases:

- *Primary key*: uniquely identifies a row in a table, such as CustomerID in the Customers table.
- *Alternate key* (or *candidate key*): a column other than the primary key that is unique. For example, an Employees table might store an employee ID and a social security number, both of which are unique.
- *Foreign key*: a column that refers to a unique column in another table, such as CustomerID in the Orders table, which refers to CustomerID in the Customers table.
- *Composite key*: a key that is composed of more than one column. Composite keys are not supported in tabular models. For more information, see "Composite Keys and Lookup Columns" in this topic.

In tabular models, the primary key or alternate key is referred to as the *related lookup column*, or just *lookup column*. If a table has both a primary and alternate key, you can use either as the lookup column. The foreign key is referred to as the *source column* or just *column*. In our example, a relationship would be defined between CustomerID in the Orders table (the column) and CustomerID (the lookup column) in the Customers table. If you

import data from a relational database, by default the model designer chooses the foreign key from one table and the corresponding primary key from the other table. However, you can use any column that has unique values for the lookup column.

Types of relationships

The relationship between Customers and Orders is a *one-to-many relationship*. Every customer can have multiple orders, but an order cannot have multiple customers. The other types of relationships are *one-to-one* and *many-to-many*. The CustomerDiscounts table, which defines a single discount rate for each customer, is in a one-to-one relationship with the Customers table. An example of a many-to-many relationship is a direct relationship between Products and Customers, in which a customer can buy many products and the same product can be bought by many customers. The model designer does not support many-to-many relationships in the user interface. For more information, see "[Many-to-Many Relationships](#)" in this topic.

The following table shows the relationships between the three tables:

| RELATIONSHIP | TYPE | LOOKUP COLUMN | COLUMN |
|---------------------------------|-------------|----------------------|------------------------------|
| Customers-
CustomerDiscounts | one-to-one | Customers.CustomerID | CustomerDiscounts.CustomerID |
| Customers-Orders | one-to-many | Customers.CustomerID | Orders.CustomerID |

Relationships and performance

After any relationship has been created, the model designer typically must recalculate any formulas that use columns from tables in the newly created relationship. Processing can take some time depending on the amount of data and the complexity of the relationships.

Requirements for relationships

The model designer has several requirements that must be followed when creating relationships:

Single Active Relationship between tables

Multiple relationships could result in ambiguous dependencies between tables. To create accurate calculations, you need a single path from one table to the next. Therefore, there can be only one active relationship between each pair of tables. For example, in AdventureWorks DW 2012, the table, DimDate, contains a column, DateKey, that is related to three different columns in the table, FactInternetSales: OrderDate, DueDate, and ShipDate. If you attempt to import these tables, the first relationship is created successfully, but you will receive the following error on successive relationships that involve the same column:

* Relationship: table[column 1]-> table[column 2] - Status: error - Reason: A relationship cannot be created between tables <table 1> and <table 2>. Only one direct or indirect relationship can exist between two tables.

If you have two tables and multiple relationships between them, then you will need to import multiple copies of the table that contains the lookup column, and create one relationship between each pair of tables.

There can be many inactive relationships between tables. The path to use between tables is specified by the reporting client at query time.

One relationship for each source column

A source column cannot participate in multiple relationships. If you have used a column as a source column in one relationship already, but want to use that column to connect to another related lookup column in a different table, you can create a copy of the column, and use that column for the new relationship.

It is easy to create a copy of a column that has the exact same values, by using a DAX formula in a calculated column. For more information, see [Create a Calculated Column](#).

Unique identifier for each table

Each table must have a single column that uniquely identifies each row in that table. This column is often referred to as the primary key.

Unique lookup columns

The data values in the lookup column must be unique. In other words, the column cannot contain duplicates. In Tabular models, nulls and empty strings are equivalent to a blank, which is a distinct data value. This means that you cannot have multiple nulls in the lookup column.

Compatible data types

The data types in the source column and lookup column must be compatible. For more information about data types, see [Data Types Supported](#).

Composite keys and lookup columns

You cannot use composite keys in a tabular model; you must always have one column that uniquely identifies each row in the table. If you try to import tables that have an existing relationship based on a composite key, the Table Import Wizard will ignore that relationship because it cannot be created in the tabular model.

If you want to create a relationship between two tables in the model designer, and there are multiple columns defining the primary and foreign keys, you must combine the values to create a single key column before creating the relationship. You can do this before you import the data, or you can do this in the model designer by creating a calculated column.

Many-to-Many relationships

Tabular models do not support many-to-many relationships, and you cannot add *junction tables* in the model designer. However, you can use DAX functions to model many-to-many relationships.

You can also try setting up a bi-directional cross filter to see if it achieves the same purpose. Sometimes the requirement of many-to-many relationship can be satisfied through cross filters that persist a filter context across multiple table relationships. See [Bi-directional cross filters for tabular models in SQL Server 2016 Analysis Services](#) for details.

Self-joins and loops

Self-joins are not permitted in tabular model tables. A self-join is a recursive relationship between a table and itself. Self-joins are often used to define parent-child hierarchies. For example, you could join an Employees table to itself to produce a hierarchy that shows the management chain at a business.

The model designer does not allow loops to be created among relationships in a model. In other words, the following set of relationships is prohibited.

Table 1, column a to Table 2, column f

Table 2, column f to Table 3, column n

Table 3, column n to Table 1, column a

If you try to create a relationship that would result in a loop being created, an error is generated.

Inference of relationships

In some cases, relationships between tables are automatically chained. For example, if you create a relationship between the first two sets of tables below, a relationship is inferred to exist between the other two tables, and a relationship is automatically established.

Products and Category -- created manually

Category and SubCategory -- created manually

Products and SubCategory -- relationship is inferred

In order for relationships to be automatically chained, the relationships must go in one direction, as shown above. If the initial relationships were between, for example, Sales and Products, and Sales and Customers, a relationship is not inferred. This is because the relationship between Products and Customers is a many-to-many relationship.

Detection of relationships when importing data

When you import from a relational data source table, the Table Import Wizard detects existing relationships in those source tables based on the source schema data. If related tables are imported, those relationships will be duplicated in the model.

Manually create relationships

While most relationships between tables in a single relational data source will be detected automatically, and created in the tabular model, there are also many instances where you must manually create relationships between model tables.

If your model contains data from multiple sources, you will likely have to manually create relationships. For example, you may import Customers, CustomerDiscounts, and Orders tables from a relational data source. Relationships existing between those tables at the source are automatically created in the model. You may then add another table from a different source, for example, you import region data from a Geography table in a Microsoft Excel workbook. You can then manually create a relationship between a column in the Customers table and a column in the Geography table.

To manually create relationships in a tabular model, you can use the model designer in Diagram View or by using the Manage Relationships dialog box. The diagram view displays tables, with relationships between them, in a graphical format. You can click a column in one table and drag the cursor to another table to easily create a relationship, in the correct order, between the tables. The Manage Relationships dialog box displays relationships between tables in a simple table format. To learn how to manually create relationships, see [Create a Relationship Between Two Tables](#).

Duplicate values and other errors

If you choose a column that cannot be used in the relationship, a red X appears next to the column. You can pause the cursor over the error icon to view a message that provides more information about the problem. Problems that can make it impossible to create a relationship between the selected columns include the following:

| PROBLEM OR MESSAGE | RESOLUTION |
|--|--|
| The relationship cannot be created because both columns selected contain duplicate values. | To create a valid relationship, at least one column of the pair that you select must contain only unique values.

You can either edit the columns to remove duplicates, or you can reverse the order of the columns so that the column that contains the unique values is used as the Related Lookup Column . |
| The column contains a null or empty value. | Data columns cannot be joined to each other on a null value. For every row, there must be a value in both of the columns that are used in a relationship. |

[Import Data](#)

Create a relationship

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

If the tables in your data source do not have existing relationships, or if you add new tables, you can use the tools in the model designer to create new relationships. For information about how relationships are used in tabular models, see [Relationships](#).

Create a relationship between two tables

To create a relationship between two tables in Diagram View (Click and drag)

1. In Visual Studio with Analysis Services projects, click the **Model** menu, then click **Model View**, and then click **Diagram View**.
2. Click (and hold) on a column within a table, then drag the cursor to a related lookup column in a related lookup table, and then release. The relationship will be created in the correct order automatically.

To create a relationship between two tables in Diagram View (Right-click)

1. In Visual Studio with Analysis Services projects, click the **Model** menu, then click **Model View**, and then click **Diagram View**.
2. Right-click a table heading or column, and then click **Create Relationship**.
3. In the **Create Relationship** dialog box, click the down arrow for **Table**, and select a table from the dropdown list.

In a "one-to-many" relationship, this table should be on the "many" side.

4. For **Column**, select the column that contains the data that is related to **Related Lookup Column**. The column is automatically selected if you right-clicked on a column to create the relationship.
5. For **Related Lookup Table**, select a table that has at least one column of data that is related to the table you just selected for **Table**.

In a "one-to-many" relationship, this table should be on the "one" side, meaning that the values in the selected column do not contain duplicates. If you attempt to create the relationship in the wrong order (one-to-many instead of many-to-one), an icon will appear next to the **Related Lookup Column** field. Reverse the order to create a valid relationship.

6. For **Related Lookup Column**, select a column that has unique values that match the values in the column you selected for **Column**.
7. Click **Create**.

To create a relationship between two tables in Data View

1. In Visual Studio with Analysis Services projects, click the **Table** menu, and then click **Create Relationships**.
2. In the **Create Relationship** dialog box, click the down arrow for **Table**, and select a table from the dropdown list.
3. In a "one-to-many" relationship, this table should be on the "many" side.
4. For **Column**, select the column that contains the data that is related to **Related Lookup Column**.

4. For **Related Lookup Table**, select a table that has at least one column of data that is related to the table you just selected for **Table**.

In a "one-to-many" relationship, this table should be on the "one" side, meaning that the values in the selected column do not contain duplicates. If you attempt to create the relationship in the wrong order (one-to-many instead of many-to-one), an icon will appear next to the **Related Lookup Column** field. Reverse the order to create a valid relationship.

5. For **Related Lookup Column**, select a column that has unique values that match the values in the column you selected for **Column**.
6. Click **Create**.

[Delete relationships](#)

[Relationships](#)

Delete relationships

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can delete existing relationships by using the model designer in Diagram View or by using the Manage Relationships dialog box. For information about how relationships are used in tabular models, see [Relationships](#).

Considerations for deleting relationships

Keep the following issues in mind when deciding whether to delete a relationship:

- There is no way to undo the deletion of a relationship. You can re-create the relationship, but this action requires a complete recalculation of formulas in the model. Therefore, always check first before deleting a relationship that is used in formulas.
- Deleting a relationship between two tables can cause errors in formulas that reference these tables.
- The Data Analysis Expression (DAX) RELATED function uses the relationships between tables to look up related values in another table. It will return different results after the relationship is deleted. For more information, see the RELATED Function (DAX).
- In addition to changing PivotTable and formula results, both the creation and deletion of relationships will cause the workbook to be recalculated, which can take some time.

Delete Relationships

To delete a relationship by using Diagram View

1. In Visual Studio with Analysis Services projects, click the **Model** menu, then point to **Model View**, and then click **Diagram View**.
2. Right-click a relationship line between two tables, and then click **Delete**.

To delete a relationship by using the Manage Relationships dialog box

1. In Visual Studio with Analysis Services projects, click the **Table** menu, and then click **Manage Relationships**.
2. In the **Manage Relationships** dialog box, select one or more relationships from the list.
To select multiple relationships, hold down CTRL while you click each relationship.
3. Click **Delete Relationship**.
4. In the **Manage Relationships** dialog box, click **Close**.

[Create a relationship](#)

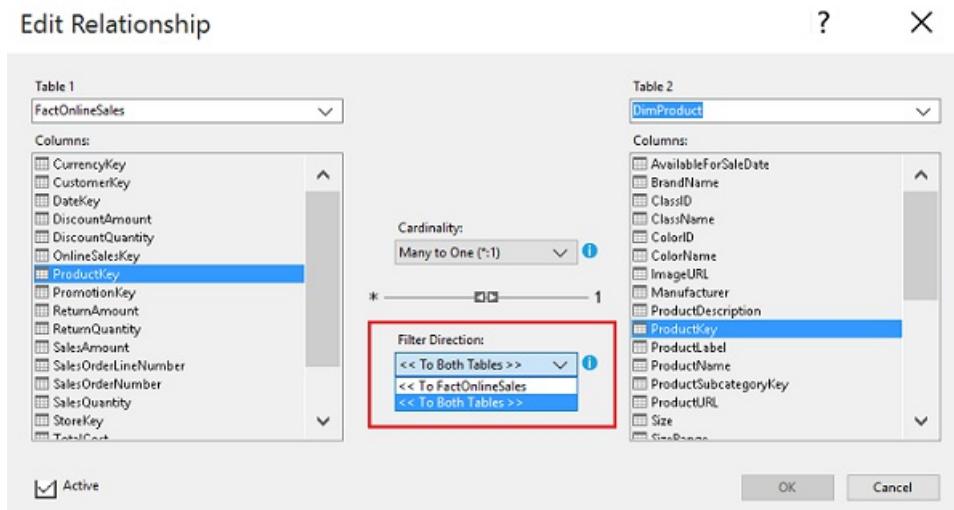

Bi-directional cross filters in tabular models

10/25/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

New in SQL Server 2016 is a built-in approach for enabling *bi-directional cross filters* in tabular models, eliminating the need for hand-crafted DAX workarounds for propagating filter context across table relationships.

Breaking the concept down into its component parts: *cross filtering* is the ability to set a filter context on a table based on values in a related table, and *bi-directional* is the transference of a filter context to second related table on the other side of a table relationship. As the name implies, you can slice in both directions of the relationship rather than just one way. Internally, two-way filtering expands filter context to query a superset of your data.

There are two types of cross filters: One-way and two-way filtering. One-way is the traditional many-to-one filter direction between fact and dimensional tables in that relationship. Two-way is a cross-filter that enables the filter context of one relationship to be used as the filter context for another table relationship, with one table common to both relationships.

Given **DimDate** and **DimProduct** with foreign key relationships to **FactOnlineSales**, a two-way cross filter is equivalent of **FactOnlineSales-to-DimDate** plus **FactOnlineSales-to-DimProduct** used simultaneously.

Bi-directional cross filters can be an easy fix to the many-to-many query design problem that has challenged tabular and Power Pivot developers in the past. If you've used the DAX workaround for many-to-many relationships in tabular or Power Pivot models, you can try applying a two-way filter to see if it produces expected results.

When creating a bi-directional cross filter, keep the following points in mind:

- Think before you enable two-way filters.

If you enable two-way filters everywhere, your data could be over-filtered in ways that you might not expect. You might also inadvertently introduce ambiguity by creating more than one potential query path. To avoid both issues, plan on using a combination of one-way and two-way filters.

- Do incremental testing to verify the impact of each filter change on your model. The Analyze in Excel feature in Visual Studio works well for incremental testing. As a best practice, periodically follow that up with tests using other reporting clients so that there are no surprises later.

NOTE

Starting in CTP 3.2, SSDT includes a default that determines whether bi-directional cross filters are attempted automatically. If you enable bi-directional filters by default, SSDT will enable two-way filtering only if the model clearly articulates one query path through a chain of table relationships.

Set the default

Single directional filters are the default. You can change the default for all new projects created in the designer, or on the model itself when the project already exists.

At the project level, the setting is evaluated when you create the project so if you change the default to bi-directional, you'll see the effects of your selection when you create the next project.

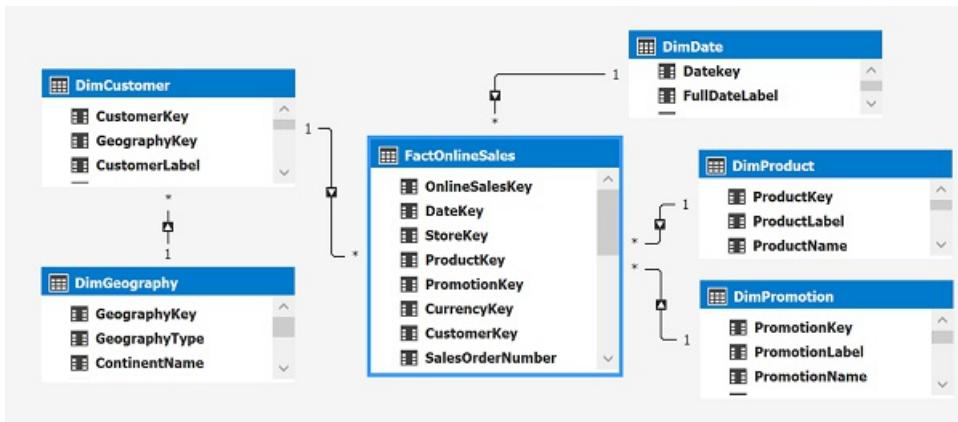

1. In SSDT, select **Tools > Options > Analysis Services Tabular Designers > New project settings**.
2. Set **Default filter direction** to either **Single direction** or **Both directions**.

Alternatively, you can change the default on the model.

1. In Solution Explorer, select **Model.bim > Properties**,
2. Set **Default filter direction** to either **Single direction** or **Both directions**.

Walkthrough an example

The best way to appreciate the value of bi-directional cross filtering is through an example. Consider the following dataset from [ContosoRetailDW](#), reflecting the cardinality and cross-filters that are created by default.

NOTE

By default, during data import, table relationships are created for you in many-to-one configurations derived from the foreign key and primary key relationships between the fact table and related dimension tables.

Notice that the filter direction is from dimension tables to the fact table -- promotions, products, dates, customer, and customer geography are all valid filters that successfully yield some aggregation of a measure, with the actual value varying based on the dimensions used.

| Manage Relationships | | | | | |
|----------------------|--------------------------------|-------------------|-----------------------|-----------------------------|--|
| | | | | | |
| Active | Table 1 | Cardinality | Filter Direction | Table 2 | |
| Yes | FactOnlineSales [PromotionKey] | Many to One (*:1) | << To FactOnlineSales | DimPromotion [PromotionKey] | |
| Yes | FactOnlineSales [ProductKey] | Many to One (*:1) | << To FactOnlineSales | DimProduct [ProductKey] | |
| Yes | FactOnlineSales [DateKey] | Many to One (*:1) | << To FactOnlineSales | DimDate [Datekey] | |
| Yes | FactOnlineSales [CustomerKey] | Many to One (*:1) | << To FactOnlineSales | DimCustomer [CustomerKey] | |
| Yes | DimCustomer [GeographyKey] | Many to One (*:1) | << To DimCustomer | DimGeography [GeographyKey] | |

For this simple star schema, testing in Excel confirms that data slices nicely when filtering flows from dimension tables on rows and columns to aggregated data provided by a **Sum of Sales** measure located in the central **FactOnlineSales** table.

| A | B | C | D | E | |
|----|------------------------|------------------|------------------|------------------|------------------|
| 1 | Sum of Sales | Column Labels | | | |
| 2 | Row Labels | Asia | Europe | North America | |
| 3 | ■ A. Datum Corporation | \$49,524,115.17 | \$56,650,738.54 | \$73,277,092.60 | \$179,451,946.31 |
| 4 | 2007 | \$23,400,450.11 | \$35,116,949.15 | \$45,844,578.11 | \$104,361,977.37 |
| 5 | 2008 | \$12,108,876.22 | \$11,163,448.13 | \$13,781,575.31 | \$37,053,899.65 |
| 6 | 2009 | \$14,014,788.85 | \$10,370,341.26 | \$13,650,939.19 | \$38,036,069.29 |
| 7 | ■ Adventure Works | \$3,648,062.21 | \$116,881,777.06 | \$149,762,018.26 | \$370,291,857.54 |
| 8 | 2007 | \$40,852,178.20 | \$60,613,375.56 | \$81,213,009.73 | \$182,678,563.48 |
| 9 | 2008 | \$29,044,034.07 | \$25,653,381.35 | \$31,781,059.77 | \$86,478,475.19 |
| 10 | 2009 | \$33,751,849.95 | \$30,615,020.16 | \$36,767,948.76 | \$101,134,818.87 |
| 11 | ■ Contoso, Ltd | \$192,442,421.53 | \$190,965,609.21 | \$239,022,265.49 | \$622,430,296.23 |
| 12 | 2007 | \$60,393,606.40 | \$78,213,463.58 | \$95,883,741.75 | \$234,490,811.73 |
| 13 | 2008 | \$64,608,599.87 | \$58,815,357.39 | \$74,135,432.63 | \$197,559,389.88 |
| 14 | 2009 | \$67,440,215.26 | \$53,936,788.25 | \$69,003,091.11 | \$190,380,094.62 |

As long as measures are pulled from the fact table and the filter context terminates at the fact table, the aggregations will be filtered correctly for this model. But what happens if you want to create measures elsewhere, such as a distinct count in the products or customer table, or an average discount in the promotion table, and have an existing filter context extend to that measure.

Let's try it out by adding a distinct count from **DimProducts** to the PivotTable. Notice the repeating values for **Count Products**. At first glance, this looks like a missing table relationship, but in our model, we can see that all the relationships are fully defined and active. In this case, the repeating values occur because there is no date filter on rows in the product table.

| A | B | | C |
|----|------------------------|--------------------|----------------|
| 1 | Row Labels | Sum of Sales | Count Products |
| 2 | ■ A. Datum Corporation | \$179,451,946.31 | 132 |
| 3 | 2005 | | 132 |
| 4 | 2006 | | 132 |
| 5 | 2007 | \$104,361,977.37 | 132 |
| 6 | 2008 | \$37,053,899.65 | 132 |
| 7 | 2009 | \$38,036,069.29 | 132 |
| 8 | 2010 | | 132 |
| 9 | 2011 | | 132 |
| 10 | ■ Adventure Works | \$370,291,857.54 | 192 |
| 11 | ■ Contoso, Ltd | \$622,430,296.23 | 710 |
| 12 | ■ Fabrikam, Inc. | \$448,626,054.69 | 267 |
| 13 | ■ Litware, Inc. | \$297,378,189.47 | 264 |
| 14 | ■ Northwind Traders | \$108,163,138.94 | 47 |

| 16 | ■ Southridge Video | \$131,026,015.56 | 192 |
| 17 | ■ Tailspin Toys | \$30,588,870.06 | 144 |
| 18 | ■ The Phone Company | \$124,810,502.38 | 152 |
| 19 | ■ Wide World Importers | \$182,147,024.42 | 173 |
| 20 | Grand Total | \$2,718,202,629.81 | 2517 |

After adding a two-way cross filter between **FactOnlineSales** and **DimProduct**, the rows in the product table are now correctly filtered by manufacturer and date.

| A | B | C |
|-------------------------|--------------------|----------------|
| Row Labels | Sum of Sales | Count Products |
| 1 A. Datum Corporation | \$179,451,946.31 | 132 |
| 2 2007 | \$104,361,977.37 | 111 |
| 3 2008 | \$37,053,899.65 | 123 |
| 4 2009 | \$38,036,069.29 | 131 |
| 5 Adventure Works | \$370,291,857.54 | 192 |
| 6 Contoso, Ltd | \$622,430,296.23 | 710 |
| 7 Fabrikam, Inc. | \$448,626,054.69 | 267 |
| 8 Litware, Inc. | \$297,378,189.47 | 264 |
| 9 Northwind Traders | \$108,163,138.94 | 47 |
| 10 Proseware, Inc. | \$223,288,734.22 | 244 |
| 11 Southridge Video | \$131,026,015.56 | 192 |
| 12 Tailspin Toys | \$30,588,870.06 | 144 |
| 13 The Phone Company | \$124,810,502.38 | 152 |
| 14 Wide World Importers | \$182,147,024.42 | 173 |
| 15 Grand Total | \$2,718,202,629.81 | 2517 |

Learn step-by-step

You can try out bi-directional cross filters by stepping through this walkthrough. To follow along, you'll need:

- SQL Server 2016 Analysis Services instance, tabular mode, latest CTP release
- [SQL Server Data Tools for Visual Studio 2015 \(SSDT\)](#), co-released with the latest CTP.
- [ContosoRetailDW](#)
- Read permissions on this data.
- Excel (for use with Analyze in Excel)

Create a project

1. Start SQL Server Data Tools for Visual Studio 2015.
2. Click **File > New > Project > Analysis Services Tabular Model**.
3. In Tabular Model Designer, set the workspace database to a SQL Server 2016 Preview Analysis Services instance in tabular server mode.
4. Verify model compatibility level is set to **SQL Server 2016 RTM (1200)** or higher.

Click **OK** to create the project.

Add Data

1. Click **Model > Import from Data Source > Microsoft SQL Server**.
2. Specify the server, database, and authentication method.
3. Choose the ContosoRetailDW database.
4. Click **Next**.
5. On table selection, ctrl-select the following tables:
 - FactOnlineSales
 - DimCustomer
 - DimDate
 - DimGeography
 - DimPromotion

You can edit the names at this point if you want them to be more readable in the model.

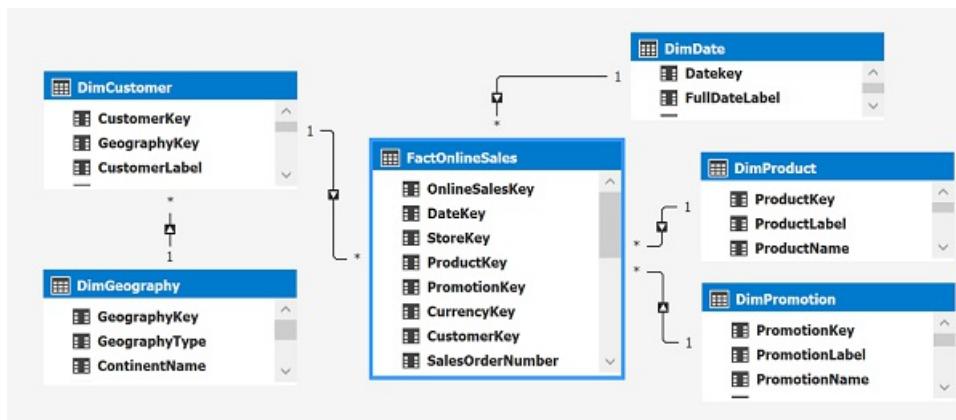

| | | | |
|-----------------------|-----------------|-----------------------|----------------|
| Server: | localhost | | |
| Database: | ContosoRetailDW | | |
| Tables and Views: | | | |
| Source Table | Schema | Friendly Name | Filter Details |
| DimChannel | dbo | | |
| DimCurrency | dbo | | |
| DimCustomer | dbo | | |
| DimDate | dbo | | |
| DimEmployee | dbo | | |
| DimEntity | dbo | | |
| DimGeography | dbo | | |
| DimMachine | dbo | | |
| DimOutage | dbo | | |
| DimProduct | dbo | | |
| DimProductCategory | dbo | | |
| DimProductSubcategory | dbo | DimProductSubcategory | |
| DimPromotion | dbo | DimPromotion | |
| DimSalesTerritory | dbo | | |
| DimScenario | dbo | | |
| DimStore | dbo | | |
| FactExchangeRate | dbo | | |
| FactInventory | dbo | | |
| FactITMachine | dbo | | |
| FactITSales | dbo | | |
| FactOnlineSales | dbo | | |
| FactSales | dbo | | |

6. Import the data.

If you get errors, confirm that the account used to connect to the database has a SQL Server login with read permissions on the Contoso data warehouse. On a remote connection, you might also want to check port configuration in the firewall for SQL Server.

Review default table relationships

Switch to diagram view: **Model > Model View > Diagram View**. Cardinality and active relationships are indicated visually. All of the relationships are one-to-many between any two related tables.

Alternatively, click **Table > Manage Relationships** to view the same information in a table layout.

| Manage Relationships | | | | |
|----------------------|--------------------------------|-------------------|-----------------------|-----------------------------|
| Active | Table 1 | Cardinality | Filter Direction | Table 2 |
| Yes | FactOnlineSales [PromotionKey] | Many to One (*:1) | << To FactOnlineSales | DimPromotion [PromotionKey] |
| Yes | FactOnlineSales [ProductKey] | Many to One (*:1) | << To FactOnlineSales | DimProduct [ProductKey] |
| Yes | FactOnlineSales [DateKey] | Many to One (*:1) | << To FactOnlineSales | DimDate [Datekey] |
| Yes | FactOnlineSales [CustomerKey] | Many to One (*:1) | << To FactOnlineSales | DimCustomer [CustomerKey] |
| Yes | DimCustomer [GeographyKey] | Many to One (*:1) | << To DimCustomer | DimGeography [GeographyKey] |

Create measures

You'll need an aggregation to sum sale amounts by different facets of dimensional data. In **DimProduct**, you can create a measure that counts products, and then use it in an analysis of product merchandising that shows a count of how many products participated in sales for a given year, a given region, or customer type.

1. Click **Model > Model View > Diagram View**.

2. Click **FactOnlineSales**.

3. Select the **SalesAmount** column.
4. Click **Column > AutoSum > Sum** to create a measure for sales.
5. Click **DimProduct**.
6. Select the **ProductKeycolumn**.
7. Click **Column > AutoSum > DistinctCount** to create a measure for unique products.

Analyze in Excel

1. Click **Model > Analyze in Excel** to bring all the data together in a PivotTable.
2. Select the two measures you just created from the field list.
3. Select **Products > Manufacturer**.
4. Select **Date > Calendar Year**.

Notice that sales are broken out by year and manufacturer as expected. This is because the default filter context between **FactOnlineSales**, **DimProduct**, and **DimDate** works correctly for measures on the 'many' side of the relationship.

At the same time, you can see that product count is not picking up on the same filter context as sales. While product counts are correctly filtered by manufacturer (both manufacturer and product counts are in the same table), the date filter is not propagated to product count.

Change the cross-filter

1. Back in the model, select **Table > Manage Relationships**.
2. Edit the relationship between **FactOnlineSales** and **DimProduct**.
Change the filter direction to both tables.
3. Save the settings.
4. In the workbook, click **Refresh** to re-read the model.

You should now see that both product counts and sales are filtered by the same filter context, one that includes not only manufacturers from **DimProducts** but also calendar year from **DimDate**.

Next steps

Understanding when and how a bi-directional cross filter can be a matter of trial and error to see how it works in your scenario. At times, you'll find that the built-in behaviors are not sufficient and will need to fall back on DAX computations to get the job done. In the **See Also** section, you'll find several links to additional resources on this subject.

In practical terms, cross-filtering can enable forms of data exploration typically delivered only through a many-to-many construction. Having said that, it's important to recognize that bi-directional cross-filtering is not a many-to-many construct. An actual many-to-many table configuration remains unsupported in the designer for tabular models in this release.

Calculations in tabular models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you have imported data into your model, you can add calculations to aggregate, filter, extend, combine, and secure that data. Tabular models use Data Analysis Expressions (DAX), a formula language for creating custom calculations. In tabular models, the calculations you create by using DAX formulas are used in *Calculated Columns*, *Measures*, and *Row Filters*.

In this section

| TOPIC | DESCRIPTION |
|---|---|
| Understanding DAX in Tabular Models | Describes the Data Analysis Expressions (DAX) formula language used to create calculations for calculated columns, measures, and row filters in tabular models. |
| DAX formula compatibility in DirectQuery mode | Describes the differences, lists the functions that are not supported in DirectQuery mode, and lists the functions that are supported but could return different results. |
| Data Analysis Expressions (DAX) Reference | This section provides detailed descriptions of DAX syntax, operators, and functions. |

NOTE

Step-by-step tasks for creating calculations are not provided in this section. Because calculations are specified in calculated columns, measures, and row filters (in roles), instructions on where to create DAX formulas are provided in tasks related to those features. For more information, see [Create a Calculated Column](#), [Create and Manage Measures](#), and [Create and Manage Roles](#).

NOTE

While DAX can also be used to query a tabular model, topics in this section focus specifically on using DAX formulas to create calculations.

DAX in tabular models

10/22/2019 • 30 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Data Analysis Expressions (DAX) is a formula language used to create custom calculations in Analysis Services, Power BI Desktop, and Power Pivot in Excel. DAX formulas include functions, operators, and values to perform advanced calculations on data in tables and columns.

While DAX is used in Analysis Services, Power BI Desktop, and Power Pivot in Excel, this topic applies more to Analysis Services tabular model projects authored in Visual Studio.

DAX formulas in calculated columns, measures, and row filters

For tabular models, DAX formulas are used in calculated columns, measures, and row filters.

Calculated columns

A calculated column is a column that you add to an existing table (in the model designer) and then create a DAX formula that defines the column's values.

NOTE

Calculated columns are not supported for models that retrieve data from a relational data source using DirectQuery mode.

When a calculated column contains a valid DAX formula, values are calculated for each row as soon as the formula is entered. Values are then stored in the database. For example, in a Date table, when the formula `= [Calendar Year] & " Q" & [Calendar Quarter]` is entered into the formula bar, a value for each row in the table is calculated by taking values from the Calendar Year column (in the same Date table), adding a space and the capital letter Q, and then adding the values from the Calendar Quarter column (in the same Date table). The result for each row in the calculated column is calculated immediately and appears, for example, as **2010 Q1**. Column values are only recalculated if the data is re-processed.

For more information, see [Calculated Columns](#).

Measures

Measures are dynamic formulas where the results change depending on context. Measures are used in reporting formats that support combining and filtering model data by using multiple attributes such as a Power BI report or Excel PivotTable or PivotChart. Measures are defined by the model author by using the measure grid (and formula bar) in the model designer in Visual Studio.

A formula in a measure can use standard aggregation functions automatically created by using the Autosum feature, such as COUNT or SUM, or you can define your own formula by using DAX. When you define a formula for a measure in the formula bar, a Tooltip feature shows a preview of what the results would be for the total in the current context, but otherwise the results are not immediately output anywhere. Other measure details also appear in the **Properties** pane.

The reason you cannot see the (filtered) results of the calculation immediately is because the result of a measure cannot be determined without context. To evaluate a measure requires a reporting client application that can provide the context needed to retrieve the data relevant to each cell and then evaluate the expression for each cell. That client might be an Excel PivotTable or PivotChart, a Power BI report, or an MDX query. Regardless of the reporting client, a separate query is run for each cell in the results. That is to say, each combination of row and

column headers in a PivotTable, or each selection of slicers and filters in a Power BI report, generates a different subset of data over which the measure is calculated. For example, in a measure with the formula,

`Total Sales:=SUM([Sales Amount])`, when a user places the TotalSales measure in the Values window in a

PivotTable, and then places the DimProductCategory column from a DimProduct table into the Filters window, the sum of Sales Amount is calculated and displayed for each product category.

Unlike calculated columns and row filters, the syntax for a measure includes the measure's name preceding the formula. In the example just provided, the name **Total Sales:** appears preceding the formula. After you have created a measure, the name and its definition appear in the reporting client application Field List and depending on perspectives and roles is available to all users of the model.

For more information, see [Measures](#).

Row filters

Row filters define which rows in a table are visible to members of a particular role. Row filters can be created for each table in a model by using DAX formulas. Row filters are created for a particular role by using Role Manager in Visual Studio. Row filters can also be defined for a deployed model by using Role Properties in SQL Server Management Studio (SSMS).

In a row filter, a DAX formula, which must evaluate to a Boolean TRUE/FALSE condition, defines which rows can be returned by the results of a query by members of that particular role. Rows not included in the DAX formula cannot be returned. For example, for members of the Sales role, the Customers table with the following DAX formula, `=Customers[Country] = "USA"`, members of the Sales role will only be able to view data for customers in the USA, and aggregates, such as SUM are returned only for customers in the USA.

When you define a row filter by using DAX formula, you are creating an allowed row set. This does not deny access to other rows; rather, they are simply not returned as part of the allowed row set. Other roles can allow access to the rows excluded by the DAX formula. If a user is a member of another role, and that role's row filters allow access to that particular row set, the user can view data for that row.

Row filters apply to the specified rows as well as related rows. When a table has multiple relationships, filters apply security for the relationship that is active. Row filters will be intersected with other row filters defined for related tables.

For more information, see [Roles](#).

DAX data types

You can import data into a model from many different data sources that might support different data types. When you import data into a model, the data is converted to one of the tabular model data types. When the model data is used in a calculation, the data is then converted to a DAX data type for the duration and output of the calculation. When you create a DAX formula, the terms used in the formula will automatically determine the value data type returned.

Tabular models, and DAX, support the following data types:

| DATA TYPE IN MODEL | DATA TYPE IN DAX | DESCRIPTION |
|--------------------|--|---|
| Whole Number | A 64 bit (eight-bytes) integer value ^{1, 2} | Numbers that have no decimal places. Integers can be positive or negative numbers, but must be whole numbers between -9,223,372,036,854,775,808 (-2^63) and 9,223,372,036,854,775,807 (2^63-1). |

| DATA TYPE IN MODEL | DATA TYPE IN DAX | DESCRIPTION |
|--------------------|--|---|
| Decimal Number | A 64 bit (eight-bytes) real number ^{1, 2} | <p>Real numbers are numbers that can have decimal places. Real numbers cover a wide range of values:</p> <p>Negative values from -1.79E +308 through -2.23E -308</p> <p>Zero</p> <p>Positive values from 2.23E -308 through 1.79E + 308</p> <p>However, the number of significant digits is limited to 17 decimal digits.</p> |
| Boolean | Boolean | Either a True or False value. |
| Text | String | A Unicode character data string. Can be strings, numbers or dates represented in a text format. |
| Date | Date/time | <p>Dates and times in an accepted date-time representation.</p> <p>Valid dates are all dates after March 1, 1900.</p> |
| Currency | Currency | Currency data type allows values between -922,337,203,685,477.5808 to 922,337,203,685,477.5807 with four decimal digits of fixed precision. |
| N/A | Blank | A blank is a data type in DAX that represents and replaces SQL nulls. You can create a blank by using the BLANK function, and test for blanks by using the logical function, ISBLANK. |

Tabular models also include the Table data type as the input or output to many DAX functions. For example, the FILTER function takes a table as input and outputs another table that contains only the rows that meet the filter conditions. By combining table functions with aggregation functions, you can perform complex calculations over dynamically defined data sets.

While data types are typically automatically set, it is important to understand data types and how they apply, in-particular, to DAX formulas. Errors in formulas or unexpected results, for example, are often caused by using a particular operator that cannot be used with a data type specified in an argument. For example, the formula, `= 1 & 2`, returns a string result of 12. The formula, `= "1" + "2"`, however, returns an integer result of 3.

For detailed information about data types in tabular models and explicit and implicit conversions of data types in DAX, see [Data Types Supported](#).

DAX operators

The DAX language uses four different types of calculation operators in formulas:

- Comparison operators to compare values and return a logical TRUE\FALSE value.

- Arithmetic operators to perform arithmetic calculations that return numeric values.
- Text concatenation operators to join two or more text strings.
- Logical operators that combine two or more expressions to return a single result.

For detailed information about operators used in DAX formulas, see [DAX Operator Reference](#).

DAX formulas

DAX formulas are essential for creating calculations in calculated columns and measures, and securing your data by using row level filters. To create formulas for calculated columns and measures, you will use the formula bar along the top of the model designer window or the DAX Editor. To create formulas for row filters, you will use the Role Manager dialog box. Information in this section is meant to get you started with understanding the basics of DAX formulas.

Formula basics

DAX enables tabular model authors to define custom calculations in both model tables, as part of calculated columns, and as measures associated with tables, but not appearing directly in them. DAX also enables model authors to secure data, by creating calculations that return a Boolean value defining which rows in a particular or related table can be queried by member users of the associated role.

DAX formulas can be very simple or quite complex. The following table shows some examples of simple formulas that could be used in a calculated column.

| Formula | Description |
|------------------------|---|
| =TODAY() | Inserts today's date in every row of the column. |
| =3 | Inserts the value 3 in every row of the column. |
| =[Column1] + [Column2] | Adds the values in the same row of [Column1] and [Column2] and puts the results in the calculated column of the same row. |

Whether the formula you create is simple or complex, you can use the following steps when building a formula:

1. Each formula must begin with an equal sign.
2. You can either type or select a function name, or type an expression.
3. Begin to type the first few letters of the function or name you want, and AutoComplete displays a list of available functions, tables, and columns. Press TAB to add an item from the AutoComplete list to the formula.

You can also click the **Fx** button to display a list of available functions. To select a function from the dropdown list, use the arrow keys to highlight the item, and click **OK** to add the function to the formula.

4. Supply the arguments to the function by selecting them from a dropdown list of possible tables and columns, or by typing in values.
5. Check for syntax errors: ensure that all parentheses are closed and columns, tables and values are referenced correctly.
6. Press ENTER to accept the formula.

NOTE

In a calculated column, as soon as you enter the formula and the formula is validated, the column is populated with values. In a measure, pressing ENTER saves the measure definition in the measure grid with the table. If a formula is invalid, an error will be displayed.

In this example, we will look at a more complex formula in a measure named Days in Current Quarter:

```
Days in Current Quarter:=COUNTROWS( DATESBETWEEN( 'Date'[Date], STARTOFQUARTER( LASTDATE('Date'[Date])),  
ENDOFQUARTER('Date'[Date])))
```

This measure is used to create a comparison ratio between an incomplete period and the previous period. The formula must take into account the proportion of the period that has elapsed, and compare it to the same proportion in the previous period. In this case, [Days Current Quarter to Date]/[Days in Current Quarter] gives the proportion elapsed in the current period.

This formula contains the following elements:

| FORMULA ELEMENT | DESCRIPTION |
|---------------------------|--|
| Days in Current Quarter:= | The name of the measure. |
| = | The equals sign (=) begins the formula. |
| COUNTROWS | The COUNTROWS function counts the number of rows in the Date table |
| () | Open and closing parenthesis specifies arguments. |
| DATESBETWEEN | The DATESBETWEEN function returns the dates between the last date for each value in the Date column in the Date table. |
| 'Date' | Specifies the Date table. Tables are in single quotes. |
| [Date] | Specifies the Date column in the Date table. Columns are in brackets. |
| , | |
| STARTOFQUARTER | The STARTOFQUARTER function returns the date of the start of the quarter. |
| LASTDATE | The LASTDATE function returns the last date of the quarter. |
| 'Date' | Specifies the Date table. |
| [Date] | Specifies the Date column in the Date table. |
| , | |
| ENDOFQUARTER | The ENDOFQUARTER function |

| FORMULA ELEMENT | DESCRIPTION |
|-----------------|--|
| 'Date' | Specifies the Date table. |
| [Date] | Specifies the Date column in the Date table. |

Using formula AutoComplete

Both the formula bar in the model designer and the formula Row Filters window in the Role Manager dialog box provide an AutoComplete feature. AutoComplete helps you enter a valid formula syntax by providing you with options for each element in the formula.

- You can use formula AutoComplete in the middle of an existing formula with nested functions. The text immediately before the insertion point is used to display values in the drop-down list, and all of the text after the insertion point remains unchanged.
- AutoComplete does not add the closing parenthesis of functions or automatically match parentheses. You must make sure that each function is syntactically correct or you cannot save or use the formula.

Using multiple functions in a formula

You can nest functions, meaning that you use the results from one function as an argument of another function. You can nest up to 64 levels of functions in calculated columns. However, nesting can make it difficult to create or troubleshoot formulas.

Many functions are designed to be used solely as nested functions. These functions return a table, which cannot be directly saved as a result; it must be provided as input to a table function. For example, the functions SUMX, AVERAGEX, and MINX all require a table as the first argument.

NOTE

Some limits are applied within measures on nesting of functions to ensure that performance is not affected by the many calculations required by dependencies among columns.

DAX functions

This section provides an overview of the *types* of functions supported in DAX. For more detailed information, see [DAX Function Reference](#).

DAX provides a variety of functions you can use perform calculations using dates and times, create conditional values, work with strings, perform lookups based on relationships, and the ability to iterate over a table to perform recursive calculations. If you are familiar with Excel formulas, many of these functions will appear very similar; however, DAX formulas are different in the following important ways:

- A DAX function always references a complete column or a table. If you want to use only particular values from a table or column, you can add filters to the formula.
- If you need to customize calculations on a row-by-row basis, DAX provides functions that let you use the current row value or a related value as a kind of parameter, to perform calculations that vary by context. To understand how these functions work, see [Context in DAX Formulas](#) later in this topic.
- DAX includes many functions that return a table, rather than a value. The table is not displayed in a reporting client, but is used to provide input to other functions. For example, you can retrieve a table and then count the distinct values in it, or calculate dynamic sums across filtered tables or columns.
- DAX functions include a variety of *time-intelligence* functions. These functions let you define or select date ranges, and perform dynamic calculations based on these dates or range. For example, you can compare sums across parallel periods.

Date and time functions

The date and time functions in DAX are similar to date and time functions in Microsoft Excel. However, DAX functions are based on the **datetime** data types used by Microsoft SQL Server. For more information, see [Date and Time Functions \(DAX\)](#).

Filter functions

The filter functions in DAX return specific data types, look up values in related tables, and filter by related values. The lookup functions work by using tables and relationships, like a database. The filtering functions let you manipulate data context to create dynamic calculations. For more information, see [Filter Functions \(DAX\)](#).

Information functions

An information function looks at the cell or row that is provided as an argument and tells you whether the value matches the expected type. For example, the ISERROR function returns TRUE if the value that you reference contains an error. For more information, see [Information Functions \(DAX\)](#).

Logical functions

Logical functions act upon an expression to return information about the values in the expression. For example, the TRUE function lets you know whether an expression that you are evaluating returns a TRUE value. For more information, see [Logical Functions \(DAX\)](#).

Mathematical and trigonometric functions

The mathematical functions in DAX are very similar to the Excel mathematical and trigonometric functions. Some minor differences exist in the numeric data types used by DAX functions. For more information, see [Math and Trig Functions \(DAX\)](#).

Other functions

These functions perform unique actions that cannot be defined by any of the categories most other functions belong to. For more information, see [Other Functions \(DAX\)](#).

Statistical functions

DAX provides statistical functions that perform aggregations. In addition to creating sums and averages, or finding the minimum and maximum values, in DAX you can also filter a column before aggregating or create aggregations based on related tables. For more information, see [Statistical Functions \(DAX\)](#).

Text functions

The text functions in DAX are very similar to their counterparts in Excel. You can return part of a string, search for text within a string, or concatenate string values. DAX also provides functions for controlling the formats for dates, times, and numbers. For more information, see [Text Functions \(DAX\)](#).

Time-intelligence functions

The time-intelligence functions provided in DAX let you create calculations that use built-in knowledge about calendars and dates. By using time and date ranges in combination with aggregations or calculations, you can build meaningful comparisons across comparable time periods for sales, inventory, and so on. For more information, see [Time-intelligence Functions \(DAX\)](#).

Table-valued functions

There are DAX functions that output tables, take tables as input, or do both. Because a table can have a single column, table-valued functions also take single columns as inputs. Understanding how to use these table-valued functions is important for fully utilizing DAX formulas. DAX includes the following types of table-valued functions:

Filter functions - Return a column, table, or values related to the current row.

Aggregation functions - Aggregate any expression over the rows of a table.

Time-intelligence functions - Return a table of dates, or use a table of dates to calculate an aggregation.

Context in DAX formulas

Context is an important concept to understand when creating formulas using DAX. Context is what enables you to perform dynamic analysis, as the results of a formula change to reflect the current row or cell selection and also any related data. Understanding context and using context effectively are critical for building high-performing, dynamic analyses, and for troubleshooting problems in formulas.

Formulas in tabular models can be evaluated in a different context, depending on other design elements:

- Filters applied in a PivotTable or report
- Filters defined within a formula
- Relationships specified by using special functions within a formula

There are different types of context: *row context*, *query context*, and *filter context*.

Row context

Row context can be thought of as "the current row". If you create a formula in a calculated column, the row context for that formula includes the values from all columns in the current row. If the table is related to another table, the content also includes all the values from the other table that are related to the current row.

For example, suppose you create a calculated column, `=[Freight] + [Tax]`, that adds together values from two columns, Freight and Tax, from the same table. This formula automatically gets only the values from the current row in the specified columns.

Row context also follows any relationships that have been defined between tables, including relationships defined within a calculated column by using DAX formulas, to determine which rows in related tables are associated with the current row.

For example, the following formula uses the RELATED function to fetch a tax value from a related table, based on the region that the order was shipped to. The tax value is determined by using the value for region in the current table, looking up the region in the related table, and then getting the tax rate for that region from the related table.

```
= [Freight] + RELATED('Region'[TaxRate])
```

This formula gets the tax rate for the current region from the Region table and adds it to the value of the Freight column. In DAX formulas, you do not need to know or specify the specific relationship that connects the tables.

Multiple row context

DAX includes functions that iterate calculations over a table. These functions can have multiple current rows, each with its own row context. In essence, these functions let you create formulas that perform operations recursively over an inner and outer loop.

For example, suppose your model contains a **Products** table and a **Sales** table. Users might want to go through the entire sales table, which is full of transactions involving multiple products, and find the largest quantity ordered for each product in any one transaction.

With DAX you can build a single formula that returns the correct value, and the results are automatically updated any time a user adds data to the tables.

```
=MAXX(FILTER(Sales,[ProdKey]=EARLIER([ProdKey])),Sales[OrderQty])
```

For a detailed walkthrough of this formula, see the [EARLIER Function \(DAX\)](#).

To summarize, the EARLIER function stores the row context from the operation that preceded the current

operation. At all times, the function stores in memory two sets of context: one set of context represents the current row for the inner loop of the formula, and another set of context represents the current row for the outer loop of the formula. DAX automatically feeds values between the two loops so that you can create complex aggregates.

Query context

Query context refers to the subset of data that is implicitly retrieved for a formula. When a user places a measure or other value field into a PivotTable or into a report based on a tabular model, the engine examines the row and column headers, Slicers, and report filters to determine the context. Then, the necessary queries are run against the data source to get the correct subset of data, make the calculations defined by the formula, and then populate each cell in the PivotTable or report. The set of data that is retrieved is the query context for each cell.

WARNING

For a model in DirectQuery mode, the context is evaluated, and then the set operations to retrieve the correct subset of data and calculate the results are translated to SQL statements. Those statements are then directly run against the relational data store. Therefore, although the method of getting the data and calculating the results is different, the context itself does not change.

Because context changes depending on where you place the formula, the results of the formula can also change.

For example, suppose you create a formula that sums the values in the **Profit** column of the **Sales** table:

=SUM('Sales'[Profit]). If you use this formula in a calculated column within the **Sales** table, the results for the formula will be the same for the entire table, because the query context for the formula is always the entire data set of the **Sales** table. Results will have profit for all regions, all products, all years, and so on.

However, users typically don't want to see the same result hundreds of times, but instead want to get the profit for a particular year, a particular country, a particular product, or some combination of these, and then get a grand total.

In a PivotTable, context can be changed by adding or removing column and row headers and by adding or removing Slicers. Whenever users add column or row headings to the PivotTable, they change the query context in which the measure is evaluated. Slicing and filtering operations also affect context. Therefore, the same formula, used in a measure, is evaluated in a different *query context* for each cell.

Filter context

Filter context is the set of values allowed in each column, or in the values retrieved from a related table. Filters can be applied to the column in the designer, or in the presentation layer (reports and PivotTables). Filters can also be defined explicitly by filter expressions within the formula.

Filter context is added when you specify filter constraints on the set of values allowed in a column or table, by using arguments to a formula. Filter context applies on top of other contexts, such as row context or query context.

In tabular models, there are many ways to create filter context. Within the context of clients that can consume the model, such as Power BI reports, users can create filters on the fly by adding slicers or report filters on the row and column headings. You can also specify filter expressions directly within the formula, to specify related values, to filter tables that are used as inputs, or to dynamically get context for the values that are used in calculations. You can also completely clear or selectively clear the filters on particular columns. This is very useful when creating formulas that calculate grand totals.

For more information about how to create filters within formulas, see the [FILTER Function \(DAX\)](#).

For an example of how filters can be cleared to create grand totals, see the [ALL Function \(DAX\)](#).

For examples of how to selectively clear and apply filters within formulas, see the [ALLEXCEPT Function \(DAX\)](#).

Determining context in formulas

When you create a DAX formula, the formula is first tested for valid syntax, and then tested to make sure the

names of the columns and tables included in the formula can be found in the current context. If any column or table specified by the formula cannot be found, an error is returned.

Context during validation (and recalculation operations) is determined as described in the preceding sections, by using the available tables in the model, any relationships between the tables, and any filters that have been applied.

For example, if you have just imported some data into a new table and it is not related to any other tables (and you have not applied any filters), the *current context* is the entire set of columns in the table. If the table is linked by relationships to other tables, the current context includes the related tables. If you add a column from the table to a report that has Slicers and maybe some report filters, the context for the formula is the subset of data in each cell of the report.

Context is a powerful concept that can also make it difficult to troubleshoot formulas. We recommend that you begin with simple formulas and relationships to see how context works. The following section provides some examples of how formulas use different types of context to dynamically return results.

Examples of context in formulas

1. The [RELATED Function \(DAX\)](#) function expands the context of the current row to include values in a related column. This lets you perform lookups. The example in this topic illustrates the interaction of filtering and row context.
2. The [FILTER Function \(DAX\)](#) function lets you specify the rows to include in the current context. The examples in this topic also illustrate how to embed filters within other functions that perform aggregates.
3. The [ALL Function \(DAX\)](#) function sets context within a formula. You can use it to override filters that are applied as result of query context.
4. The [ALLEXCEPT Function \(DAX\)](#) function lets you remove all filters except one that you specify. Both topics include examples that walk you through building formulas and understanding complex contexts.
5. The [EARLIER Function \(DAX\)](#) and [EARLIEST Function \(DAX\)](#) functions let you loop through tables by performing calculations, while referencing a value from an inner loop. If you are familiar with the concept of recursion and with inner and outer loops, you will appreciate the power that the EARLIER and EARLIEST functions provide. If you are new to these concepts, you should follow the steps in the example carefully to see how the inner and outer contexts are used in calculations.

Formulas and the tabular model

The model designer in Visual Studio is an area where you can work with multiple tables of data and connect the tables in a tabular model. Within this model, tables are joined by relationships on columns with common values (keys). The tabular model lets you link values to columns in other tables and create more interesting calculations. Just as in a relational database, you can connect many levels of related tables and use columns from any of the tables in the results.

For example, you can link a sales table, a products table, and a product categories table, and users can use various combinations of the columns in PivotTables and reports. Related fields can be used to filter connected tables, or to create calculations over subsets. (If you are not familiar with relational database and working with tables and joins, see [Relationships](#).)

Tabular models support multiple relationships among tables. To avoid confusion or wrong results, only one relationship at a time is designated as the active relationship, but you can change the active relationship as necessary to traverse different connections in the data in calculations. The [USERELATIONSHIP Function \(DAX\)](#) can be used to specify one or more relationships to be used in a specific calculation.

In a tabular model, you should observe these formula design rules:

- When tables are connected by a relationship, you must ensure that the two columns used as keys have

values that match. Referential integrity is not enforced, however; therefore it is possible to have non-matching values in a key column and still create a relationship. If this happens, you should be aware that blank values or non-matching values might affect the results of formulas.

- When you link tables in your model by using relationships, you enlarge the scope, or *context*, in which your formulas are evaluated. Changes in context resulting from the addition of new tables, new relationships, or from changes in the active relationship can cause your results to change in ways that you might not anticipate. For more information, see [Context in DAX Formulas](#) earlier in this topic.

Working with tables and columns

Tables in tabular models look like Excel tables, but are different in the way they work with data and with formulas:

- Formulas work only with tables and columns, not with individual cells, range references, or arrays.
- Formulas can use relationships to get values from related tables. The values that are retrieved are always related to the current row value.
- You cannot have irregular or "ragged" data like you can in an Excel worksheet. Each row in a table must contain the same number of columns. However, you can have empty values in some columns. Excel data tables and tabular model data tables are not interchangeable.
- Because a data type is set for each column, each value in that column must be of the same type.

Referring to tables and columns in formulas

You can refer to any table and column by using its name. For example, the following formula illustrates how to refer to columns from two tables by using the *fully qualified* name:

```
=SUM('New Sales'[Amount]) + SUM('Past Sales'[Amount])
```

When a formula is evaluated, the model designer first checks for general syntax, and then checks the names of columns and tables that you provide against possible columns and tables in the current context. If the name is ambiguous or if the column or table cannot be found, you will get an error on your formula (an #ERROR string instead of a data value in cells where the error occurs). For more information about naming requirements for tables, columns, and other objects, see "Naming Requirements" in [DAX Syntax Reference](#).

Table relationships

By creating relationships between tables, you gain the ability to look up data in another table and use related values to perform complex calculations. For example, you can use a calculated column to look up all the shipping records related to the current reseller, and then sum the shipping costs for each. In many cases, however, a relationship might not be necessary. You can use the LOOKUPVALUE function in a formula to return the value in *result_columnName* for the row that meets criteria specified in the *search_column* and *search_value* parameters.

Many DAX functions require that a relationship exist between the tables, or among multiple tables, in order to locate the columns that you have referenced and return results that make sense. Other functions will attempt to identify the relationship; however, for best results you should always create a relationship where possible. For more information, see [Formulas and the Tabular Model](#) earlier in this topic.

Updating the results of formulas (process)

Data process and *recalculation* are two separate but related operations. You should thoroughly understand these concepts when designing a model that contains complex formulas, large amounts of data, or data that is obtained from external data sources.

Processing data is the process of updating the data in a model with new data from an external data source.

Recalculation is the process of updating the results of formulas to reflect any changes to the formulas themselves and to reflect changes in the underlying data. Recalculation can affect performance in the following ways:

- The values in a calculated column are computed and stored in the model. To update the values in the calculated column, you must process the model using one of three processing commands - Process Full, Process Data, or Process Recalc. The result of the formula must always be recalculated for the entire column, whenever you change the formula.
- The values calculated by measures are dynamically evaluated whenever a user adds the measure to a pivot table or open a report; as the user modifies the context, values returned by the measure change. The results of the measure always reflect the latest in the in-memory cache.

Processing and recalculation have no effect on row filter formulas unless the result of a recalculation returns a different value, thus making the row queryable or not queryable by role members.

Troubleshooting errors in formulas

If you get an error when defining a formula, the formula might contain either a *syntactic error*, *semantic error*, or *calculation error*.

Syntactic errors are the easiest to resolve. They typically involve a missing parenthesis or comma. For help with the syntax of individual functions, see [DAX Function Reference](#).

The other type of error occurs when the syntax is correct, but the value or the column referenced does not make sense in the context of the formula. Such semantic and calculation errors might be caused by any of the following problems:

- The formula refers to a non-existing column, table, or function.
- The formula appears to be correct, but when the data engine fetches the data it finds a type mismatch, and raises an error.
- The formula passes an incorrect number or type of parameters to a function.
- The formula refers to a different column that has an error, and therefore its values are invalid.
- The formula refers to a column that has not been processed, meaning it has metadata but no actual data to use for calculations.

In the first four cases, DAX flags the entire column that contains the invalid formula. In the last case, DAX grays out the column to indicate that the column is in an unprocessed state.

Measures in tabular models

10/25/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In tabular models, a measure is a calculation created using a DAX formula for use in a reporting client. Measures are evaluated based on fields, filters, and slicers users select in the reporting client application.

Benefits

Measures can be based on standard aggregation functions, such as AVERAGE, COUNT, or SUM, or you can define your own formula by using DAX. In addition to the formula, each measure has properties defined by the measure data type, such as Name, Table Detail, Format, and Decimal Places.

When measures have been defined in a model, users can then add them to a report or PivotTable. Depending on perspectives and roles, measures appear in the Field List with their associated table, and are available to all users of the model. Measures are usually created in Fact tables; however, measures can be independent of the table it is associated with.

It is important to understand the fundamental differences between a calculated column and a measure. In a calculated column, a formula evaluates to a value for each row in the column. For example, in a FactSales table, a calculated column named TotalProfit with the following formula calculates a value for total profit for each row (one row per sale) in the FactSales table:

```
=[SalesAmount] - [TotalCost] - [ReturnAmount]
```

The TotalProfit calculated column can then be used in a reporting client just as any other column.

A measure, on the other hand, evaluates to a value based on a user selection; a filter context set in a PivotTable or report. For example, a measure in the FactSales table is created with the following formula:

```
Sum of TotalProfit: =SUM([TotalProfit])
```

A sales analyst, using Excel, wants to know the total profit for a category of products. Each product category is comprised of multiple products. The sales analyst selects the ProductCategoryName column and adds it to the Row Labels filter window of a PivotTable; a row for each product category is then displayed in the PivotTable. The user then selects the Sum of TotalProfit measure. A measure will by default be added to the Values filter window. The measure calculates the sum of total profit and displays the results for each product category. The sales analyst can then further filter the sum of total profit for each product category by using a slicer, for example, adding CalendarYear as a slicer to view the sum of total profit for each product category by year.

| PRODUCTCATEGORYNAME | SUM OF TOTALPROFIT |
|------------------------|--------------------|
| Audio | \$2,731,061,308.69 |
| Cameras and Camcorders | \$620,623,675.75 |
| Computers | \$392,999,044.59 |

| PRODUCTCATEGORYNAME | SUM OF TOTALPROFIT |
|---------------------|---------------------------|
| Tv and Video | \$946,989,702.51 |
| Grand Total | \$4,691,673,731.53 |

Defining measures by using the measure grid

Measures are created at design time by using the measure grid in the model designer. Each table has a measure grid. By default, the measure grid is displayed below each table in the model designer. You can also choose not to view the measure grid for a particular table. To toggle the display of a table's measure grid, click the **Table** menu, and then click **Show Measure Grid**.

In the measure grid, you can create measures in the following ways:

- Click on an empty cell in the measure grid, and then type a DAX formula in the formula bar. When you click ENTER to complete the formula, the measure will then appear in the cell in the measure grid.
- Create a measure using a standard aggregation function by clicking on a column, then clicking on the AutoSum button (Σ) on the toolbar, and then clicking on a standard aggregation function. Standard aggregations are: Sum, Average, Count, DistinctCount, Max, Min. Measures created using the AutoSum button will always appear in the Measure grid directly beneath the column.

By default, when using AutoSum, the name of the measure is defined by the name of the associated column followed by a colon, followed by the formula. The name can be changed in the formula bar or in the **Measure Name** property setting in the Properties window. When creating a measure by using a custom formula, you can type a name in the formula bar, followed by a colon, then followed by the formula, or you can type a name in the **Measure Name** property setting in the Properties window.

It's important to name measures carefully. The measure name will appear with the associated table in the Field List of the reporting client. A KPI will also be named according to the base measure. A measure cannot have the same name as any column in any table in the model.

TIP

You can group measures from multiple tables into one table by creating an empty table, and then moving or create new measures into it. Keep in-mind, you may need to include table names in DAX formulas when referencing columns in other tables.

If perspectives have been defined for the model, measures are not automatically added to any of those perspectives. You must manually add measures to a perspective by using the Perspectives dialog box. To learn more, see [Perspectives](#).

Measure Properties

Each measure has properties that define it. Measure properties, along with the associated column properties can be edited in the Properties window. Measures have the following properties:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|--------------------|-----------------|---|
| Description | Blank | Description of the measure. The description will not appear with the measure in a reporting client. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------|--|--|
| Format | Automatically determined from the data type of the column referenced in the formula expression. | Format of the measure. For example, currency or percentage. |
| Formula | The formula entered in the formula bar when the measure was created. | The formula of the measure. |
| Measure Name | If AutoSum is used, the measure name will precede the column name followed by a colon. If a custom formula is entered, type a name followed by a colon, and then type the formula. | The name of the measure as it is displayed in a reporting client Field List. |

Using a Measure in a KPI

A KPI (Key Performance Indicator) is defined by a *Base* value, defined by a measure, against a *Target* value, also defined by a measure or by an absolute value. A KPI also includes *Status*, a calculation where the Base value evaluates against the Target value between thresholds, displayed in graphical format. KPIs are often used by business professionals to identify trends in critical business metrics.

Any measure can serve as the Base measure of a KPI. To create a KPI, in the measure grid, right-click a measure, and then click **Create KPI**. The Key Performance Indicator dialog box appears where you can then specify a target value (defined by a measure or an absolute value) and define status thresholds, and a graphic type. To learn more, see [KPIs](#).

Create and manage measures

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A measure is a formula that is created for use in a report or Excel PivotTable (or PivotChart). Measures can be based on standard aggregation functions, such as COUNT or SUM, or you can define your own formula by using DAX. The tasks in this topic describe how to create and manage measures by using a table's measure grid.

Tasks

To create and manage measures, you will use a table's measure grid. You can view the measure grid for a table in the model designer in Data View only. You cannot create measures or view the measure grid when in Diagram View; however, you can view existing measures in Diagram View. To show the measure grid for a table, click the **Table** menu, and then click **Show Measure Grid**.

To create a measure using a standard aggregation formula

- Click on the column for which you want to create the measure, then click the **Column** menu, then point to **AutoSum**, and then click an aggregation type.

The measure will be created automatically with a default name, followed by the formula in the first cell in the measure grid directly beneath the column.

To create a measure using a custom formula

- In the measure grid, beneath the column for which you want to create the measure, click a cell, then in the formula bar, type a name, followed by a colon (:), followed by an equals sign (=), followed by the formula. Press ENTER to accept the formula.

To edit measure properties

- In the measure grid, click a measure, and then In the **Properties** window, type or select a different property value.

To rename a measure

- In the measure grid, click on a measure, and then In the **Properties** window, in **Measure Name**, type a new name, and then click ENTER.

You can also rename a measure in the formula bar. The measure name precedes the formula, followed by a colon.

To delete a measure

- In the measure grid, right-click a measure, and then click **Delete**.

Calculation groups

10/22/2019 • 11 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server 2019 and later Analysis Services Azure Analysis Services Power BI Premium

Calculation groups can significantly reduce the number of redundant measures by grouping common measure expressions as *calculation items*. Calculation groups are supported in tabular models at the 1500 and higher compatibility level.

This article describes:

- Benefits
- How calculation groups work
- Dynamic format strings
- Precedence
- Sideways recursion
- Ordering
- How to create
- Limitations

Benefits

Calculation groups address an issue in complex models where there can be a proliferation of redundant measures using the same calculations - most common with time-intelligence calculations. For example, a sales analyst wants to view sales totals and orders by month-to-date (MTD), quarter-to-date (QTD), year-to-date (YTD), orders year-to-date for the previous year (PY), and so on. The data modeler has to create separate measures for each calculation, which can lead to dozens of measures. For the user, this can mean having to sort through just as many measures, and apply them individually to their report.

Let's first take a look at how calculation groups appear to users in a reporting tool like Power BI. We'll then take a look at what makes up a calculation group, and how they're created in a model.

Calculation groups are shown in reporting clients as a table with a single column. The column isn't like a typical column or dimension, instead it represents one or more reusable calculations, or *calculation items* that can be applied to any measure already added to the Values filter for a visualization.

In the following animation, a user is analyzing sales data for years 2012 and 2013. Before applying a calculation group, the common base measure **Sales** calculates a sum of total sales for each month. The user then wants to apply time-intelligence calculations to get sales totals for month to date, quarter to date, year to date, and so on. Without calculation groups, the user would have to select individual time-intelligence measures.

With a calculation group, in this example named **Time Intelligence**, when the user drags the **Time Calculation** item to the **Columns** filter area, each calculation item appears as a separate column. Values for each row are calculated from the base measure, **Sales**.

The screenshot shows a Power BI Desktop interface. On the left is a PivotTable visual with columns for 'CalendarYear' and 'Sales'. The data is grouped by year (2012, 2013) and month. The 'Sales' column shows values like \$495,364 for January 2012 and \$1,874,360 for December 2013. On the right is the 'Fields' pane, which lists several DAX measures and tables: Averages, Currency Conversion, DimCurrency, DimCustomer, DimDate, DimProduct, FactCurrencyRate, FactInternetSales, Time Intelligence, and Time Calculation. The 'Time Calculation' measure is currently selected.

Calculation groups work with **explicit** DAX measures. In this example, **Sales** is an explicit measure already created in the model. Calculation groups do not work with implicit DAX measures. For example, in Power BI implicit measures are created when a user drags columns onto visuals to view aggregated values, without creating an explicit measure. At this time, Power BI generates DAX for implicit measures written as inline DAX calculations - meaning implicit measures cannot work with calculation groups. A new model property visible in the Tabular Object Model (TOM) has been introduced, **DiscourageImplicitMeasures**. Currently, in order to create calculation groups this property must be set to **true**. When set to true, Power BI Desktop in Live Connect mode disables creation of implicit measures.

Calculation groups also support Multidimensional Data Expressions (MDX) queries. This means, Microsoft Excel users, which query tabular data models by using MDX, can take full advantage of calculation groups in worksheet PivotTables and charts.

How they work

Now that you've seen how calculation groups benefit users, let's take a look at how the Time Intelligence calculation group example shown is created.

Before we go into the details, let's introduce some new DAX functions specifically for calculation groups:

SELECTEDMEASURE - Used by expressions for calculation items to reference the measure that is currently in context. In this example, the Sales measure.

SELECTEDMEASURENAME - Used by expressions for calculation items to determine the measure that is in context by name.

ISSELECTEDMEASURE - Used by expressions for calculation items to determine the measure that is in context is specified in a list of measures.

SELECTEDMEASUREFORMATSTRING - Used by expressions for calculation items to retrieve the format string of the measure that is in context.

Time Intelligence example

Table name - **Time Intelligence**

Column name - **Time Calculation**

Precedence - **20**

Time Intelligence calculation items

Current

```
SELECTEDMEASURE()
```

MTD

```
CALCULATE(SELECTEDMEASURE(), DATESMTD(DimDate[Date]))
```

QTD

```
CALCULATE(SELECTEDMEASURE(), DATESQTD(DimDate[Date]))
```

YTD

```
CALCULATE(SELECTEDMEASURE(), DATESYTD(DimDate[Date]))
```

PY

```
CALCULATE(SELECTEDMEASURE(), SAMEPERIODLASTYEAR(DimDate[Date]))
```

PY MTD

```
CALCULATE(  
    SELECTEDMEASURE(),  
    SAMEPERIODLASTYEAR(DimDate[Date]),  
    'Time Intelligence'[Time Calculation] = "MTD"  
)
```

PY QTD

```
CALCULATE(  
    SELECTEDMEASURE(),  
    SAMEPERIODLASTYEAR(DimDate[Date]),  
    'Time Intelligence'[Time Calculation] = "QTD"  
)
```

PY YTD

```
CALCULATE(  
    SELECTEDMEASURE(),  
    SAMEPERIODLASTYEAR(DimDate[Date]),  
    'Time Intelligence'[Time Calculation] = "YTD"  
)
```

YOY

```
SELECTEDMEASURE() -  
CALCULATE(  
    SELECTEDMEASURE(),  
    'Time Intelligence'[Time Calculation] = "PY"  
)
```

YOY%

```
DIVIDE(
    CALCULATE(
        SELECTEDMEASURE(),
        'Time Intelligence'[Time Calculation]="YOY"
    ),
    CALCULATE(
        SELECTEDMEASURE(),
        'Time Intelligence'[Time Calculation]="PY"
    ),
)
```

To test this calculation group, execute a DAX query in SSMS or the open-source [DAX Studio](#). Note: YOY and YOY% are omitted from this query example.

Time Intelligence query

```
EVALUATE
CALCULATETABLE (
    SUMMARIZECOLUMNS (
        DimDate[CalendarYear],
        DimDate[EnglishMonthName],
        "Current", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "Current" ),
        "QTD", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "QTD" ),
        "YTD", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "YTD" ),
        "PY", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "PY" ),
        "PY QTD", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "PY QTD" ),
        "PY YTD", CALCULATE ( [Sales], 'Time Intelligence'[Time Calculation] = "PY YTD" )
    ),
    DimDate[CalendarYear] IN { 2012, 2013 }
)
```

Time Intelligence query return

The return table shows calculations for each calculation item applied. For example, see QTD for March 2012 is the sum of January, February and March 2012.

| CalendarYear | EnglishMonthName | Current | QTD | YTD | PY | PY QTD | PY YTD |
|--------------|------------------|--------------|--------------|---------------|------------|--------------|--------------|
| 2012 | January | \$ 495,364 | \$ 495,364 | \$ 495,364 | \$ 469,824 | \$ 469,824 | \$ 469,824 |
| 2012 | February | \$ 506,994 | \$ 1,002,358 | \$ 1,002,358 | \$ 466,335 | \$ 936,159 | \$ 936,159 |
| 2012 | March | \$ 373,483 | \$ 1,375,841 | \$ 1,375,841 | \$ 485,199 | \$ 1,421,357 | \$ 1,421,357 |
| 2012 | April | \$ 400,336 | \$ 400,336 | \$ 1,776,177 | \$ 502,074 | \$ 502,074 | \$ 1,923,431 |

Dynamic format strings

Dynamic format strings with calculation groups allow conditional application of format strings to measures without forcing them to return strings.

Tabular models support dynamic formatting of measures by using DAX's **FORMAT** function. However, the **FORMAT** function has the disadvantage of returning a string, forcing measures that would otherwise be numeric to also be returned as a string. This can have some limitations, such as not working with most Power BI visuals depending on numeric values, like charts.

Dynamic format strings for time-intelligence

If we look at the Time Intelligence example shown above, all the calculation items except **YOY%** should use the format of the current measure in context. For example, **YTD** calculated on the Sales base measure should be currency. If this were a calculation group for something like an Orders base measure, the format would be numeric. **YOY%**, however, should be a percentage regardless of the format of the base measure.

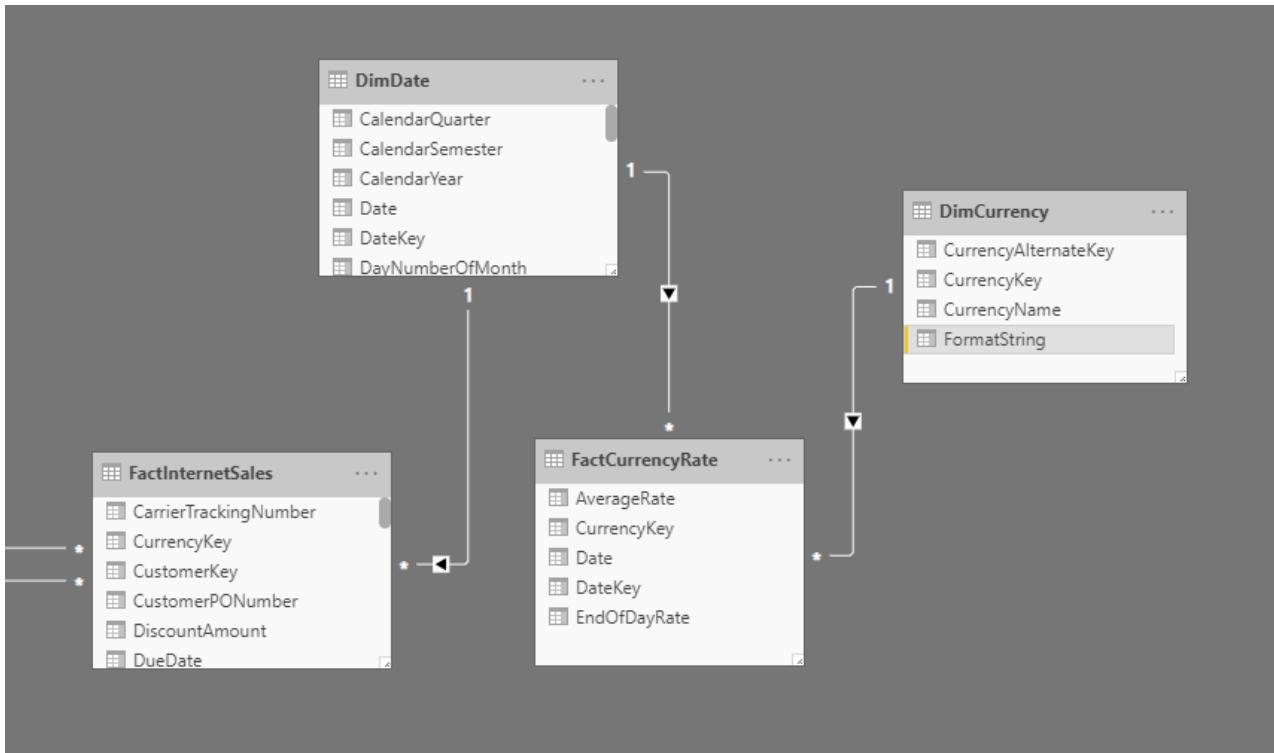

For **YOY%**, we can override the format string by setting the format string expression property to **0.00%:-0.00%;0.00%**. To learn more about format string expression properties, see [MDX Cell Properties - FORMAT STRING Contents](#).

In this matrix visual in Power BI, you see **Sales Current/YOY** and **Orders Current/YOY** retain their respective base measure format strings. **Sales YOY%** and **Orders YOY%**, however, overrides the format string to use *percentage* format.

| Time Calculation | Current | | YOY | | YOY% | | |
|------------------|--------------|-------|-------------|-------|---------|----------|--------|
| | CalendarYear | Sales | Orders | Sales | Orders | Sales | Orders |
| 2012 | | | | | | | |
| January | \$495,364 | 252 | \$25,540 | 108 | 5.44% | 75.00% | |

| December | \$1,874,360 | 6231 | \$1,249,858 | 5744 | 200.14% | 1179.47% | |

Dynamic format strings for currency conversion

Dynamic format strings provide easy currency conversion. Consider the following Adventure Works data model. It's modeled for *one-to-many* currency conversion as defined by [Conversion types](#).

A **FormatString** column is added to the **DimCurrency** table and populated with format strings for the respective currencies.

| | CurrencyKey | CurrencyAlternateKey | CurrencyName | FormatString |
|---|-------------|----------------------|----------------------|--|
| 1 | 16 | BRL | Brazilian Real | "R\$" #,0.00;"R\$" #,0.00;"R\$" #,0.00 |
| 2 | 36 | EUR | EURO | "€" #,0.00;"€" #,0.00;"€" #,0.00 |
| 3 | 98 | GBP | United Kingdom Pound | "£"#,0.00;"£"#,0.00;"£"#,0.00 |
| 4 | 102 | JPY | Yen | "¥"#,0.00;"¥"#,0.00;"¥"#,0.00 |
| 5 | 85 | SAR | Saudi Riyal | #,0.00 ".„„" 0.00#, ".„„" 0.00#, ".„„" |
| 6 | 100 | USD | US Dollar | \$#,0.00;(\$#,0.00);\$#,0.00 |

For this example, the following calculation group is then defined as:

Currency Conversion example

Table name - **Currency Conversion**

Column name - **Conversion Calculation**

Precedence - 5

Calculation items for Currency Conversion

No Conversion

```
SELECTEDMEASURE()
```

Converted Currency

```
IF(
    //Check one currency in context & not US Dollar, which is the pivot currency:
    SELECTEDVALUE( DimCurrency[CurrencyName], "US Dollar" ) = "US Dollar",
    SELECTEDMEASURE(),
    SUMX(
        VALUES(DimDate[Date]),
        CALCULATE( DIVIDE( SELECTEDMEASURE(), MAX(FactCurrencyRate[EndOfDayRate]) ) )
    )
)
```

Format string expression

```

SELECTEDVALUE(
    DimCurrency[FormatString],
    SELECTEDMEASUREFORMATSTRING()
)

```

The format string expression must return a scalar string. It uses the new **SELECTEDMEASUREFORMATSTRING** function to revert to the base measure format string if there are multiple currencies in filter context.

The following animation shows the dynamic format currency conversion of the **Sales** measure in a report.

The screenshot shows the Power BI Desktop interface. On the left, a table visualization displays monthly sales data for the year 2013. The columns are 'CalendarYear' and 'Sales'. The data looks like this:

| CalendarYear | Sales |
|--------------|-------------|
| January | \$857,690 |
| February | \$771,349 |
| March | \$1,049,907 |
| April | \$1,046,023 |
| May | \$1,284,593 |
| June | \$1,643,178 |
| July | \$1,371,676 |
| August | \$1,551,066 |
| September | \$1,447,496 |
| October | \$1,673,293 |
| November | \$1,780,920 |
| December | \$1,874,360 |

On the right, the 'Fields' pane is open, showing the structure of the data model. A tooltip highlights the 'DimCurrency' table, specifically the 'CurrencyName' column. The Fields pane lists various dimensions and fact tables, including 'Averages', 'Currency Conversion', 'DimCurrency' (with columns: CurrencyAlternateKey, CurrencyKey, CurrencyName, FormatString), 'DimCustomer', 'DimDate', 'DimProduct', 'FactCurrencyRate', 'FactInternetSales', and 'Time Intelligence'.

Precedence

Precedence is a property defined for a calculation group. It specifies the order of evaluation when there is more than one calculation group. A higher number indicates greater precedence, meaning it will be evaluated before calculation groups with lower precedence.

For this example, we'll use same model as the time-intelligence example above, but also add an **Averages** calculation group. The Averages calculation group contains average calculations that are independent of traditional time intelligence in that they don't change the date filter context - they just apply average calculations within it.

In this example, a daily average calculation is defined. Calculations such as average barrels of oil per day are common in oil-and-gas applications. Other common business examples include store sales average in retail.

While such calculations are calculated independently of time-intelligence calculations, there may well be a requirement to combine them. For example, a user might want to see barrels of oil per day YTD to view the daily oil rate from the beginning of the year to the current date. In this scenario, precedence should be set for calculation items.

Averages example

Table name is **Averages**.

Column name is **Average Calculation**.

Precedence is **10**.

Calculation items for Averages

No Average

```
SELECTEDMEASURE()
```

Daily Average

```
DIVIDE(SELECTEDMEASURE(), COUNTROWS(DimDate))
```

Here's an example of a DAX query and return table:

Averages query

```
EVALUATE
CALCULATETABLE (
    SUMMARIZECOLUMNS (
        DimDate[CalendarYear],
        DimDate[EnglishMonthName],
        "Sales", CALCULATE (
            [Sales],
            'Time Intelligence'[Time Calculation] = "Current",
            'Averages'[Average Calculation] = "No Average"
        ),
        "YTD", CALCULATE (
            [Sales],
            'Time Intelligence'[Time Calculation] = "YTD",
            'Averages'[Average Calculation] = "No Average"
        ),
        "Daily Average", CALCULATE (
            [Sales],
            'Time Intelligence'[Time Calculation] = "Current",
            'Averages'[Average Calculation] = "Daily Average"
        ),
        "YTD Daily Average", CALCULATE (
            [Sales],
            'Time Intelligence'[Time Calculation] = "YTD",
            'Averages'[Average Calculation] = "Daily Average"
        )
),
DimDate[CalendarYear] = 2012
)
```

Averages query return

| CalendarYear | EnglishMonthName | InternetTotalSales | YTD | Daily Average | YTD Daily Average |
|----------------|------------------|--------------------|-----------|---------------|-------------------|
| 2012 January | \$ 495,364 | \$ 495,364 | \$ 15,979 | \$ 15,979 | |
| 2012 February | \$ 506,994 | \$1,002,358 | \$ 17,483 | \$ 16,706 | |
| 2012 March | \$ 373,483 | \$1,375,841 | \$ 12,048 | \$ 15,119 | |
| 2012 April | \$ 400,336 | \$1,776,177 | \$ 13,345 | \$ 14,679 | |
| 2012 May | \$ 358,878 | \$2,135,055 | \$ 11,577 | \$ 14,046 | |
| 2012 June | \$ 555,160 | \$2,690,215 | \$ 18,505 | \$ 14,781 | |
| 2012 July | \$ 444,558 | \$3,134,773 | \$ 14,341 | \$ 14,717 | |
| 2012 August | \$ 523,917 | \$3,658,691 | \$ 16,901 | \$ 14,995 | |
| 2012 September | \$ 486,177 | \$4,144,868 | \$ 16,206 | \$ 15,127 | |
| 2012 October | \$ 535,159 | \$4,680,028 | \$ 17,263 | \$ 15,344 | |
| 2012 November | \$ 537,956 | \$5,217,983 | \$ 17,932 | \$ 15,576 | |
| 2012 December | \$ 624,502 | \$5,842,485 | \$ 20,145 | \$ 15,963 | |

The following table shows how the March 2012 values are calculated.

| COLUMN NAME | CALCULATION |
|---------------|--|
| YTD | Sum of Sales for Jan, Feb, Mar 2012
= 495,364 + 506,994 + 373,483 |
| Daily Average | Sales for Mar 2012 divided by # of days in March
= 373,483 / 31 |

| COLUMN NAME | CALCULATION |
|-------------------|--|
| YTD Daily Average | YTD for Mar 2012 divided by # of days in Jan, Feb, and Mar
= $1,375,841 / (31 + 29 + 31)$ |

Here's the definition of the YTD calculation item, applied with precedence of **20**.

```
CALCULATE(SELECTEDMEASURE(), DATESYTD(DimDate[Date]))
```

Here's Daily Average, applied with a precedence of **10**.

```
DIVIDE(SELECTEDMEASURE(), COUNTROWS(DimDate))
```

Since the precedence of the Time Intelligence calculation group is higher than that of the Averages calculation group, it's applied as broadly as possible. The YTD Daily Average calculation applies YTD to both the numerator and the denominator (count of days) of the daily average calculation.

This is equivalent to the following expression:

```
CALCULATE(DIVIDE(SELECTEDMEASURE(), COUNTROWS(DimDate)), DATESYTD(DimDate[Date]))
```

Not this expression:

```
DIVIDE(CALCULATE(SELECTEDMEASURE(), DATESYTD(DimDate[Date])), COUNTROWS(DimDate))
```

Sideways recursion

In the Time Intelligence example above, some of the calculation items refer to others in the same calculation group. This is called *sideways recursion*. For example, **YOY%** references both **YOY** and **PY**.

```
DIVIDE(
    CALCULATE(
        SELECTEDMEASURE(),
        'Time Intelligence'[Time Calculation]="YOY"
    ),
    CALCULATE(
        SELECTEDMEASURE(),
        'Time Intelligence'[Time Calculation]="PY"
    )
)
```

In this case, both expressions are evaluated separately because they are using different calculate statements. Other types of recursion are not supported.

Single calculation item in filter context

In our Time Intelligence example, the **PY YTD** calculation item has a single calculate expression:

```

CALCULATE(
    SELECTEDMEASURE(),
    SAMEPERIODLASTYEAR(DimDate[Date]),
    'Time Intelligence'[Time Calculation] = "YTD"
)

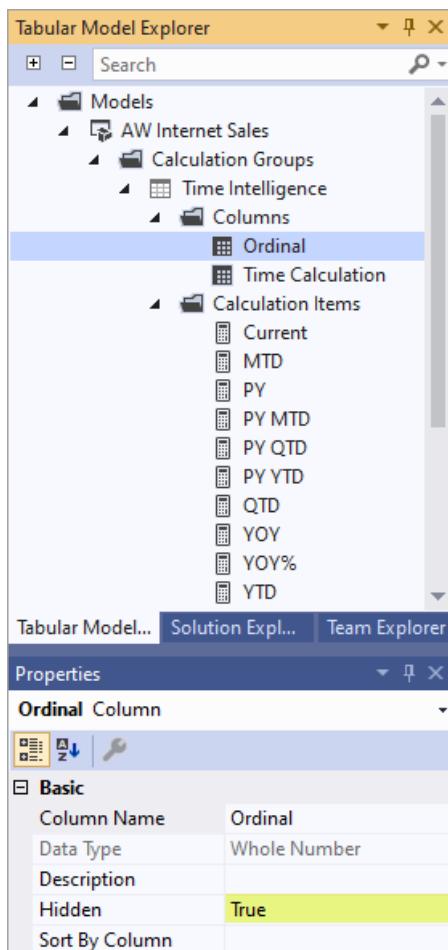

```

The YTD argument to the CALCULATE() function overrides the filter context to reuse the logic already defined in the YTD calculation item. It's not possible to apply both PY and YTD in a single evaluation. Calculation groups are *only applied* if a single calculation item from the calculation group is in filter context.

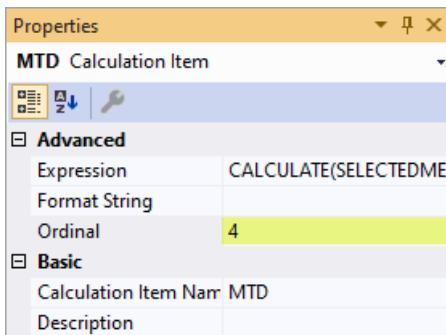

Ordering

By default, when a column from a calculation group is placed in a report, calculation items are ordered alphabetically by name in the report. The order in which calculation items appear in a report can be changed by specifying the **Ordinal** property. Specifying calculation item order with the **Ordinal** property does not change [precedence](#), the order in which calculation items are evaluated. It also does not change the order in which calculation items appear in Tabular Model Explorer.

To specify the ordinal property for calculation items, you must add a second column to the calculation group. Unlike the default column where Data Type is Text, a second column used for ordering calculation items has a Whole Number data type. The only purpose for this column is to specify the numeric order in which calculation items in the calculation group appear. Because this column provides no value in a report, it's best to set the **Hidden** property to True.

After a second column is added to the calculation group, you can specify the **Ordinal** property value for calculation items you want to order.

To learn more, see [To order calculation items](#).

Create a calculation group

Calculation groups are supported in Visual Studio with Analysis Services Projects VSIX update 2.9.2 and later. Calculation groups can also be created by using Tabular Model Scripting Language (TMSL) or the open source [Tabular Editor](#).

To create a calculation group by using Visual Studio

1. In Tabular Model Explorer, right-click **Calculation Groups**, and then click **New Calculation Group**. By default, a new calculation group will have a single column and a single calculation item.
2. Use **Properties** to change the name and enter a description for the calculation group, column, and default calculation item.
3. To enter a DAX formula expression for the default calculation item, right-click and then click **Edit Formula** to open DAX Editor. Enter a valid expression.
4. To add additional calculation items, right-click **Calculation Items**, and then click **New Calculation Item**.

To order calculation items

1. In Tabular Model Explorer, right-click a calculation group, and then click **Add column**.
2. Name the column **Ordinal** (or something similar), enter a description, and then set the **Hidden** property to **True**.
3. For each calculation item you want to order, set the **Ordinal** property to a positive number. Each number is sequential, for example, a calculation item with an **Ordinal** property of 1 will appear first, a property of 2 will appear second, and so on. Calculation items with the default -1 are not included in the ordering, but will appear before ordered items in a report.

Limitations

[Object level security](#) (OLS) defined on calculation group tables is not supported. However, OLS can be defined on other tables in the same model. If a calculation item refers to an OLS secured object, a generic error is returned.

[Row level security](#) (RLS) is not supported. Define RLS on tables in the same model, but not on calculation groups themselves (directly or indirectly).

[Detail Rows Expressions](#) are not supported with calculation groups.

KPIs

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A *KPI* (Key Performance Indicator), in a tabular model, is used to gauge performance of a value, defined by a *Base* measure, against a *Target* value, also defined by a measure or by an absolute value. This article provides tabular model authors a basic understanding of KPIs in a tabular model.

Benefits

In business terminology, a Key Performance Indicator (KPI) is a quantifiable measurement for gauging business objectives. A KPI is frequently evaluated over time. For example, the sales department of an organization may use a KPI to measure monthly gross profit against projected gross profit. The accounting department may measure monthly expenditures against revenue to evaluate costs, and a human resources department may measure quarterly employee turnover. Each is an example of a KPI. Business professionals frequently consume KPIs that are grouped together in a business scorecard to obtain a quick and accurate historical summary of business success or to identify trends.

A KPI in a tabular model includes:

Base Value

A Base value is defined by a measure that resolves to a value. This value, for example, can be an aggregate of actual Sales or a calculated measure such as Profit for a given period.

Target value

A Target value is defined by a measure that resolves to a value, or by an absolute value. For example, a target value could be the amount by which the business managers of an organization want to increase sales or profit.

Status thresholds

A Status threshold is defined by the range between a low and high threshold or by a fixed value. The Status threshold displays with a graphic to help users easily determine the status of the Base value compared to the Target value.

Example

The sales manager at Adventure Works wants to create a PivotTable that she can use to quickly display whether or not sales employees are meeting their sales quota for a given period (year). For each sales employee, she wants the PivotTable to display the actual sales amount in dollars, the sales quota amount in dollars, and a simple graphic display showing the status of whether or not each sales employee is below, at, or above their sales quota. She wants to be able to slice the data by year.

To do this, the sales manager enlists the help of her organization's BI solution developer to add a Sales KPI to the AdventureWorks Tabular Model. The sales manager will then use Excel to connect to the Adventure Works Tabular Model as a data source and create a PivotTable with the fields (measures and KPI) and slicers to analyze whether or not the sales force is meeting their quotas.

In the model, a measure on the SalesAmount column in the FactResellerSales table, which gives the actual sales amount in dollars for each sales employee is created. This measure will define the Base value of the KPI.

The Sales measure is created with the following formula:

```
Sales:=Sum(FactResellerSales[SalesAmount])
```

The SalesAmountQuota column in the FactSalesQuota table has a sales amount quota defined for each employee. The values in this column will serve as the Target measure (value) in the KPI.

The SalesAmountQuota measure is created with the following formula:

```
Target_SalesAmountQuota:=Sum(FactSalesQuota[SalesAmountQuota])
```

NOTE

There is a relationship between the EmployeeKey column in the FactSalesQuota table and the EmployeeKey in the DimEmployees table. This relationship is necessary so that each sales employee in the DimEmployee table is represented in the FactSalesQuota table.

Now that measures have been created to serve as the Base value and Target value of the KPI, the Sales measure is extended to a new Sales KPI. In the Sales KPI, the Target SalesAmountQuota measure is defined as the Target value. The Status threshold is defined as a range by percentage, the target of which is 100% meaning actual sales defined by the Sales measure met the quota amount defined in the Target SalesAmounQuota measure. Low and High percentages are defined on the status bar, and a graphic type is selected.

The sales manager can now create a PivotTable adding the KPI's Base value, Target value, and Status to the Values field. The Employees column is added to the RowLabel field, and the CalendarYear column is added as a Slicer.

The sales manager can now slice by year the actual sales amount, sales quota amount, and status for each sales employee. She can analyze sales trends over years to determine whether or not she needs to adjust the sales quota for a sales employee.

Create and edit KPIs

To create KPIs, in the model designer, you will use the Key Performance Indicator dialog box. Since KPIs must be associated with a measure, you create a KPI by extending a measure that evaluates to a Base value, and then either creating a measure that evaluates to a Target value or by entering an absolute value. After the Base measure (value) and Target value is defined, you can then define the status threshold parameters between the Base and Target values. The status is displayed in a graphical format using selectable icons, bars, graphs, or colors. The Base and Target values, as well as the Status can then be added to a report or PivotTable as values that can be sliced against other data fields.

To view the Key Performance Indicator dialog box, in the measure grid for a table, right click a measure that will serve as the Base value, and then click **Create KPI**. After a measure has been extended to a KPI as a Base value, an icon will appear alongside the measure name in the measure grid identifying the measure as associated with a KPI.

Create and manage KPIs

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This article describes how to create, edit, or delete a KPI (Key Performance Indicator) in a tabular model. To create a KPI, you select a measure that evaluates to the KPI's Base value. You then use the Key Performance Indicator dialog box to select a second measure or an absolute value that evaluates to a target value. You can then define status thresholds that measure the performance between the Base and Target measures.

Tasks

IMPORTANT

Before creating a KPI, you must first create a Base measure that evaluates to a value. You then extend the Base measure to a KPI. How to create measures are described in another topic, [Create and Manage Measures](#). A KPI also requires a target value. This value can be from another pre-defined measure or an absolute value. Once you have extended a Base measure to a KPI, you can then select the target value and define status thresholds in the Key Performance Indicator dialog box.

To create a KPI

1. In the measure grid, right-click the measure that will serve as the Base measure (value), and then click **Create KPI**.
2. In the **Key Performance Indicator** dialog box, in **Define target value**, select from one of the following:
 - Select **Measure**, and then select a target measure from the listbox.
 - Select **Absolute value**, and then type a numerical value.
3. In **Define status thresholds**, click and slide the low and high threshold values.
4. In **Select icon style**, click an image type.
5. Click on **Descriptions**, and then type descriptions for KPI, Value, Status, and Target.

TIP

You can use the Analyze in Excel feature to test your KPI. For more information, see [Analyze in Excel](#).

To edit a KPI

- In the measure grid, right-click the measure that serves as the Base measure (value) of the KPI, and then click **Edit KPI Settings**.

To delete a KPI and the base measure

- In the measure grid, right-click the measure that serves as the Base measure (value) of the KPI, and then click **Delete**.

To delete a KPI, but keep the base measure

- In the measure grid, right-click the measure that serves as the Base measure (value) of the KPI, and then click **Delete KPI**.

ALT shortcuts

Hierarchies in tabular models

10/25/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Hierarchies, in tabular models, are metadata that define relationships between two or more columns in a table. Hierarchies can appear separate from other columns in a reporting client field list, making them easier for client users to navigate and include in a report.

Benefits

Tables can include dozens or even hundreds of columns with unusual column names in no apparent order. This can lead to an unordered appearance in reporting client field lists, making it difficult for users to find and include data in a report. Hierarchies can provide a simple, intuitive view of an otherwise complex data structure.

For example, in a Date table, you can create a Calendar hierarchy. Calendar Year is used as the top-most parent level, with Month, Week, and Day included as child levels (Calendar Year->Month->Week->Day). This hierarchy shows a logical relationship from Calendar Year to Day. A client user can then select Calendar Year from a Field List to include all levels in a PivotTable, or expand the hierarchy, and select only particular levels to be included in the PivotTable.

Because each level in a hierarchy is a representation of a column in a table, the level can be renamed. While not exclusive to hierarchies (any column can be renamed in a tabular model), renaming hierarchy levels can make it easier for users to find and include levels in a report. Renaming a level does not rename the column it references; it simply makes the level more identifiable. In our Calendar Year hierarchy example, in the Date table in Data View, the columns: CalendarYear, CalendarMonth, CalendarWeek, and CalendarDay were renamed to Calendar Year, Month, Week, and Day to make them more easily identifiable. Renaming levels has the additional benefit of providing consistency in reports, since users will less likely need to change column names to make them more readable in PivotTables, charts, etc.

Hierarchies can be included in perspectives. Perspectives define viewable subsets of a model that provide focused, business-specific, or application-specific viewpoints of the model. A perspective, for example, could provide users a viewable list (hierarchy) of only those data items necessary for their specific reporting requirements. For more information, see [Perspectives](#).

Hierarchies are not meant to be used as a security mechanism, but as a tool for providing a better user experience. All security for a particular hierarchy is inherited from the underlying model. Hierarchies cannot provide access to model objects to which a user does not already have access. Security for the model database must be resolved before access to objects in the model can be provided through a hierarchy. Security roles can be used to secure model metadata and data. For more information, see [Roles](#).

Defining hierarchies

You create and manage hierarchies by using the model designer in Diagram View. Creating and managing hierarchies is not supported in the model designer in Data View. To view the model designer in Diagram View, click the **Model** menu, then point to **Model View**, and then click **Diagram View**.

To create a hierarchy, right-click a column you want to specify as the parent level, and then click **Create Hierarchy**. You can multi-select any number of columns (within a single table) to include, or you can later add columns as child levels by clicking and dragging columns to the parent level. When multiple columns are selected, columns are automatically placed in an order based on cardinality. You can change the order by clicking and

dragging a column (level) to a different order or by using Up and Down navigation controls on the context menu. When adding a column as a child level, you can use auto-detect by dragging and dropping the column onto the parent level.

A column can appear in more than one hierarchy. Hierarchies cannot include non-column objects such as measures or KPIs. A hierarchy can be based on columns from within a single table only. If you multi-select a measure along with one or more columns, or if you select columns from multiple tables, the **Create Hierarchy** command is disabled in the context menu. To add a column from a different table, use the RELATED DAX function to add a calculated column that references the column from the related table. The function uses the following syntax: `=RELATED(Table Name[Column Name])`. For more information, see [RELATED Function](#).

By default, new hierarchies are named hierarchy1, hierarchy 2, etc. You should change hierarchy names to reflect the nature of the parent-child relationship, making them more identifiable to users.

After you have created hierarchies, you can test their efficacy by using the Analyze in Excel feature. For more information, see [Analyze in Excel](#).

[Roles](#)

Create and manage hierarchies

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Hierarchies can be created and managed in the model designer, in Diagram View. To view the model designer in Diagram View, in Visual Studio with Analysis Services projects, click the **Model** menu, then point to **Model View**, and then click **Diagram View**.

This article includes the following tasks:

- [Create a Hierarchy](#)
- [Edit a Hierarchy](#)
- [Delete a Hierarchy](#)

Create a hierarchy

You can create a hierarchy by using the columns and table context menu. When you create a hierarchy, a new parent level displays with selected columns as child levels.

To create a hierarchy from the context menu

1. In the model designer (Diagram View), in a table window, right-click on a column, and then click **Create Hierarchy**.

To select multiple columns, click each column, then right-click to open the context menu, and then click **Create Hierarchy**.

A parent hierarchy level is created at the bottom of the table window and the selected columns are copied under the hierarchy as child levels.

2. Type a name for the hierarchy.

You can drag additional columns into your hierarchy's parent level, which copies the columns. Drop the child level to place it where you want it to appear in the hierarchy.

NOTE

The Create Hierarchy command is disabled in the context menu if you multi-select a measure along with one or more columns or you select columns from multiple tables.

Edit a hierarchy

You can rename a hierarchy, rename a child level, change the order of the child levels, add additional columns as child levels, remove a child level from a hierarchy, show the source name of a child level (the column name), and hide a child level if it has the same name as the hierarchy parent level.

To change the name of a hierarchy or child level

1. Right-click the hierarchy parent level or a child level, and click **Rename**.
2. Type a new name or edit the existing name.

To change the order of a child level in a hierarchy

- Click and drag a child level into a new position in the hierarchy.
- Or, right-click a child level of the hierarchy, and then click Move Up to move the level up in the list, or click Move Down to move the level down in the list.
- Or, click a child level to select it, and then press Alt + Up Arrow to move the level up, or press Alt+Down Arrow to move the level down in the list.

To add another child level to a hierarchy

- Click and drag a column onto the parent level or into a specific location of the hierarchy. The column is copied as a child level of the hierarchy.
- Or, right-click a column, point to **Add to Hierarchy**, and then click the hierarchy.

NOTE

You can add a hidden column (a column that is hidden from reports) as a child level to the hierarchy. The child level is not hidden.

To remove a child level from a hierarchy

- Right-click a child level, and then click **Remove from Hierarchy**.
- Or, click a child level, and then press **Delete**.

NOTE

If you rename a hierarchy child level, it no longer shares the same name as the column that it is copied from. Use the **Show Source Name** command to see which column it was copied from.

To show a source name

- Right-click a hierarchy child level, and then click **Show Source Name**. The name of the column that it was copied from appears.

Delete a Hierarchy

To delete a hierarchy and remove its child levels

- Right-click the parent hierarchy level, and then click Delete Hierarchy.
- Or, click the parent hierarchy level, and then press Delete. This also removes all the child levels.

Partitions in tabular models

10/25/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Partitions divide a table into logical parts. Each partition can then be processed (Refreshed) independent of other partitions. Partitions created by using the Partitions dialog box in Visual Studio during model authoring apply to the model workspace database. When the model is deployed, the partitions defined for the model workspace database are duplicated in the deployed model database. You can further create and manage partitions for a deployed model database by using the Partitions dialog box in SSMS. Information provided in this topic describes partitions created during model authoring by using the Partition Manager dialog box in Visual Studio. For information about creating and managing partitions for a deployed model, see [Create and Manage Tabular Model Partitions](#).

Benefits

Partitions, in tabular models, divide a table into logical partition objects. Each partition can then be processed independent of other partitions. For example, a table may include certain row sets that contain data that rarely changes, but other row sets have data that changes often. In these cases, there is no need to process all of the data when you really just want to process a portion of the data. Partitions enable you to divide portions of data you need to process frequently from the data that can be processed less frequently.

Effective model design utilizes partitions to eliminate unnecessary processing and subsequent processor load on Analysis Services servers, while at the same time, making certain that data is processed and refreshed often enough to reflect the most recent data from data sources. How you implement and utilize partitions during model authoring can be very different from how partitions are implemented and utilized for deployed models. Keep in-mind that during the model authoring phase, you may be working with only a subset of the data that will ultimately be in your deployed model.

Processing partitions

For deployed models, processing occurs by using SSMS, or by running a script which includes the process command and specifies processing options and settings. When authoring models by using Visual Studio, you can run process operations on the workspace database by using a Process command from the Model menu or toolbar. A Process operation can be specified for a partition, a table, or all.

When a process operation is run, a connection to the data source is made using the data connection. New data is imported into the model tables, relationships and hierarchies are rebuilt for each table, and calculations in calculated columns and measures are re-calculated.

By further dividing a table into logical partitions, you can selectively determine what, when, and how the data in each partition is processed. When you deploy a model, processing of partitions can be completed manually using the Partitions dialog box in SSMS, or by using a script that executes a process command.

Partitions in the model workspace database

You can create new partitions, edit, merge, or delete partitions using the Partition Manager in Visual Studio. Depending on the compatibility level of the model you are authoring, Partition Manager provides two modes for selecting tables, rows, and columns for a partition: For tabular 1400 models, partitions are defined by using an M query, or you can use Design mode to open Query Editor. For tabular 1100, 1103, 1200 models, use Table Preview mode and SQL query mode.

Partitions in a deployed model database

When you deploy a model, the partitions for the deployed model database will appear as database objects in SSMS. You can create, edit, merge, and delete partitions for a deployed model by using the Partitions dialog box in SSMS. Managing partitions for a deployed model in SSMS is outside the scope of this topic. To learn about managing partitions in SSMS, see [Create and Manage Tabular Model Partitions](#).

Create and manage partitions in the workspace database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Partitions divide a table into logical parts. Each partition can then be processed (Refreshed) independently or in parallel with other partitions. Partitions can improve scalability and manageability of large databases. By default, each table has one partition that includes all columns. Tasks in this topic describe how to create and manage partitions in the model workspace database by using the **Partition Manager** dialog box in Visual Studio with Analysis Services projects.

After a model has been deployed to another Analysis Services instance, database administrators can create and manage partitions in the (deployed) model by using SQL Server Management Studio. For more information, see [Create and Manage Tabular Model Partitions](#).

NOTE

You cannot merge partitions in the model workspace database by using the Partition Manager dialog box. Partitions can be merged in a deployed model only by using SQL Server Management Studio.

Tasks

To create and manage partitions, you will use the **Partitions Manager** dialog box. To view the **Partitions Manager** dialog box, in Visual Studio with Analysis Services projects, click the **Table** menu, and then click **Partitions**.

To create a new partition

1. In the model designer, select the table for which you want to define a partition.
2. Click on the **Table** menu, and then click **Partitions**.
3. In **Partition Manager**, in the **Table** listbox, verify or select the table you want to partition, and then click **New**.
4. In **Partition Name**, type a name for the partition. By default, the name of the default partition will be incrementally numbered for each new partition.
5. You can select the rows and columns to be included in the partition by using Table Preview mode or by using a SQL query created using Query Editor mode.

To use Table Preview mode (default), click the **Table Preview** button near the upper-right corner of the preview window. Select the columns you want to include in the partition by selecting the checkbox next to the column name. To filter rows, right click a cell value, and click **Filter by Selected Cell Value**.

To use a SQL statement, click the **Query Editor** button near the upper-right corner of the preview window, then type or paste a SQL query statement into the query window. To validate your statement, click **Validate**. To use the Query Designer, click **Design**.

To copy a partition

1. In **Partition Manager**, in the **Table** listbox, verify or select the table that contains the partition you want to

copy.

2. In the **Partitions** list, select the partition you want to copy and then click **Copy**.

3. In **Partition Name**, type a new name for the partition.

To delete a partition

1. In **Partition Manager**, in the **Table** listbox, verify or select the table that contains the partition you want to delete.

2. In the **Partitions** list, select the partition you want to delete and then click **Delete**.

[Process partitions in the workspace database](#)

Process Partitions in the Workspace Database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Partitions divide a table into logical parts. Each partition can then be processed (Refreshed) independent of other partitions. The tasks in this topic describe how to process partitions in the model workspace database by using the **Process Partitions** dialog box in Visual Studio with Analysis Services projects.

After a model has been deployed to another Analysis Services instance, database administrators can create and manage partitions in the (deployed) model by using SQL Server Management Studio, by script, or by using an IS package. For more information, see [Create and Manage Tabular Model Partitions](#).

To process a partition

1. In Visual Studio with Analysis Services projects, click the **Model** menu, and then click **Process** (Refresh), and then click **Process Partitions**.
2. In the **Mode** listbox, select one of the following process modes:

| MODE | DESCRIPTION |
|------------------------|--|
| Process Default | Detects the process state of a partition object, and performs processing necessary to deliver unprocessed or partially processed partition objects to a fully processed state. Data for empty tables and partitions is loaded; hierarchies, calculated columns, and relationships are built or rebuilt. |
| Process Full | Processes a partition object and all the objects that it contains. When Process Full is run for an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object. |
| Process Data | Load data into a partition or a table without rebuilding hierarchies or relationships or recalculating calculated columns and measures. |
| Process Clear | Removes all data from a partition. |
| Process Add | Incrementally update partition with new data. |

3. In the **Process** checkbox column, select the partitions you want to process with the selected mode, and then click **Ok**.

[Create and Manage Partitions in the Workspace Database](#)

Perspectives in tabular models

10/25/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Perspectives, in tabular models, define viewable subsets of a model that provide focused, business-specific, or application-specific viewpoints of the model.

Benefits

Tabular models can be very complex for users to explore. A single model can represent the contents of a complete data warehouse with many tables, measures, and dimensions. Such complexity can be daunting to users who may only need to interact with a small part of the model in order to satisfy their business intelligence and reporting requirements.

In a perspective, tables, columns, and measures (including KPIs) are defined as field objects. You can select the viewable fields for each perspective. For example, a single model may contain product, sales, financial, employee, and geographic data. While a sales department requires product, sales, promotions, and geography data, they likely do not require employee and financial data. Similarly, a human resources department does not require data about sales promotions and geography.

When a user connects to a model (as a data source) with defined perspectives, the user can select the perspective they want to use. For example, when connecting to a model data source in Excel, users in Human Resources can select the Human Resources perspective on the Select Tables and Views page of the Data Connection Wizard. Only fields (tables, columns, and measures) defined for the Human Resources perspective will be visible in the PivotTable Field List.

Perspectives are not meant to be used as a security mechanism, but as a tool for providing a better user experience. All security for a particular perspective is inherited from the underlying model. Perspectives cannot provide access to model objects to which a user does not already have access. Security for the model database must be resolved before access to objects in the model can be provided through a perspective. Security roles can be used to secure model metadata and data. For more information, see [Roles](#).

Testing perspectives

When authoring a model, you can use the Analyze in Excel feature in the model designer to test the efficacy of the perspectives you have defined. From the **Model** menu in the model designer, when you click **Analyze in Excel**, before Excel opens, the **Choose Credentials and Perspective** dialog box appears. In this dialog, you can specify the current username, a different user, a role, and a perspective with which you will use to connect to the model workspace database as a data source and view data.

Related tasks

| TOPIC | DESCRIPTION |

| Create and Manage Perspectives | Describes how to create and manage perspectives using the Perspectives dialog box in the model designer. |

See also

[Roles](#)

[Hierarchies](#)

Create and manage perspectives

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Perspectives define viewable subsets of a model that provide focused, business-specific, or application-specific viewpoints of the model. The tasks in this topic describe how to create and manage perspectives by using the **Perspectives** dialog box in the model designer.

Tasks

To create perspectives, you will use the **Perspectives** dialog box, where you can add, edit, delete, copy, and view perspectives. To view the **Perspectives** dialog box, in Visual Studio with Analysis Services projects, click on the **Model** menu, and then click **Perspectives**.

To add a perspective

- To add a new perspective, click **New Perspective**. You can then check and uncheck field objects to be included and provide a name for the new perspective.

If you create an empty perspective with all of the field object fields, then a user using this perspective will see an empty Field List. Perspectives should contain at least one table and column.

To edit a perspective

- To modify a perspective, check and uncheck fields in the perspective's column, which adds and removes field objects from the perspective.

To rename a perspective

- When you hover over a perspective's column header (the name of the perspective), the **Rename** button appears. To rename the perspective, click **Rename**, and then enter a new name or edit the existing name.

To delete a perspective

- When you hover over a perspective's column header (the name of the perspective), the **Delete** button appears. To delete the perspective, click the **Delete** button, and then click **Yes** in the confirmation window.

To copy a perspective

- When you hover over a perspective's column header, the **Copy** button appears. To create a copy of that perspective, click the **Copy** button. A copy of the selected perspective is added as a new perspective to the right of existing perspectives. The new perspective inherits the name of the copied perspective and a *- Copy* annotation is appended to the end of the name. For example, if a copy of the *Sales* perspective is created, the new perspective is called *Sales - Copy*.

[Perspectives](#)

[Hierarchies](#)

Translations in tabular models

10/25/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

SQL Server 2017 adds translation string support for Tabular models. A single object in the model can have multiple translations of a name or description, making it possible to support multi-language versions within the model definition.

Translated strings are for object metadata only (names and descriptions of tables and columns) that appear in a client tool like an Excel PivotTable list. To use translated strings, the client connection specifies the culture. In the **Analysis in Excel** feature, you can choose the language from a drop-down list. For other tools, you might need to specify the culture in the connection string.

This feature is not intended loading translated data into a model. If you want to load translated data values, you should develop a processing strategy that includes extracting translated strings from a data source that provides them.

A typical workflow for adding translated metadata looks like this:

- Generate an empty translation JSON file that contains placeholders for each string translation
- Add string translations to the JSON file
- Import the translations back into the model
- Build, process or deploy the model
- Connect to the model using a client application that allows an LCID on the connection string

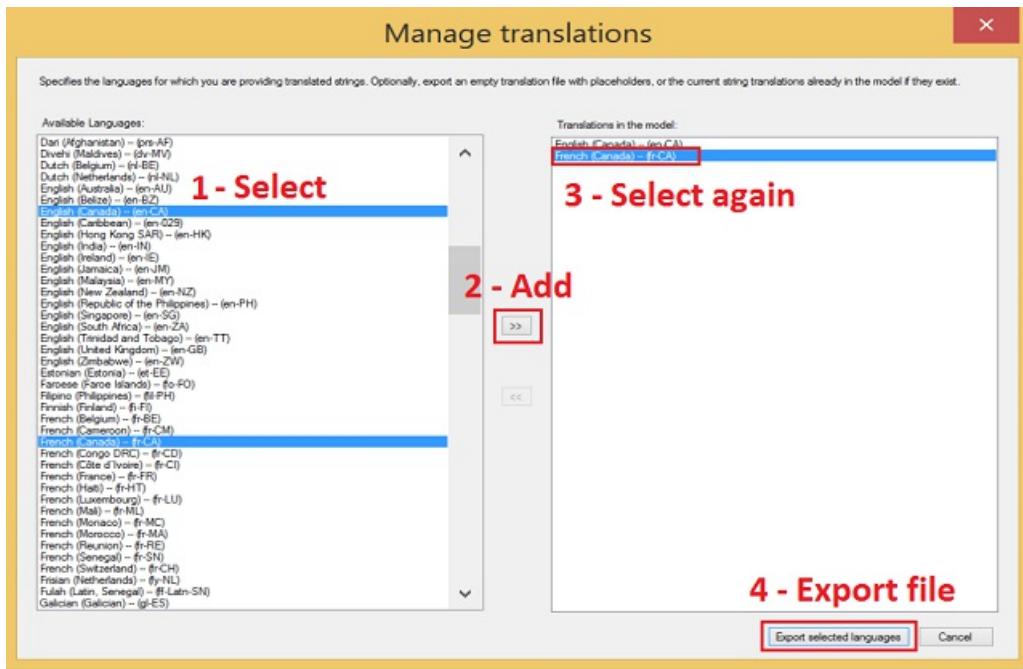

Create an empty translation file

Use Visual Studio with Analysis Services projects to add translations.

1. Click **Model > Translations > Manage Translations**.
2. Select the languages for which you are providing translations and then click **Add**.
3. Choose one or more languages from the list, depending on how you want to import the strings later.

Your translation file can include multiple languages, but you might find translation management easier if you create one translation file per language. The translation file you're creating now will be imported in its entirety later. To vary import options by language, each language needs to be in its own file.

4. Click **Export Language File**. Provide a file name and location.

Add translations

An empty JSON translation file includes metadata for a specific language translations. Translation placeholders for object names and descriptions are specified in the **Culture** section at the end of the model definition. Translations can be added for the following:

| | |
|-----------------------|--|
| translatedCaption | Table or column title that appears in any client application supporting visualizations of a Tabular model. |
| translatedDescription | Less common than captions, a description appears as model information in a modeling tool like SSDT. |

Don't delete any unspecified metadata from the file. It should match the file upon which it is based. Just add the strings you want, and then save the file.

Although it might look like something you should modify, the **referenceCulture** section contains the metadata in the default culture of the model. Any changes made to the **referenceCulture** section will not be read in during import and will be ignored.

The following example shows translated captions and description for the **DimProduct** and **DimCustomer** tables.

```

{
  "referenceCulture": {
    "name": "Tabular1200-AW_a249fce7-f7ea-40e0-8525-e9b3b2ce34b2",
    "id": "Tabular1200-AW_a249fce7-f7ea-40e0-8525-e9b3b2ce34b2",
    "model": ...
  },
  "cultures": [
    {
      "name": "fr-CA",
      "translations": {
        "model": {
          "name": "Model",
          "translatedCaption": "",
          "translatedDescription": "",
          "tables": [
            ...
            {
              "name": "DimCustomer",
              "translatedCaption": "Client",
              "translatedDescription": "Contient des renseignements sur les clients",
              "columns": ...
            },
            ...
            {
              "name": "DimProduct",
              "translatedCaption": "Produit",
              "translatedDescription": "Contient des informations de produit",
              "columns": ...
            },
            ...
          ]
        }
      }
    }
  ]
}

```

TIP

You can use any JSON editor to open the file, but we recommend using the JSON editor in Visual Studio so that you can also use the View Code command in Solution explorer to view the Tabular model definition in SSDT. To get the JSON editor, you need a [full version installation of Visual Studio 2015](#). The free Community edition includes the JSON editor.

Import a translation file

Translation strings that you import become a permanent part of the model definition. Once the strings are imported, the translation file is no longer referenced.

1. Click **Model > Translations > Import Translations**.
2. Find the translation file and then click **Open**.
3. Optionally, specify import options.

| | |
|------------------------------------|--|
| Overwrite existing translations | Replaces all existing captions or descriptions of the same language as the file being imported. |
| Ignore invalid objects | Specifies whether metadata discrepancies should be ignored or flagged as an error. |
| Write import results to a log file | Log files are saved to the project folder by default. The exact path to the file is provided after import concludes. The log file name is SSDT_Translations_Log_<timestamp>. |

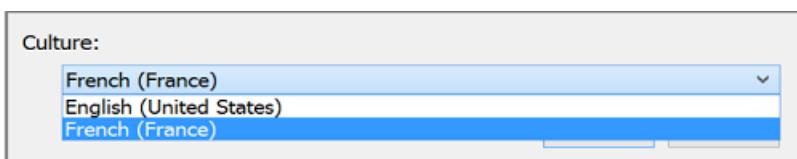

| | |
|---|---|
| <p>Back up translations to a JSON file before importing</p> | <p>Backs up an existing translation that matches the culture of the strings being imported. If the culture being imported is not present in the model, then the backup will be empty.</p> <p>If you need to restore this file later, you can replace the contents of the model.bim with this JSON file.</p> |
|---|---|

4. Click **Import**.
5. Optionally, if you generated a log file or backup, you can find the files in the project folder (for example, C:\Users\Documents\Visual Studio 2015\Projects\Tabular1200-AW\Tabular1200-AW).
6. To verify the import, follow these steps:
 - Right-click the **model.bim** file in Solution Explorer and choose **View Code**. Click **Yes** to close the design view and reopen **model.bim** in code view. If you installed a full version of Visual Studio, such as the free Community edition, the file opens in the built-in JSON editor.
 - Search for **Culture** or for a specific translated string to verify the strings you expect to see are actually there.

Connect using a locale identifier

This section describes an approach for validating the correct strings are returned from the model.

1. In Excel, connect to the Tabular model. This step assumes the model has been deployed. If the model only exists in the workspace, deploy it to an Analysis Services instance to complete the validation check.
- Alternatively, you can use the **Analyze in Excel** feature to connect to the model
2. In the Excel connection dialog box, choose the culture for which string translations exist in your model. Excel detects cultures defined in the model and populates the drop-down list accordingly.

When you create a PivotTable, you should see the translated table and column names.

Roles

10/25/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Roles, in tabular models, define member permissions for a model. Members of the role can perform actions on the model as defined by the role permission. Roles defined with read permissions can also provide additional security at the row-level by using row-level filters.

For SQL Server Analysis Services, roles contain user members by Windows username or by Windows group, and permissions (read, process, administrator). For Azure Analysis Services, users must be in your Azure Active Directory and usernames and groups specified must be by organizational email address or UPN.

IMPORTANT

When using SSDT to create roles and add organizational users to a tabular model project that will be deployed to Azure Analysis Services, use [Integrated workspace](#).

IMPORTANT

For users to connect to a deployed model by using a reporting client application, you must create at least one role with at least Read permission to which those users are members.

Information in this topic is meant for tabular model authors who define roles by using the Role Manager dialog box in SSDT. Roles defined during model authoring apply to the model workspace database. After a model database has been deployed, model database administrators can manage (add, edit, delete) role members by using SSMS.

Understanding roles

Roles are used in Analysis Services to manage model data access. There are two types of roles:

- The server role, a fixed role that provides administrator access to an Analysis Services server instance.
- Database roles, roles defined by model authors and administrators to control access to a model database and data for non-administrator users.

Roles defined for a tabular model are database roles. That is, the roles contain members consisting of users or groups that have specific permissions that define the action those members can take on the model database. A database role is created as a separate object in the database, and applies only to the database in which that role is created. Users and groups are included in the role by the model author, which, by default, has Administrator permissions on the workspace database server; for a deployed model, by an administrator.

Roles in tabular models can be further defined with row filters. Row filters use DAX expressions to define the rows in a table, and any related rows in the many direction, that a user can query. Row filters using DAX expressions can only be defined for the Read and Read and Process permissions. To learn more, see [Row Filters](#) later in this topic.

By default, when you create a new tabular model project, the model project does not have any roles. Roles can be defined by using the Role Manager dialog box in SSDT. When roles are defined during model authoring, they are applied to the model workspace database. When the model is deployed, the same roles are applied to

the deployed model. After a model has been deployed, members of the server role ([Analysis Services Administrator) and database administrators can manage the roles associated with the model and the members associated with each role by using SSMS.

Permissions

Each role has a single defined database permission (except for the combined Read and Process permission). By default, a new role will have the None permission. That is, once members are added to the role with the None permission, they cannot modify the database, run a process operation, query data, or see the database unless a different permission is granted.

A group or user can be a member of any number of roles, each role with a different permission. When a user is a member of multiple roles, the permissions defined for each role are cumulative. For example, if a user is a member of a role with the Read permission, and also a member of a role with None permission, that user will have Read permissions.

Each role can have one the following permissions defined:

| PERMISSIONS | DESCRIPTION | ROW FILTERS USING DAX |
|------------------|--|--|
| None | Members cannot make any modifications to the model database schema and cannot query data. | Row filters do not apply. No data is visible to users in this role |
| Read | Members are allowed to query data (based on row filters) but cannot see the model database in SSMS, cannot make any changes to the model database schema, and the user cannot process the model. | Row filters can be applied. Only data specified in the row filter DAX formula is visible to users. |
| Read and Process | Members are allowed to query data (based on row-level filters) and run process operations by running a script or package that contains a process command, but cannot make any changes to the database. Cannot view the model database in SSMS. | Row filters can be applied. Only data specified in the row filter DAX formula can be queried. |
| Process | Members can run process operations by running a script or package that contains a process command. Cannot modify the model database schema. Cannot query data. Cannot query the model database in SSMS. | Row filters do not apply. No data can be queried in this role |
| Administrator | Members can make modifications to the model schema and can query all data in the model designer, reporting client, and SSMS. | Row filters do not apply. All data can be queried in this role. |

Row filters

Row filters define which rows in a table can be queried by members of a particular role. Row filters are defined for each table in a model by using DAX formulas.

Row filters can be defined only for roles with Read and Read and Process permissions. By default, if a row filter is not defined for a particular table, members of a role that has Read or Read and Process permission can

query all rows in the table unless cross-filtering applies from another table.

Once a row filter is defined for a particular table, a DAX formula, which must evaluate to a TRUE/FALSE value, defines the rows that can be queried by members of that particular role. Rows not included in the DAX formula will not be queried. For example, for members of the Sales role, the Customers table with the following row filters expression, `=Customers[Country] = "USA"`, members of the Sales role, will only be able to see customers in the USA.

Row filters apply to the specified rows as well as related rows. When a table has multiple relationships, filters apply security for the relationship that is active. Row filters will be intersected with other row filters defined for related tables, for example:

| TABLE | DAX EXPRESSION |
|-----------------|--|
| Region | <code>=Region[Country] = "USA"</code> |
| ProductCategory | <code>=ProductCategory[Name] = "Bicycles"</code> |
| Transactions | <code>=Transactions[Year] = 2008</code> |

The net effect of these permissions on the Transactions table is that members will be allowed to query rows of data where the customer is in the USA, and the product category is bicycles, and the year is 2008. Users would not be able to query any transactions outside of the USA, or any transactions that are not bicycles, or any transactions not in 2008 unless they are a member of another role that grants these permissions.

You can use the filter, `=FALSE()`, to deny access to all rows for an entire table.

Dynamic security

Dynamic security provides a way to define row level security based on the user name of the user currently logged on or the CustomData property returned from a connection string. In order to implement dynamic security, you must include in your model a table with login (Windows user name) values for users as well as a field that can be used to define a particular permission; for example, a dimEmployees table with a login ID (domain\username) as well as a department value for each employee.

To implement dynamic security, you can use the following functions as part of a DAX formula to return the user name of the user currently logged on, or the CustomData property in a connection string:

| FUNCTION | DESCRIPTION |
|---|---|
| USERNAME Function (DAX) | Returns the domain\ username of the user currently logged on. |
| CUSTOMDATA Function (DAX) | Returns the CustomData property in a connection string. |

You can use the LOOKUPVALUE function to return values for a column in which the Windows user name is the same as the user name returned by the USERNAME function or a string returned by the CustomData function. Queries can then be restricted where the values returned by LOOKUPVALUE match values in the same or related table.

For example, using this formula:

```
= 'dimDepartmentGroup'[DepartmentGroupId]=LOOKUPVALUE('dimEmployees'[DepartmentGroupId], 'dimEmployees'[LoginId], USERNAME(), 'dimEmployees'[LoginId], 'dimDepartmentGroup'[DepartmentGroupId])
```

The LOOKUPVALUE function returns values for the dimEmployees[DepartmentId] column where the dimEmployees[LoginId] is the same as the LoginID of the user currently logged on, returned by USERNAME, and values for dimEmployees[DepartmentId] are the same as values for dimDepartmentGroup[DepartmentId].

The values in DepartmentId returned by LOOKUPVALUE are then used to restrict the rows queried in the dimDepartment table, and any tables related by DepartmentId. Only rows where DepartmentId are also in the values for the DepartmentId returned by LOOKUPVALUE function are returned.

dimEmployees

| LASTNAME | FIRSTNAME | LOGINID | DEPARTMENTNAME | DEPARTMENTID |
|------------------|-----------|-------------------------|-----------------|--------------|
| Brown | Kevin | Adventure-works\kevin0 | Marketing | 7 |
| Bradley | David | Adventure-works\david0 | Marketing | 7 |
| Dobney | JoLynn | Adventure-works\JoLynn0 | Production | 4 |
| Baretto DeMattos | Paula | Adventure-works\Paula0 | Human Resources | 2 |

dimDepartment

| DEPARTMENTID | DEPARTMENTNAME |
|--------------|--------------------------------------|
| 1 | Corporate |
| 2 | Executive General and Administration |
| 3 | Inventory Management |
| 4 | Manufacturing |
| 5 | Quality Assurance |
| 6 | Research and Development |
| 7 | Sales and Marketing |

Testing roles

When authoring a model project, you can use the Analyze in Excel feature to test the efficacy of the roles you have defined. From the **Model** menu in the model designer, when you click **Analyze in Excel**, before Excel opens, the **Choose Credentials and Perspective** dialog box appears. In this dialog, you can specify the current username, a different username, a role, and a perspective with which you will use to connect to the workspace model as a data source. To learn more, see [Analyze in Excel](#).

Create and manage roles

10/25/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Roles, in tabular models, define member permissions for a model. Roles are defined for a model project by using the Role Manager dialog box in Visual Studio with Analysis Services projects.

IMPORTANT

If you're deploying your project to Azure Analysis Services, use **Integrated Workspace** as your workspace database. To learn more, see [Workspace database](#).

The tasks in this article describe how to create and manage roles during model authoring by using the Role Manager dialog box in Visual Studio with Analysis Services projects.

Tasks

To create, edit, copy, and delete roles, you will use the **Role Manager** dialog box. To view the **Role Manager** dialog box, in Visual Studio with Analysis Services projects, click the **Model** menu, and then click **Role Manager**.

To create a new role

1. In Visual Studio with Analysis Services projects, click the **Model** menu, and then click **Role Manager**.
2. In the **Role Manager** dialog box, click **New**.

A new highlighted role is added to the Roles list.

3. In the **Roles** list, in the **Name** field, type a name for the role.

By default, the name of the default role will be incrementally numbered for each new role. It is recommended you type a name that clearly identifies the member type, for example, Finance Managers or Human Resources Specialists.

4. In the **Permissions** field, click the down arrow and then select one of the following permission types:

| PERMISSION | DESCRIPTION |
|-------------------------|---|
| None | Members cannot make any modifications to the model schema and cannot query data. |
| Read | Members are allowed to query data (based on row filters) but cannot make any changes to the model schema. |
| Read and Process | Members are allowed to query data (based on row-level filters) and run Process and Process All operations, but cannot make any changes to the model schema. |
| Process | Members can run Process and Process All operations. Cannot modify the model schema and cannot query data. |

| PERMISSION | DESCRIPTION |
|----------------------|--|
| Administrator | Members can make modifications to the model schema and can query all data. |

5. To enter a description for the role, click the **Description** field, and then type a description.
6. If the role you are creating has Read or Read and Process permission, you can add row filters using a DAX formula. To add row filters, click the **Row Filters** tab, then select a table, then click the **DAX Filter** field, and then type a DAX formula.
7. To add members to the role, click the **Members** tab, and then click **Add**.

NOTE

Role members can also be added to a deployed model by using SQL Server Management Studio. For more information, see [Manage Roles by using SSMS](#).

8. In the **Select Users or Groups** dialog box, enter Windows user or Windows group objects as members.
9. Click **Ok**.

[CUSTOMDATA Function \(DAX\)](#)

Object-level security

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Data model security starts with effectively implementing [roles](#) and row-level filters to define user permissions on data model objects and data. Beginning with tabular 1400 models, you can also define object-level security, which includes table-level security and column-level security in the [Roles object](#).

Table-level security

With table-level security, you can not only restrict access to table data, but also sensitive table names, helping prevent malicious users from discovering if a table exists.

Table-level security is set in the JSON-based metadata in the Model.bim, [Tabular Model Scripting Language \(TMSL\)](#), or [Tabular Object Model \(TOM\)](#). Set the **metadataPermission** property of the **tablePermissions** class in the [Roles object](#) to **none**.

In this example, the metadataPermission property of the tablePermissions class for the Product table is set to none:

```
"roles": [
  {
    "name": "Users",
    "description": "All allowed users to query the model",
    "modelPermission": "read",
    "tablePermissions": [
      {
        "name": "Product",
        "metadataPermission": "none"
      }
    ]
  }
]
```

Column-level security

Similar to table-level security, with column-level security you can not only restrict access to column data, but also sensitive column names, helping prevent malicious users from discovering a column.

Column-level security is set in the JSON-based metadata in the Model.bim, [Tabular Model Scripting Language \(TMSL\)](#), or [Tabular Object Model \(TOM\)](#). Set the **metadataPermission** property of the **columnPermissions** class in the [Roles object](#) to **none**.

In this example, the metadataPermission property of the columnPermissions class for the Base Rate column in the Employees table is set to none:

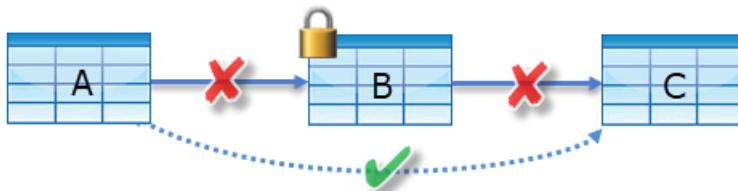

```

"roles": [
  {
    "name": "Users",
    "description": "All allowed users to query the model",
    "modelPermission": "read",
    "tablePermissions": [
      {
        "name": "Employee",
        "columnPermissions": [
          {
            "name": "Base Rate",
            "metadataPermission": "none"
          }
        ]
      }
    ]
  }
]

```

Restrictions

- Table-level security cannot be set for a model if it breaks a relationship chain. An error is generated at design time. For example, if there are relationships between tables A and B, and B and C, you cannot secure table B. If table B is secured, a query on table A cannot transit the relationships between table A and B, and B and C. In this case, a separate relationship could be configured between tables A and B.

- Row-level security and object-level security cannot be combined from different roles because it could introduce unintended access to secured data. An error is generated at query time for users who are members of such a combination of roles.
- Dynamic calculations (measures, KPIs, DetailRows) are automatically restricted if they reference a secured table or column. While there is no mechanism to explicitly secure a measure, it is possible to implicitly secure a measure by updating the expression to refer to a secured table or column.
- Relationships that reference a secured column work provided the table the column is in is not secured.

String storage and collation in tabular models

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Strings (text values) are stored in a highly compressed format in tabular models; because of this compression, you can get unexpected results when you retrieve entire or partial strings. Also, because string locale and collations are inherited hierarchically from the closest parent object, if the string language is not explicitly defined, the locale and collation of the parent can affect how each string is stored and whether the string is unique or conflated with similar strings as defined by the parent collation.

This article describes the mechanism by which strings are compressed and stored, and provides examples of how collation and language affect the results of text formulas in tabular models.

Storage

In tabular models all data is highly compressed to better fit in memory. As a consequence, all strings that can be considered lexically equivalent are stored only once. The first instance of the string is used as the canonical representation and thereafter each equivalent string is indexed to the same compressed value as the first occurrence.

The key question is: what constitutes a lexically equivalent string? Two strings are considered lexically equivalent if they can be considered as the same word. For example, in English when you search for the word **violin** in a dictionary, you might find the entry **Violin** or **violin**, depending on the editorial policy of the dictionary, but generally you consider both words equivalent, and disregard the difference in capitalization. In a tabular model, the factor that determines whether two strings are lexically equivalent is not editorial policy or even user preference, but the locale and collation order assigned to the column.

Therefore, the decision of whether uppercase and lowercase letters should be handled as the same or different depends on the collation and locale. For any particular word within that locale, the first occurrence of the word that is found within a particular column therefore serves as the canonical representation of that word and that string is stored in uncompressed format. All other strings are tested against the first occurrence, and if they match the equivalence test, they are assigned to the compressed value of the first occurrence. Later, when the compressed values are retrieved they are represented using the uncompressed value of the first occurrence of the string.

An example will help to clarify how this works. The following column "Classification - English" was extracted from a table that contains information about plants and trees. For each plant (the names of the plants are not shown here) the classification column shows the general category of plant.

| CLASSIFICATION - ENGLISH |
|--------------------------|
| trEE |
| PIAnT |
| TREE |
| PLANT |
| Plant |

CLASSIFICATION - ENGLISH

Tree

plant

tReE

tree

pLaNt

tREE

Perhaps the data came from many different sources, and so the casing and use of accents was inconsistent, and the relational database stored those differences as is. But in general the values are either **Plant** or **Tree**, just with different casing.

When these values are loaded into a tabular model that uses the default collation and sorting order for American English, case is not important, so only two values would be stored for the entire column:

CLASSIFICATION - ENGLISH

trEE

PIAnT

If you use the column, **Classification - English**, in your model, wherever you display plant classification you will see not the original values, with their various uses of upper and lower case, but only the first instance. The reason is that all the uppercase and lowercase variants of **tree** are considered equivalent in this collation and locale; therefore, only one string was preserved and the first instance of that string that is encountered by the system is the one that is saved.

WARNING

You might decide that you want to define which string will be the first to store, according to what you consider correct, but this could be very hard to do. There is no simple way to determine in advance which row should be processed first by the engine, given that all values are considered to be the same. Instead, if you need to set the standard value, you should cleanse all your strings before loading the model.

Locale and Collation Order

When comparing strings (text values), what defines equivalence is normally the cultural aspect of how such strings are interpreted. In some cultures an accent or the capitalization of a character can completely change the meaning of the string; therefore, typically such differences are considered when determining equivalency for any particular language or region.

Usually, when you use your computer it is already configured to match your own cultural expectations and linguistic behavior, and string operations such as sorting and comparing text values behaves as you would expect. The settings that control language-specific behavior are defined through the **Locale and Regional** settings in Windows. Applications read those settings and change their behavior accordingly. In some cases, an application might have a feature that allows you to change the cultural behavior of the application or the way in which strings are compared.

When you are creating a tabular model database, by default the database inherits these cultural and linguistic settings in the form of a language identifier and collation.

- The language identifier defines the character set you want to use for your strings according to your culture.
- The collation defines the ordering of the characters and their equivalence.

It is important to note that a language identifier not only identifies a language but, also the country or region where the language is used. Each language identifier also has a default collation specification. For more information about language identifiers, see [Locale IDs Assigned by Microsoft](#). You can use the LCID Dec column to get the correct ID when manually inserting a value. For more information about the SQL concept of collations, see [COLLATE \(Transact-SQL\)](#). For information about the collation designators and the comparison styles for Windows collation names, see [Windows Collation Name \(Transact-SQL\)](#). The topic, [SQL Server Collation Name \(Transact-SQL\)](#), maps the Windows collation names to the names used for SQL.

Once your tabular model database has been created, all new objects in the model will inherit the language and collation attributes from the database attributes. This is true for all objects. The inheritance path begins at the object, looks at the parent for any language and collation attributes to inherit, and if none are found, continues to the top and finds the language and collation attributes at the database level. In other words, if you do not specify the language and collation attributes for an object, by default, the object inherits the attributes of its closest parent.

For columns, the language and collation attributes are inherited at creation, according to the following rules:

1. The parent dimension object is searched for language and collation attributes. If both values exist, they are copied to the column attributes; if only one exists, the other is inferred from the existing one and both are assigned; if none exist, move to next step.
2. The database object is searched using the same process described in Step 1 for dimensions; if no attributes are found, move to the next step.
3. The server object is searched using the same process described in Step 1 for dimensions; if no attributes are found, the column uses the Windows language identifier and infers the collation attribute from that value.

It is important to note that typically the language identifier and collation order in the source database has little to no effect on how values are stored in the tabular model column. The exception is if the source database transforms or filters the requested values.

Tabular model solution deployment

10/22/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After authoring a tabular model project, you must deploy it in order for users to browse the model by using a reporting client application. This article describes the various properties and methods you can use when deploying tabular model solutions in your environment.

Benefits

Deploying a tabular model creates a model database in a test, staging, or production environment. Users can then connect to the deployed model through a .bism connection file in Sharepoint or by using a data connection directly from reporting client applications such as Microsoft Excel, Power View, or a custom application. The model workspace database, created when you create a new tabular model project in Visual Studio with Analysis Services projects, and used to author the model will remain on the workspace server instance, allowing you to make changes to the model project and then re-deploying to the test, staging, or production environment when necessary.

Deploying a tabular model from Visual Studio

Deploying is a simple process; however, certain steps must be taken to ensure your model is deployed to the correct Analysis Services instance and with the correct configuration options.

Tabular models are defined with several deployment-specific properties. When you deploy, a connection to the Analysis Services instance specified in the **Server** property is established. A new model database with the name specified in the **Database** property is then created on that instance, if one does not already exist. Metadata from the model project's Model.bim file is used to configure objects in the model database on the deployment server. With the **Processing Option**, you can specify whether or not just the model metadata is deployed, creating the model database, or if **Default** or **Full** is specified, impersonation credentials used to connect to data sources are passed in-memory from the model workspace database to the deployed model database. Analysis Services then runs processing to populate data into the deployed model. Once the deployment process is complete, the model can then be connected to by client applications using a data connection or by using an .bism connection file in SharePoint.

Deployment properties

The project deployment options and deployment server properties specify how and where a model is deployed to a staging or production Analysis Services environment. While default property settings are defined for all model projects, depending on your particular deployment requirements, you can change these property settings for each project. For more information about setting default deployment properties, see [Configure default data modeling and deployment properties](#).

Deployment options properties

Deployment options properties include the following:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------|-----------------|-------------|
|----------|-----------------|-------------|

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------|-----------------|--|
| Processing Option | Default | <p>This property specifies the type of processing required when changes to objects are deployed. This property has the following options:</p> <p>Default - This setting specifies Analysis Services will determine the type of processing required. Unprocessed objects will be processed, and if required, recalculating attribute relationships, attribute hierarchies, user hierarchies, and calculated columns. This setting generally results in a faster deployment time than using the Full processing option.</p> <p>Do Not Process - This setting specifies only the metadata will be deployed. After deploying, it may be necessary to run a process operation on the deployed model to update and recalculate data.</p> <p>Full - This setting specifies that both the metadata is deployed and a process full operation is performed. This assures that the deployed model has the most recent updates to both metadata and data.</p> |
| Transactional Deployment | False | <p>This property specifies whether or not the deployment is transactional. By default, the deployment of all or changed objects is not transactional with the processing of those deployed objects. Deployment can succeed and persist even though processing fails. You can change this to incorporate deployment and processing in a single transaction.</p> |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------|------------------|---|
| Query Mode | In-Memory | <p>This property specifies the mode in which the source from which query results are returned is running in In-Memory (cached) mode or in DirectQuery mode. This property has the following options:</p> <ul style="list-style-type: none"> DirectQuery - This setting specifies all queries to the model should use the relational data source only. DirectQuery with In-Memory - This setting specifies, by default, queries should be answered by using the relational source, unless otherwise specified in the connection string from the client. In-Memory - This setting specifies queries should be answered by using the cache only. In-Memory with DirectQuery - This setting specifies, by default, queries should be answered by using the cache, unless otherwise specified in the connection string from the client. <p>For more information, see DirectQuery Mode.</p> |

Deployment server properties

Deployment Server properties include the following:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---|------------------|--|
| Server

Set when the project is created. | localhost | This property, set when the project is created, specifies the Analysis Services instance by name to which the model will be deployed. By default, the model will be deployed to the default instance of Analysis Services on the local computer. However, you can change this setting to specify a named instance on the local computer or any instance on any remote computer on which you have permission to create Analysis Services objects. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|------------------|--|--|
| Edition | The same edition as the instance in which the Workspace Server is located. | This property specifies the edition of the Analysis Services server to which the model will be deployed. The server edition defines various features that can be incorporated into the project. By default, the edition will be of the local Analysis Services server. If you specify a different Analysis Services server, for example, a production Analysis Services server, be sure to specify the edition of that Analysis Services server. |
| Database | <projectname> | <p>This property specifies the name of the Analysis Services database in which model objects will be instantiated upon deployment. This name will also be specified in a reporting client data connection or an .bism data connection file.</p> <p>You can change this name at any time when you are authoring the model. If you change the name after you have deployed the model, changes that you have made after deployment will not affect the model that you previously deployed. For example, if you open a solution named TestDB and deploy your solution with the default model Database name Model, and then modify the solution and renamed the model Database Sales, the instance of Analysis Services the solutions were deployed to will display separate databases, one named Model and one named Sales.</p> |
| Cube Name | Model | This property specifies the cube name as shown in client tools (such as Excel) and AMO (Analysis Management Objects). |

DirectQuery options properties

Deployment Options properties include the following:

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|----------|-----------------|-------------|
|----------|-----------------|-------------|

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-------------------------------|-----------------|--|
| Impersonation Settings | Default | <p>This property specifies the impersonation settings used when a model running in DirectQuery mode connects to data sources. Impersonation credentials are not used when querying the in-memory cache. This property setting has the following options:</p> <p>Default - This setting specifies Analysis Services will use the option specified on the Impersonation Information page when the data source connection was created by using the Table Import Wizard.</p> <p>ImpersonateCurrentUser - This setting specifies the user account of the user currently logged on will be used when connecting to all data sources.</p> |

Deployment methods

There are several methods you can use to deploy a tabular model project. Most of the deployment methods that can be used for other Analysis Services projects, such as multidimensional, can also be used to deploy tabular model projects.

| METHOD | DESCRIPTION | LINK |
|---|---|---|
| Deploy command in SQL Server Data Tools | <p>The Deploy command provides a simple and intuitive method to deploy a tabular model project from the Visual Studio with Analysis Services projects authoring environment.</p> <p>Caution This method should not be used to deploy to production servers. Using this method can overwrite certain properties in an already deployed, existing model; for example, when using scripts or SSMS to modify properties.</p> | Deploy From SQL Server Data Tools |
| Analysis Management Objects (AMO) Automation | AMO provides a programmatic interface to the complete command set for Analysis Services, including commands that can be used for solution deployment. As an approach for solution deployment, AMO automation is the most flexible, but it also requires a programming effort. A key advantage to using AMO is that you can use SQL Server Agent with your AMO application to run deployment on a preset schedule. | Developing with Analysis Management Objects (AMO) |

| METHOD | DESCRIPTION | LINK |
|---------------------------|---|--|
| XMLA | <p>Use SQL Server Management Studio to generate an XMLA script of the metadata of an existing Analysis Services database, and then run that script on another server to recreate the initial database. XMLA scripts are easily formed in SQL Server Management Studio by defining the deployment process, then codifying it and saving it in an XMLA script. Once you have the XMLA script in a saved file, you can easily run the script according to a schedule, or embed the script in an application that connects directly to an instance of Analysis Services.</p> <p>You can also run XMLA Scripts on a preset basis using SQL Server Agent, but you do not have the same flexibility with XMLA Scripts as with AMO. AMO provides a larger breadth of functionality by hosting the complete spectrum of administrative commands.</p> | Deploy Model Solutions Using XMLA |
| Deployment Wizard | <p>Use the Deployment Wizard to use the XMLA output files generated by an Analysis Services project to deploy the project's metadata to a destination server. With the Deployment Wizard, you can deploy directly from the Analysis Services file, as created by the output directory by project build.</p> <p>The primary advantage of using the Analysis Services Deployment Wizard is convenience. Just as you can save an XMLA script for use later in SQL Server Management Studio, you can save Deployment Wizard scripts. The Deployment Wizard can be run both interactively and at the command prompt via the Deployment Utility.</p> | Deploy Model Solutions Using the Deployment Wizard |
| Deployment Utility | The Deployment utility lets you start the Analysis Services deployment engine from a command prompt. | Deploy Model Solutions with the Deployment Utility |

| METHOD | DESCRIPTION | LINK |
|------------------------------------|---|---|
| Synchronize Database Wizard | <p>Use the Synchronize Database Wizard to synchronize the metadata and data between any two Analysis Services databases.</p> <p>The Synchronize Wizard can be used to copy both data and metadata from a source server to a destination server. If the destination server does not have a copy of the database that you want to deploy, a new database is copied to the destination server. If the destination server already has a copy of the same database, the database on the destination server is updated to use the metadata and data of the source database.</p> | Synchronize Analysis Services Databases |
| Backup and Restore | <p>Backup offers the simplest approach to transferring Analysis Services databases. From the Backup dialog box, you can set the options configuration, and then you can run the backup from the dialog box itself. Or, you can create a script that can be saved and run as frequently as required.</p> <p>Backup and restore is not used as frequently as the other deployment methods, but is a way to quickly complete a deployment with minimal infrastructure requirements.</p> | Backup and Restore of Analysis Services Databases |

Configuring the deployment server and connecting to a deployed model

After a model has been deployed, there are additional considerations for securing model data access, backups, and processing operations that can be configured on the Analysis Services server by using SQL Server Management Studio. While these properties and configuration settings are outside the scope of this topic, they are, nonetheless, very important in assuring your deployed model data is secure, kept up to date, and provide a valuable data analysis resource for users in your organization.

After a model has been deployed, and optional server settings configured, the model can be connected to by reporting client applications and used to browse and analyze the model metadata. Connecting to a deployed model database from client applications is outside the scope of this topic.

Deploy From Visual Studio

10/22/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use the tasks in this article to deploy a tabular model solution by using the Deploy command in Visual Studio.

Configure deployment options and deployment server properties

Before you deploy your tabular model solution, you must first specify the Deployment Options and Deployment Server properties. For more information about deployment properties and settings, see [Tabular model solution deployment](#).

To configure options and properties

1. In **Solution Explorer**, right-click the project name, and then click **Properties**.
2. In the <project name> **Properties** dialog, in **Deployment Options**, specify property settings if different from the default settings.

NOTE

For models in cached mode, **Query Mode** is always **In-Memory**.

NOTE

You cannot specify **Impersonation Settings** for models in DirectQuery mode.

3. In **Deployment Server**, specify the **Server** (name), **Edition**, **Database** (name), and **Cube Name** property settings, if different from the default settings, and then click **OK**.

NOTE

You can also specify the Default Deployment Server property setting so any new projects you create will automatically be deployed to the specified server. For more information, see [Configure default data modeling and deployment properties](#).

Deploy a tabular model

To deploy a tabular model

- In Visual Studio, on the **Build** menu, click **Deploy <project name>**.

The **Deploy** dialog box will appear and indicate the status of the metadata deployment and the processing (unless Processing Option property is set to Do Not Process) of each table included in the model. After the deployment process is complete, use SSMS to connect to the Analysis Services instance and verify the new model database object has been created or use a client reporting application to connect to the deployed model.

Deploy Status

The **Deploy** dialog box enables you to monitor the progress of a Deploy operation. A deploy operation can also be stopped.

Status

Indicates whether the Deploy operation was successful or not.

Details

Lists the metadata items that were deployed, the status for each metadata item, and provides a message of any issues.

Stop Deploy

Click to halt the Deploy operation. This option is useful if the Deploy operation is taking too long, or if there are too many errors.

NOTE

For DirectQuery models, if the model contains calculated items, calculated columns, calculated tables, after being deployed you must perform a **Process Recalc** on the database. To learn more about processing a model database from SSMS, see [Process Database, Table, or Partition](#).

Process Database, Table, or Partition (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The tasks in this topic describe how to process a tabular model database, table, or partitions manually by using the **Process <object>** dialog box in SQL Server Management Studio.

To process a database

1. In SQL Server Management Studio, right-click on the database you want to process, and then click **Process Database**.
2. In the **Process Database** dialog box, in the **Mode** listbox, select one of the following process modes:

| MODE | DESCRIPTION |
|------------------------|---|
| Process Default | Detects the process state of database objects, and performs processing necessary to deliver unprocessed or partially processed objects to a fully processed state. Data for empty tables and partitions is loaded; hierarchies, calculated columns, and relationships are built or rebuilt (recalculated). |
| Process Full | Processes a database and all the objects that it contains. When Process Full is run for an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object. This option requires the most resources. |
| Process Clear | Removes all data from database objects. |
| Process Recalc | Updates and recalculates hierarchies, relationships, and calculated columns. |

3. In the **Process** checkbox column, select the partitions you want to process with the selected mode, and then click **Ok**.

To process a table

1. In SQL Server Management Studio, in the tabular model database which contains the table you want to process, expand the **Tables** node, then right-click on the table you want to process, and then click **Process Table**.
2. In the **Process Table** dialog box, in the **Mode** listbox, select one of the following process modes:

| MODE | DESCRIPTION |
|------|-------------|
|------|-------------|

| MODE | DESCRIPTION |
|------------------------|---|
| Process Default | Detects the process state of a table object, and performs processing necessary to deliver unprocessed or partially processed objects to a fully processed state. Data for empty tables and partitions is loaded; hierarchies, calculated columns, and relationships are built or rebuilt (recalculated). |
| Process Full | Processes a table object and all the objects that it contains. When Process Full is run for an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object. This option requires the most resources. |
| Process Data | Load data into a table without rebuilding hierarchies or relationships or recalculating calculated columns and measures. |
| Process Clear | Removes all data from a table and any table partitions. |
| Process Defrag | Defragments the auxiliary table indexes. |

3. In the table checkbox column, verify the table and optionally select any additional tables you want to process, and then click **Ok**.

To process one or more partitions

1. In SQL Server Management Studio, right-click on the table that has the partitions you want to process, and then click **Partitions**.
2. In the **Partitions** dialog box, in **Partitions**, click the Process button.
3. In the **Process Partition** dialog box, in the **Mode** listbox, select one of the following process modes:

| MODE | DESCRIPTION |
|------------------------|--|
| Process Default | Detects the process state of a partition object, and performs processing necessary to deliver unprocessed or partially processed partition objects to a fully processed state. Data for empty tables and partitions is loaded; hierarchies, calculated columns, and relationships are built or rebuilt (recalculated). |
| Process Full | Processes a partition object and all the objects that it contains. When Process Full is run for an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object. |
| Process Data | Load data into a partition or a table without rebuilding hierarchies or relationships or recalculating calculated columns and measures. |
| Process Clear | Removes all data from a partition. |

| MODE | DESCRIPTION |
|--------------------|---|
| Process Add | Incrementally update partition with new data. |

4. In the **Process** checkbox column, select the partitions you want to process with the selected mode, and then click **Ok**.

[Tabular Model Partitions](#)

[Create and Manage Tabular Model Partitions](#)

Manage roles by using SSMS

10/25/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can create, edit, and manage roles for a deployed tabular model by using SQL Server Management Studio.

Caution

Re-deploying a tabular model project with roles defined by using Role Manager in Visual Studio will overwrite roles defined in a deployed tabular model.

Caution

Using SQL Server Management Studio to manage a tabular model workspace database while the model project is open in Visual Studio may cause the Model.bim file to become corrupted. When creating and managing roles for a tabular model workspace database, use Role Manager in Visual Studio.

To create a new role

1. In SQL Server Management Studio, expand the tabular model database for which you want to create a new role, then right click on **Roles**, and then click **New Role**.
2. In the **Create Role** dialog box, in the Select a page window, click **General**.
3. In the general settings window, in the **Name** field, type a name for the role.

By default, the name of the default role will be incrementally numbered for each new role. It is recommended you type a name that clearly identifies the member type, for example, Finance Managers or Human Resources Specialists.

4. In **Set the database permissions for this role**, select one of the following permissions options:

| PERMISSION | DESCRIPTION |
|-------------------------------------|--|
| Full control (Administrator) | Members can make modifications to the model schema and can view all data. |
| Process database | Members can run Process and Process All operations. Cannot modify the model schema and cannot view data. |
| Read | Members are allowed to view data (based on row filters) but cannot make any changes to the model schema. |

5. In the **Create Role** dialog box, in the Select a page window, click **Membership**.
6. In the membership settings window, click **Add**, and then in the **Select Users or Groups** dialog box, add the Windows users or groups you want to add as members.
7. If the role you are creating has Read permissions, you can add row filters for any table using a DAX formula. To add row filters, in the **Role Properties - <rolename>** dialog box, in **Select a page**, click on **Row Filters**.
8. In the row filters window, select a table, then click on the **DAX Filter** field, and then in the **DAX Filter - <tablename>** field, type a DAX formula.

NOTE

The DAX Filter - <tablename> field does not contain an AutoComplete query editor or insert function feature. To use AutoComplete when writing a DAX formula, you must use a DAX formula editor in Visual Studio.

9. Click **Ok** to save the role.

To copy a role

1. In SQL Server Management Studio, expand the tabular model database that contains the role you want to copy, then expand **Roles**, then right click on the role, and then click **Duplicate**.

To edit a role

- In SQL Server Management Studio, expand the tabular model database that contains the role you want to edit, then expand **Roles**, then right click on the role, and then click **Properties**.

In the **Role Properties** <rolename> dialog box, you can change permissions, add or remove members, and add/edit row filters.

To delete a role

- In SQL Server Management Studio, expand the tabular model database that contains the role you want to delete, then expand **Roles**, then right click on the role, and then click **Delete**.

[Roles](#)

Tabular model partitions

10/25/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Partitions divide a table into logical parts. Each partition can then be processed (Refreshed) independent of other partitions. Partitions defined for a model during model authoring are duplicated in a deployed model. Once deployed, you can manage those partitions and create new partitions by using the **Partitions** dialog box in SQL Server Management Studio or by using a script. Information provided in this topic describes partitions in a deployed tabular model database. For more information about creating and managing partitions during model authoring, see [Partitions](#).

Benefits

Effective model design utilizes partitions to eliminate unnecessary processing and subsequent processor load on Analysis Services servers, while at the same time, making certain that data is processed and refreshed often enough to reflect the most recent data from data sources.

For example, a tabular model can have a Sales table which includes sales data for the current 2011 fiscal year and each of the previous fiscal years. The model's Sales table has the following three partitions:

| PARTITION | DATA FROM |
|----------------|---|
| Sales2011 | Current fiscal year |
| Sales2010-2001 | Fiscal years 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010 |
| SalesOld | All fiscal years prior to the last ten years. |

As new sales data is added for the current 2011 fiscal year; that data must be processed daily to accurately be reflected in current fiscal year sales data analysis, thus the Sales2011 partition is processed nightly.

There is no need to process data in the Sales2010-2001 partition nightly; however, because sales data for the previous ten fiscal years can still occasionally change because of product returns and other adjustments, it must still be processed regularly, thus data in the Sales2010-2001 partition is processed monthly. Data in the SalesOld partition never changes therefore only processed annually.

When entering the 2012 fiscal year, a new Sales2012 partition is added to the mode's Sales table. The Sales2011 partition can then be merged with the Sales2010-2001 partition and renamed to Sales2011-2002. Data from the 2001 fiscal year is eliminated from the new Sales2011-2002 partition and moved into the SalesOld partition. All partitions are then processed to reflect changes.

How you implement a partition strategy for your organization's tabular models will largely be dependent on your particular model data processing needs and available resources.

Permissions

In order to create, manage, and process partitions in SQL Server Management Studio, you must have the appropriate Analysis Services permissions defined in a security role. Each security role has one of the following permissions:

| PERMISSION | ACTIONS |
|---------------|--|
| Administrator | Read, process, create, copy, merge, delete |
| Process | Read, process |
| Read Only | Read |

Parallel processing

Analysis Services includes parallel processing for tables with two or more partitions, increasing processing performance. There are no configuration settings for parallel processing (see notes). Parallel processing occurs by default when you Process Table or you select multiple partitions for the same table and Process. You can still choose to process a table's partitions independently.

NOTE

To specify whether refresh operations run sequentially or in parallel, you can use the **maxParallelism** property option with the [Sequence command \(TMSL\)](#).

NOTE

If re-encoding is detected, parallel processing can cause increased use of system resources. This is because multiple partition operations need to be interrupted and re-started with the new encoding in-parallel.

Processing partitions

Partitions can be processed (refreshed) independent of other partitions by using the **Partitions** dialog box in Management Studio or by using a script. Processing has the following options:

| MODE | DESCRIPTION |
|-----------------|--|
| Process Default | Detects the process state of a partition object, and performs processing necessary to deliver unprocessed or partially processed partition objects to a fully processed state. Data for empty tables and partitions is loaded; hierarchies, calculated columns, and relationships are built or rebuilt. |
| Process Full | Processes a partition object and all the objects that it contains. When Process Full is run for an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object. |
| Process Data | Load data into a partition or a table without rebuilding hierarchies or relationships or recalculating calculated columns and measures. |
| Process Clear | Removes all data from a partition. |
| Process Add | Incrementally update partition with new data. |

[Create and manage tabular model partitions](#)

[Process tabular model partitions](#)

Create and manage tabular model partitions

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Partitions divide a table into logical parts. Each partition can then be processed (Refreshed) independent of other partitions. Partitions defined for a model during model authoring are duplicated in a deployed model. Once deployed, you can manage those partitions by using the **Partitions** dialog box in SQL Server Management Studio or by using a script. Tasks provided in this topic describe how to create and manage partitions for a deployed model.

NOTE

Partitions in tabular models created at the 1400 compatibility level are defined using an M query statement. To learn more, see [M Reference](#).

Tasks

To create and manage partitions for a deployed tabular model database, you will use the **Partitions** dialog box in SQL Server Management Studio. To view the **Partitions** dialog box, in SQL Server Management Studio, right-click on a table, and then click **Partitions**.

To create a new partition

1. In the **Partitions** dialog box, click the **New** button.
2. In **Partition Name**, type a name for the partition. By default, the name of the default partition will be incrementally numbered for each new partition.
3. In **Query Statement**, type or paste a SQL or M query statement that defines the columns and any clauses you want to include in the partition into the query window.
4. To validate the statement, click **Check Syntax**.

To copy a partition

1. In the **Partitions** dialog box, in the **Partitions** list, select the partition you want to copy, and then click the **Copy** button.
2. In **Partition Name**, type a new name for the partition.
3. In **Query Statement**, edit the query statement.

To merge two or more partitions

- In the **Partitions** dialog box, in the **Partitions** list, use Ctrl+click to select the partitions you want to merge, and then click the **Merge** button.

IMPORTANT

Merging partitions does not update the partition metadata. You must edit the SQL or M statement for the resulting partition to make sure processing operations process all data in the merged partition.

To delete a partition

- In the **Partitions** dialog box, in the **Partitions** list, select the partition you want to delete, and then click the **Delete** button.

[Tabular Model Partitions](#)

[Create and Manage Tabular Model Partitions](#)

Connect to a tabular model database

10/25/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you build a tabular model and deploy it to an Analysis Services tabular mode server, you need to set permissions that make it available to client applications. This article explains how to set permissions and how to connect to a database from client applications.

NOTE

By default, remote connections to Analysis Services are not available until you configure the firewall. Be sure that you have opened the appropriate port if you are configuring a named or default instance for client connections. For more information, see [Configure the Windows Firewall to Allow Analysis Services Access](#).

User permissions on the database

Users who connect to tabular databases must have membership in a database role that specifies Read access.

Roles, and sometimes role membership, are defined when a model is authored in Visual Studio with Analysis Services projects, or for deployed models, by using SQL Server Management Studio. For more information about creating roles by using Role Manager in Visual Studio with Analysis Services projects, see [Create and Manage Roles](#).

Caution

Re-deploying a tabular model project with roles defined by using Role Manager in Visual Studio with Analysis Services projects will overwrite roles defined in a deployed tabular model.

Administrative permissions on the server

For organizations that use SharePoint for hosting Excel workbooks or Reporting Services reports, additional configuration is required to make tabular model data available to SharePoint users. If you are not using SharePoint, skip this section.

Viewing Excel workbooks or Power View reports that contain tabular data requires that the account used to run Excel Services or Reporting Services has administrator permissions on the Analysis Services instance. Administrative permissions are required so that these services are trusted by the Analysis Services instance.

Grant administrative access on the server

1. In Central Administration, open the Configure service accounts page.
2. Select the service application pool used by Excel Services. It might **Service Application Pool - SharePoint Web Services System** or a custom application pool. The managed account used by Excel Services will appear on the page.

For SharePoint farms that include Reporting Services in SharePoint mode, get the account information for the Reporting Services service application as well.

In the following steps, you will add these accounts to the Server role on the Analysis Services instance.

3. In SQL Server Management Studio, connect to the instance of Analysis Services, right-click the server instance, and select **Properties**. In Object Explorer, right-click **Roles** and select **New Role**.

4. In the Analysis Services Properties page, click **Security**.
5. Click **Add**, and then enter the account used by Excel Services, followed by the account used by Reporting Services.

Connecting from Excel or SharePoint

Client libraries that provide access to Analysis Services databases can be used to connect to model databases that run on a tabular mode server. Libraries include the Analysis Services OLE DB provider, ADOMD.NET, and AMO.

Excel uses the OLE DB provider. If you have either MSOLAP.4 from SQL Server 2008 R2 (file name msolap100.dll, version 10.50.1600.1), or MSOLAP.5 (filename msolap110.dll) that is installed with the SQL Server 2012 (11.x) version of Power Pivot for Excel, you have a version that will connect to tabular databases.

Choose from the following approaches to connect to model databases from Excel:

- Create a data connection from within Excel, using the instructions provided in the next section.
- Create a BI semantic model connection (.bism) file in SharePoint that provides redirection to a database running on an Analysis Services tabular mode server. A BI semantic model connection file provides a right-click command that launches Excel using the model database that you specified in the connection. It will also launch Power View if Reporting Services is installed. For more information about creating and using BI semantic model connection files, see [Create a BI Semantic Model Connection to a Tabular Model Database](#).
- Create a Reporting Services shared data source that references a tabular database as the data source. You can create the shared data source in SharePoint and use it to launch Power View.

Connect from Excel

1. In Excel, on the **Data** tab, in **Get External Data**, click **From Other Sources**.
2. Select **From Analysis Services**.
3. In **Server Name**, specify the Analysis Services instance that hosts the database. The server name is often the name of the computer that runs the server software. If the server was installed as a named instance, you must specify the name in this format: <servername>\<instancename>.

The server instance must be configured for standalone tabular deployment and the server instance must have an inbound rule that allows access to it. For more information, see [Determine the Server Mode of an Analysis Services Instance](#) and [Configure the Windows Firewall to Allow Analysis Services Access](#).

4. For log on credentials, choose **Use Windows Authentication** if you have read permissions to the database. Otherwise, choose **Use the Following User Name and Password**, and enter the username and password of a Windows account that has database permissions. Click **Next**.
5. Select the database. A valid selection will show a single **Model** cube for the database. Click **Next** and then click **Finish**.

After the connection is established, you can use the data to create a PivotTable or PivotChart. For more information, see [Analyze in Excel](#).

Connect from SharePoint

If you are using Power Pivot for SharePoint, you can create a BI semantic model connection file in SharePoint that provides redirection to a database running on an Analysis Services tabular mode server. A BI semantic model connection provides an HTTP endpoint to a database. It also simplifies tabular model access for knowledge workers who routinely use documents on a SharePoint site. Knowledge workers only need to know the location of the BI semantic model connection file or its URL to access tabular model databases. Details about server location or database name are encapsulated in the BI semantic model connection. For more information about creating and

using BI semantic model connection files, see [Power Pivot BI Semantic Model Connection \(.bism\)](#) and [Create a BI Semantic Model Connection to a Tabular Model Database](#).

Troubleshooting connection problems

This section provides cause and resolution steps for problems that occur while connecting to a tabular model database.

The Data Connection Wizard cannot obtain a list of databases from the specified data source.

When importing data, this Microsoft Excel error occurs when you try to use the Wizard to Connect to a tabular model database on a remote Analysis Services server, and you do not have sufficient permissions. To resolve this error, you must have user access rights on the database. Refer to the instructions provided earlier in this topic for granting user access to data.

An error occurred during an attempt to establish a connection to the external data source. The following connections failed to refresh: <model name> Sandbox

On SharePoint, this Microsoft Excel error occurs when you attempt data interaction, such as filtering data, in a PivotTable that uses model data. The error occurs because you do not have sufficient permissions on the remote Analysis Services server. To resolve this error, you must have user access rights on the database. Refer to the instructions provided earlier in this topic for granting user access to data.

An error occurred while attempting to perform this operation. Reload the workbook, and then try to perform this operation again.

On SharePoint, this Microsoft Excel error occurs when you attempt data interaction, such as filtering data, in a PivotTable that uses model data. The error occurs because Excel Services is not trusted by the Analysis Services instance on which the model data is deployed. To resolve this error, grant Excel Services administrative permission on the Analysis Services instance. Refer to the instructions provided earlier in this topic for granting administrator permissions. If the error persists, recycle the Excel Services application pool.

An error occurred during an attempt to establish a connection to the external data source used in the workbook

On SharePoint, this Microsoft Excel error occurs when you attempt data interaction, such as filtering data, in a PivotTable that uses model data. The error occurs because the user does not have sufficient SharePoint permissions on the workbook. The user must have **Read** permissions or above. **View-Only** permissions are not sufficient for data access.

Multidimensional models

8/27/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

An Analysis Services multidimensional solution uses cube structures for analyzing business data across multiple dimensions. Multidimensional mode is the default server mode of Analysis Services. It includes a query and calculation engine for OLAP data, with MOLAP, ROLAP, and HOLAP storage modes to balance performance with scalable data requirements. The Analysis Services OLAP engine is an industry-leading OLAP server that works well with a broad range of BI tools. Most Analysis Services deployments are installed as classic OLAP servers.

Benefits of Using Multidimensional Solutions

The primary reason for building an Analysis Services multidimensional model is to achieve fast query performance against business data. A multidimensional model is composed of cubes and dimensions that can be annotated and extended to support complex query constructions. BI developers create cubes to support fast response times, and to provide a single data source for business reporting. Given the growing importance of business intelligence across all levels of an organization, having a single source of analytical data ensures that discrepancies are kept to a minimum, if not eliminated entirely.

Another important benefit to using Analysis Services multidimensional databases is integration with commonly used BI reporting tools such as Excel, Reporting Services, and PerformancePoint, as well as custom applications and third-party solutions.

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Microsoft SQL Server provides two different environments for building, deploying, and managing Analysis Services solutions: Visual Studio with Analysis Services projects and SQL Server Management Studio. Both of these environments implement a project system. For more information about Visual Studio projects, see [Projects as Containers](#) in the MSDN Library.

- Visual Studio with Analysis Services projects is a development environment, based on Microsoft Visual Studio 2010, used for creating and modifying business intelligence solutions. With Visual Studio with Analysis Services projects, you create Analysis Services projects that contain definitions of Analysis Services objects (cubes, dimensions, and so on), which are stored in XML files that contain Analysis Services Scripting Language (ASSL) elements. These projects are contained in solutions that can also contain projects from other SQL Server components, including SQL Server Integration Services and SQL Server Reporting Services. In Visual Studio with Analysis Services projects, you can develop Analysis Services projects as part of a solution that is independent of any particular Analysis Services instance. You can deploy the objects to an instance on a test server for testing during development, and then use the same Analysis Services project to deploy your objects to instances on one or more staging or production servers. The projects and items in a solution that includes Analysis Services, Integration Services, and Reporting Services can be integrated with source code control, such as Microsoft Visual SourceSafe. For more information about creating an Analysis Services project in Visual Studio with Analysis Services projects using Analysis Services, see [Create an Analysis Services Project \(SSDT\)](#). You can also use Visual Studio with Analysis Services projects to connect directly to an existing Analysis Services instance to create and modify Analysis Services objects, without working with a project and without storing object definitions in XML files. For more information, see [Multidimensional Model Databases](#), and [Connect in Online Mode to an Analysis Services Database](#).
- SQL Server Management Studio is a management and administration environment, used primarily to administer instances of Analysis Services, SQL Server, Integration Services, and Reporting Services. With SQL Server Management Studio, you can manage Analysis Services objects (perform back-ups, processing, and so on), and you can also create new objects directly on an existing Analysis Services instance by using XMLA scripts. SQL Server Management Studio provides an Analysis Server Scripts project in which you can develop and save scripts written in Multidimensional Expressions (MDX), Data Mining Extensions (DMX), and XML for Analysis (XMLA). Usually, Analysis Server Scripts projects are used for performing management tasks or re-creating objects, such as databases and cubes, on Analysis Services instances. Such projects can be saved as part of a solution and integrated with source code control. For more information about creating an Analysis Server Scripts project in SQL Server Management Studio using Analysis Services, see [Analysis Services Scripts Project in SQL Server Management Studio](#).

Introducing Solutions, Projects, and Items

Both Visual Studio with Analysis Services projects and SQL Server Management Studio provide projects, which are organized into solutions. A solution can contain multiple projects, and a project typically contains multiple items. A new solution is automatically generated when you create a project, and you can add additional projects as needed to an existing solution. The objects that a project contains depend on the type of the project. The items in each project container are saved as files in project folders in the file system.

Visual Studio with Analysis Services projects contains the following projects under the Business Intelligence Projects project type.

| PROJECT | DESCRIPTION |
|--|--|
| Analysis Services Project | Contains the object definitions for a single Analysis Services database. For more information about how to create an Analysis Services project, see Create an Analysis Services Project (SSDT) . |
| Import Analysis Services 2008 Database | Provides a wizard that you can use to create a new Analysis Services project by importing object definitions from an existing Analysis Services database. |
| Integration Services Project | Contains the object definitions for a set of Integration Services packages. For more information, see SQL Server Integration Services . |
| Report Project Wizard | Provides a wizard that guides you through the process of creating a Report project using Reporting Services. For more information, see Reporting Services (SSRS) . |
| Report Model Project | Contains the object definitions for a Reporting Services report model. For more information, see Reporting Services (SSRS) . |
| Report Server Project | Contains the object definitions for one or more Reporting Services reports. For more information, see Reporting Services (SSRS) . |

SQL Server Management Studio also contains several project types that focus on various queries or scripts, as shown in the following table.

| PROJECT | DESCRIPTION |
|----------------------------|---|
| Analysis Services Scripts | Contains DMX, MDX, and XMLA scripts for Analysis Services, as well as connections to Analysis Services instances against which these scripts can be executed. For more information, see Analysis Services Scripts Project in SQL Server Management Studio . |
| SQL Server Compact Scripts | Contains SQL scripts for SQL Server Compact, as well as connections to SQL Server Compact instances against which these scripts can be executed. |
| SQL Server Scripts | Contains Transact-SQL and XQuery scripts for a SQL Server Database Engine instance, as well as connections to SQL Server Database Engine instances against which these scripts can be executed. For more information, see SQL Server Database Engine . |

For more information about solutions and projects, see "Managing Solutions, Projects, and Files," either in the Microsoft Visual Studio .NET documentation or in the MSDN Library.

Choosing Between SQL Server Management Studio and SQL Server Data Tools

SQL Server Management Studio is designed for administering and configuring existing objects in SQL Server

Database Engine, Analysis Services, Integration Services, and Reporting Services. Visual Studio with Analysis Services projects is designed for developing business intelligence solutions that include functionality from Analysis Services, Integration Services, and Reporting Services.

The following are some of the differences between SQL Server Management Studio from Visual Studio with Analysis Services projects.

- SQL Server Management Studio provides an integrated environment for connecting to instances of Analysis Services, SQL Server, and Reporting Services to configure, manage, and administer objects within an instance of Analysis Services. Through the use of scripts, you can also use SQL Server Management Studio to create or modify Analysis Services objects themselves, but SQL Server Management Studio does not provide a graphical interface for object design and definition.
- Visual Studio with Analysis Services projects provides an integrated development environment for developing business intelligence solutions. You can use Visual Studio with Analysis Services projects in project mode, which uses XML-based definitions of Analysis Services, Integration Services, and Reporting Services objects contained in projects and solutions. Using Visual Studio with Analysis Services projects in project mode means that changes to Analysis Services objects in Visual Studio with Analysis Services projects are made to these XML-based object definitions and not applied directly to an object on an Analysis Services instance until the solution is deployed. You can also use Visual Studio with Analysis Services projects in online mode, which means connecting directly to an Analysis Services instance and working with objects in an existing database.

Visual Studio with Analysis Services projects enhances the development of business intelligence applications because you can work on Analysis Services projects in a source-controlled, multi-user environment without requiring an active connection to an Analysis Services instance. SQL Server Management Studio provides direct access to existing objects for querying and testing, and can be used to more quickly implement previously scripted Analysis Services databases. However, once a project has been deployed into the production environment, care must be taken when working with an Analysis Services database and its objects with SQL Server Management Studio and Visual Studio with Analysis Services projects. This is to avoid overwriting changes made to objects directly in an existing database, and changes made to the Analysis Services project that originally generated the deployed solution. For more information, see [Working with Analysis Services Projects and Databases During the Development Phase](#), and [Working with Analysis Services Projects and Databases in a Production Environment](#).

[Multidimensional Model Databases](#)

Create an Analysis Services Project (SSDT)

7/16/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can define an Analysis Services project in Visual Studio with Analysis Services projects either by using the Analysis Services Project template or by using the Import Analysis Services Database Wizard to read the contents of an Analysis Services database. If no solution is currently loaded in Visual Studio with Analysis Services projects, creating a new Analysis Services project automatically creates a new solution. Otherwise, the new Analysis Services project will be added to the existing solution. Best practices for solution development call for creating separate projects for different types of application data, using a single solution if the projects are related. For example, you might have a single solution that contains separate projects for Integration Services packages, Analysis Services databases, and Reporting Services reports that are all used by the same business application.

An Analysis Services project contains objects used in a single Analysis Services database. The deployment properties of the project specify the server and database name by which the project metadata will be deployed as instantiated objects.

This topic contains the following sections:

[Create a New Project Using the Analysis Services Project Template](#)

[Create a New Project Using an Existing Analysis Services Database](#)

[Add an Analysis Services Project to an Existing Solution](#)

[Build and Deploy the Solution](#)

[Analysis Services Project Folders](#)

[Analysis Services File Types](#)

[Analysis Services Item Templates](#)

Create a New Project Using the Analysis Services Project Template

Use these instructions to create an empty project in which you define Analysis Services objects that you can then deploy as a new Analysis Services database.

1. In Visual Studio with Analysis Services projects, click **File**, point to **New**, and click **Project**. In the **New Project** dialog box, in the **Project types** pane, select **Business Intelligence Projects**.
2. In the **New Project** dialog box, in the **Visual Studio installed templates** category, select **Analysis Services Project**.
3. In the **Name** text box, type the name of the project. The name you enter will be used as the default database name.
4. In the **Location** drop-down list, type or select the folder in which to store the files for the project, or click **Browse** to select a folder.
5. To add the new project to the existing solution, in the **Solution** drop-down list, select **Add to Solution**.

-or-

To create a new solution, in the **Solution** drop-down list, select **Create new Solution**. To create a new folder for the new solution, select **Create directory for solution**. In **Solution Name**, type the name of the new solution.

6. Click **OK**.

Create a New Project Using an Existing Analysis Services Database

Use the Import Analysis Services Database Wizard to create a project based on the objects in the existing Analysis Services database. When you define an Analysis Services project based on an existing Analysis Services database, the metadata for that database will open in an Analysis Services project in Visual Studio with Analysis Services projects. These objects can then be modified within the project without affecting the original objects, and then be deployed to the same Analysis Services database if the deployment properties specify that database, or to a newly created Analysis Services database for comparison testing. Until the changes are deployed, no changes made will affect the existing Analysis Services database.

You can also use the Import Analysis Services Database template to create a project from a production database to which changes have been made directly since the original Analysis Services project was deployed.

Before you process or deploy the project, you might need to change the data provider that is specified in the data sources. If the SQL Server software you are using is newer than the software used to create the database, the data provider specified in your project might not be installed on your computer. During processing, the service account will be used to retrieve the data in your Analysis Services database. If the database is on a remote server, check whether the local service has process and read permissions on that server.

1. In Visual Studio with Analysis Services projects, click **File**, point to **New**, and click **Project**. In the **New Project** dialog box, in the **Project types** pane, select **Business Intelligence Projects**.
2. In the **New Project** dialog box, in the **Visual Studio installed templates** category, select **Import Analysis Services Database**.
3. Enter property information for the project and solution, including name and location for the files. Click **OK**.
4. On the Welcome to the **Import Analysis Services Database Wizard** page, click **Next**.

5. On the **Source Database** page, specify the server and the database from which the wizard will extract the contents and create the Analysis Services project, and then click **Next**.

Supported databases include those created in the following versions of Analysis Services: SQL Server 2005 (9.x), SQL Server 2008, SQL Server 2008 R2, and SQL Server 2012 (11.x).

You can either type the database name or query the server to view the existing databases on the server. If the database is on a remote server or production server, you might need to request permission to read the database. Firewall configuration settings can further restrict access to a database. If you get an error while attempting to connect to the database, check permissions and firewall settings first.

6. When the wizard finishes extracting the contents of the Analysis Services database, click **Finish** on the **Completing the Wizard** page.
7. Open the Solution Explorer window to view the contents of the project.

Add an Analysis Services Project to an Existing Solution

If you already have a solution that contains all the source files of a business application, you can add a new Analysis Services project to that solution.

Adding an existing project to a solution associates, but does not copy, the project with the solution. If the Analysis Services project was created in a different solution, the project files remain with the original solution for which it

was created. This means that any changes you make to the project through either solution will operate on the same set of source files. If this behavior is not what you intend, you should copy or move the project files to the new solution folder first, and then add the project to the solution.

1. Open the solution in Visual Studio with Analysis Services projects. In Solution Explorer, right-click the solution, point to **Add**, and then click **Existing Project** to select the project you want to add.
2. Select a .dwproj file to add to the solution.

Build and Deploy the Solution

By default, Visual Studio with Analysis Services projects deploys a project to the default instance of Analysis Services on the local computer. You can change this deployment destination by using the **Property Pages** dialog box for the Analysis Services project to change the **Server** configuration property.

NOTE

By default, Visual Studio with Analysis Services projects processes only objects changed by the deployment script and dependent objects when deploying a solution. You can change this functionality by using the **Property Pages** dialog box for the Analysis Services project to change the Processing Option configuration property.

Build and deploy the solution to an instance of Analysis Services for testing. Building a solution validates the object definitions and dependencies in the project and generates a deployment script. Deploying a solution uses the Analysis Services deployment engine to send the deployment script to a specified instance.

After you deploy the project, review and test the deployed database. You can then modify object definitions, build, and deploy again until the project is complete.

After the project is complete, you can use the Deployment Wizard to deploy the deployment script, generated when you build the solution, to destination instances for final testing, staging, and deployment.

Analysis Services Project Folders

An Analysis Services project contains the following folders, which are used to organize items included in the project.

| FOLDER | DESCRIPTION |
|-------------------|--|
| Data Sources | Contains data sources for an Analysis Services project. You create these objects with the Data Source Wizard and edit them in Data Source Designer. |
| Data Source Views | Contains data source views for an Analysis Services project. You create these objects with the Data Source View Wizard and edit them in Data Source View Designer. |
| Cubes | Contains cubes for an Analysis Services project. You create these objects with the Cube Wizard and edit them in Cube Designer. |
| Dimensions | Contains dimensions for an Analysis Services project. You create these objects with the Dimension Wizard or the Cube Wizard and edit them in Dimension Designer. |

| FOLDER | DESCRIPTION |
|-------------------|--|
| Mining Structures | Contains mining structures for an Analysis Services project. You create these objects with the Mining Model Wizard and edit them in Mining Model Designer. |
| Roles | Contains database roles for an Analysis Services project. You create and manage roles in Role Designer. |
| Assemblies | Contains references to COM libraries and Microsoft .NET Framework assemblies for an Analysis Services project. You create references with the Add Reference dialog box. |
| Miscellaneous | Contains any type of file except for Analysis Services file types. Use this folder to add any miscellaneous files, such as text files that contain notes on the project. |

Analysis Services File Types

A Visual Studio with Analysis Services projects solution can contain several file types, depending on what projects you included in the solution and what items you included in each project for that solution. Typically, the files for each project in a Visual Studio with Analysis Services projects solution are stored in the solution folder, in a separate folder for each project.

NOTE

Copying a file for an object to a project folder does not add the object to the project. You must use the **Add** command from the project's context menu in Visual Studio with Analysis Services projects to add an existing object definition to a project.

The project folder for an Analysis Services project can contain the file types listed in the following table.

| FILE TYPE | DESCRIPTION |
|--|---|
| Analysis Services project definition file (.dwproj) | Contains metadata about the items, configurations, and assembly references defined and included in the Analysis Services project. |
| Analysis Services project user settings (.dwproj.user) | Contains configuration information for the Analysis Services project, for a specific user. |
| Data source file (.ds) | Contains Analysis Services Scripting Language (ASSL) elements that define metadata for a data source. |
| Data source view file (.dsv) | Contains ASSL elements that define metadata for a data source view. |
| Cube file (.cube) | Contains ASSL elements that define metadata for a cube, including measure groups, measures, and cube dimensions. |
| Partition file (.partitions) | Contains ASSL elements that define metadata for the partitions of a specified cube. |

| FILE TYPE | DESCRIPTION |
|------------------------------|--|
| Dimension file (.dim) | Contains ASSL elements that define metadata for a database dimension. |
| Mining structure file (.dmm) | Contains ASSL elements that define metadata for a mining structure and associated mining models. |
| Database file (.database) | Contains ASSL elements that define metadata for a database, including account types, translations, and database permissions. |
| Database role file (.role) | Contains ASSL elements that define metadata for a database role, including role members. |

Analysis Services Item Templates

If you use the **Add New Item** dialog box to add new items to an Analysis Services project, you have the option of using an item template, a predefined script or statement which demonstrates how to perform a specified action.

The item templates, listed in the following table, are available in the Analysis Services Project Items category in the **Add New Item** dialog box.

| CATEGORY | ITEM TEMPLATE | DESCRIPTION |
|---------------------------------|------------------|---|
| Analysis Services Project Items | Cube | Starts the Cube Wizard to add a new cube to the Analysis Services project. |
| | Data Source | Starts the Data Source Wizard to add a new data source to the Analysis Services project. |
| | Data Source View | Starts the Data Source View Wizard to add a new data source view to the Analysis Services project. |
| | Database Role | Adds a new database role to the Analysis Services project, and then displays Role Designer for the new database role. |
| | Dimension | Starts the Dimension Wizard to add a new database dimension to the Analysis Services project. |
| | Mining Structure | Starts the Data Mining Wizard to add a new mining structure and associated mining model to the Analysis Services project. |

[Deploy Analysis Services Projects \(SSDT\)](#)

Configure Analysis Services Project Properties (SSDT)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Visual Studio with Analysis Services projects, an Analysis Services project is defined with certain default properties that affect building and deploying the Analysis Services project.

To change project properties, right-click the Analysis Services project object and then click **Properties**. Alternatively, you can click **Properties** on the Project menu.

Property Description

The following table describes each project property, lists its default value, and provides information about changing its value.

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|-----------------------------------|--|---|
| Build / Deployment Server Edition | The SQL Server edition used to develop the project | Specifies the edition of the server to which projects will finally be deployed. When working with multiple developers on a project, developers need to understand the server edition to know which features to incorporate into the Analysis Services project. |
| Build / Deployment Server Version | The version used to develop the projects | Specifies the version of the server to which projects will finally be deployed. |
| Build / Outputs | /bin | The relative path for the output of the project build process |
| Build / Remove Passwords | True | Specifies whether known passwords will be removed from connection strings that are written to the output directory during the build process. Passwords are removed to increase security. If passwords are removed, they will need to be provided when the deployed project is processed in order for Analysis Services to access the source data. |
| Debugging / Start Object | <Currently Active Object> | Determines that object that will be started when you start debugging. |

| PROPERTY | DEFAULT SETTING | DESCRIPTION |
|---------------------------------------|---------------------|--|
| Deployment / Deployment Mode | Deploy Changes Only | By default, only changes to project objects are deployed (provided that no other changes were made to the objects directly outside of the project). You can also choose to have all project objects deployed during each deployment. For best performance, use Deploy Changes Only. |
| Deployment / Processing Option | Default | By default, Analysis Services will determine the type of processing required when changes to objects are deployed. This generally results in the fastest deployment time. However, you can also choose to have either full processing or no processing performed with each deployment. |
| Deployment / Transactional Deployment | False | By default, the deployment of changed or all objects is not transactional with the processing of those deployed objects. Deployment can succeed and persist even though processing fails. You can change this default to incorporate deployment and processing in a single transaction. |
| Deployment / Target Server | localhost | By default, database objects within the Analysis Services project will be deployed to the default instance of Analysis Services on the local computer on which Visual Studio with Analysis Services projects is being used. Change this default to specify a named instance on the local computer or any instance on any remote computer on which you have permission to create Analysis Services objects. |
| Deployment / Database | <project name> | By default, the name of the Analysis Services database in which the Analysis Services project objects will be instantiated upon deployment is the name of the Analysis Services project at the time it was defined. Change this property to change the name of database on the Analysis Services instance specified by the Server property. |

Property Configurations

Properties are defined on a per configuration basis. Project configurations enable developers to work with an Analysis Services project with different build, debugging, and deployment settings without editing the underlying XML project files directly.

A project is initially created with a single configuration, called Development. You can create additional configurations and switch between configurations using the Configuration Manager.

Until additional configurations are created, all developers use this common configuration. However, during the various phases of project development - such as during the initial development and testing of a project - different developers will may use different data sources and deploy the project to different servers for different purposes. Configurations enable you to retain these different settings in different configuration files.

[Deploy Analysis Services Projects \(SSDT\)](#)

Build Analysis Services Projects

11/8/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Visual Studio with Analysis Services projects, you build an Analysis Services project much like you build any programming project in Visual Studio. When you build the project, a set of XML files are created in the output directory. These XML files use Analysis Services Scripting Language (ASSL), which is the XML dialect the client applications including SQL Server Management Studio and Visual Studio with Analysis Services projects use to communicate with an Analysis Services instance to create or modify Analysis Services objects. These XML files are used to deploy Analysis Services object definitions in an Analysis Services project to a specified Analysis Services instance.

Building a Project

When you build an Analysis Services project, Visual Studio with Analysis Services projects will build a complete set of XML files in the output folder containing all of the necessary ASSL commands needed to build all of the Analysis Services database objects in the project. If the project was previously built and incremental deployment specified for the active configuration, Visual Studio with Analysis Services projects will also build an XML file containing the ASSL commands to perform an incremental update to the deployed objects. This XML file is written to the ..\obj\<active configuration> folder for the project. Incremental builds can save time when deploying and processing a very large project or database.

NOTE

You can use the Rebuild All command to ignore the incremental deployment setting.

Building an Analysis Services project validates the object definitions in the project. The validation includes any referenced assemblies. Build errors appear in the Task List window, along with the Analysis Management Objects (AMO) error text. You can click an error to open the designer that is required to fix the error.

Successful validation does not guarantee that objects can be created on the destination server during deployment or processed successfully after deployment. The following issues can prevent successful deployment or processing after deployment:

- Security checks for the server are not performed, so locks can prevent deployment.
- Physical locations are not validated on the server.
- Details of data source views are not checked against the actual data source on the destination server.

If validation is successful, Visual Studio with Analysis Services projects generates the XML files. After the build, the output folder will contain the files described in the following table.

| FILES (IN BIN FOLDER) | DESCRIPTION |
|-------------------------------|--|
| <i>Projectname.asdatabase</i> | Contains the ASSL elements that define metadata for the objects in the Analysis Services project in a deployment script file. This file is used by the deployment engine to deploy the objects to an Analysis Services database. |

| FILES (IN BIN FOLDER) | DESCRIPTION |
|--------------------------------------|--|
| <i>Projectname.configsettings</i> | Contains configuration settings used during deployment that you can modify directly or in the Analysis Services Deployment Wizard (for example, the connection string for the data sources). |
| <i>Projectname.deploymenttargets</i> | Contains the destination settings used during deployment that you can modify directly or in the Analysis Services Deployment Wizard (for example, the server and database names) |
| <i>Projectname.deploymentoptions</i> | Contain various option settings used during deployment that you can modify directly or in the Analysis Services Deployment Wizard (for example, storage locations) |
| <i>Assemblyname/*dllname.*dll</i> | Separate folders for each referenced assembly; each folder contains the DLL for the assembly, any referenced assembly, and any associated .pdb files for output debug information. |

| FILES (IN OBJ FOLDER) | DESCRIPTION |
|------------------------------------|--|
| <Configuration Name>\LastBuilt.xml | Contains the time stamp and hash code that identifies the last time the Analysis Services project was built. |

These XML files do not contain <Create> and <Alter> tags, which are constructed during deployment.

Referenced assemblies (excluding standard system and Analysis Services assemblies) are also copied to the output directory. When references are to other projects in a solution, those projects are built first, using the appropriate project configuration and build dependencies established by the project references, and then are copied to the project output folder.

[Analysis Services Scripting Language \(ASSL for XMLA\)](#)

[Deploy Analysis Services Projects \(SSDT\)](#)

Deploy Analysis Services Projects (SSDT)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

During development of an Analysis Services project in Visual Studio with Analysis Services projects, you frequently deploy the project to a development server in order to create the Analysis Services database defined by the project. This is required to test the project; for example, to browse cells in the cube, browse dimension members, or verify key performance indicators (KPIs) formulas.

Deploying a Project

You can deploy a project independently, or you can deploy all of the projects within the solution. When you deploy a project, several things happen in sequence. First, the project is built. This step creates the output files that define the Analysis Services database and its constituent objects. Next, the destination server is validated. Finally, the destination database and its objects are created on the destination server. During deployment, the deployment engine totally replaces any pre-existing database with the contents of the project unless those objects were created by the project during a previous deployment.

After an initial deployment, an IncrementalSnapshot.xml file is generated in the <Project Name>\obj folder. This file is used to determine if the database or its objects on the destination server have changed outside of the project. If so, you will be prompted to overwrite all objects in the destination database. If all changes were made within the project and the project is configured for incremental deployment, only the changes will be deployed to the destination server.

The project configuration and its associated settings determine the deployment properties that will be used to deploy the project. For a shared project, each developer can use their own configuration with their own project configuration options. For example, each developer can specify a different test server to work in isolation from other developers.

Create and Run an MDX Script in SQL Server Data Tools

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

To create and run an MDX Script in Analysis Services, you need to be in Visual Studio with Analysis Services projects with a cube already created and ready for editing.

To create a Multidimensional Expressions (MDX) script

1. Open the cube for which you want to create an MDX script, and under **View**, click **Calculations**.
2. If you are not in **Script View** mode, click the **Script View** icon.
3. In the script window, under the CALCULATE command, type an MDX expression. Click the **Check Syntax** icon and verify that the expression is syntactically correct.
4. To run the MDX script, deploy and process the cube with the new MDX script changes.

View the XML for an Analysis Services Project (SSDT)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you are working with an Analysis Services database in project mode, Visual Studio with Analysis Services projects creates an XML definition for each object within the project folder. You can view the contents of the XML file for each object within Visual Studio with Analysis Services projects. You can also edit the XML file directly; however, this is not recommended in most circumstances as you may make changes that make the XML unreadable by Visual Studio with Analysis Services projects.

NOTE

You cannot view the xml code for an entire project, but rather you view the code for each object because a separate file exists for each object. The only way to view the code for an entire project is to build the project and view the ASSL code in the <project name>.asdatabase file.

To view the XML code for an object

1. Open the Analysis Services project in Visual Studio with Analysis Services projects.
2. Right-click the object in Solution Explorer and then click **View Code**.

The XML code for the object appears in Visual Studio with Analysis Services projects.

[Build Analysis Services Projects \(SSDT\)](#)

Connect in Online Mode to an Analysis Services Database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can connect directly to an existing Microsoft SQL Server Analysis Services database and directly modify objects within that database. When you connect directly to an Analysis Services database, changes to objects occur immediately and no Analysis Services project is created within Visual Studio with Analysis Services projects.

To Connect Directly to an Analysis Services Database by using SQL Server Data Tools

1. Open Visual Studio with Analysis Services projects.
2. On the **File** menu, point to **Open** and then click **Analysis Services Database**.
3. Select **Connect to existing database**.
4. Specify the server name and the database name.

You can either type the database name or query the server to view the existing databases on the server.

5. Click **OK**.

You can now directly edit any objects within the Analysis Services database.

Work with Analysis Services Projects and Databases in Development

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can develop an Analysis Services database by using Visual Studio with Analysis Services projects in either project mode or online mode.

Single Developer

When only a single developer is developing the entire Analysis Services database and all of its constituent objects, the developer can use Visual Studio with Analysis Services projects in either project mode or online mode at any time during the lifecycle of the business intelligence solution. In the case of a single developer, the choice of modes is not particularly critical. The maintenance of an offline project file integrated with a source control system has many benefits, such as archiving and rollback. However, with a single developer you will not have the problem of communicating changes with another developer.

Multiple Developers

When multiple developers are working on a business intelligence solution, problems will arise if the developers do not work in project mode with source control under most, if not all circumstances. Source control ensures that two developers are not making changes to the same object at the same time.

For example, suppose a developer is working in project mode and making changes to selected objects. While the developer is making these changes, suppose that another developer makes a change to the deployed database in online mode. A problem will arise when the first developer attempts to deploy his or her modified Analysis Services project. Namely, Visual Studio with Analysis Services projects will detect that objects have changed within the deployed database and prompt the developer to overwrite the entire database, overwriting the changes of the second developer. Since Visual Studio with Analysis Services projects has no means of resolving the changes between the Analysis Services database instance and the objects in the project about to be overwritten, the only real choice the first developer has is to discard all of his or her changes and starting anew from a new project based on the current version of the Analysis Services database.

Work with Analysis Services Projects and Databases in Production

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

After you have developed and deployed your Analysis Services database from your Analysis Services project to an Analysis Services instance, you must decide how you wish to make changes to objects in the deployed database. Certain changes, such as changes related to security roles, partitioning, and storage settings, can be made using either SQL Server Management Studio or Visual Studio with Analysis Services projects. Other changes can only be made using Visual Studio with Analysis Services projects, either in project mode or in online mode (such as adding attributes or user-defined hierarchies).

As soon as you make a change to a deployed Analysis Services database using either SQL Server Management Studio or Visual Studio with Analysis Services projects in online mode, the Analysis Services project that was used for deployment becomes out of date. If a developer makes any changes within the Analysis Services project and attempts to deploy the modified project, the developer will be prompted to overwrite the entire database. If the developer overwrites the entire database, it must also be processed. This issue becomes compounded if the changes made directly to the deployed database by the production staff were not communicated to the development team because they will not understand why their changes no longer appear in the Analysis Services database.

There are several ways in which you can use SQL Server Analysis Services tools to avoid the problems inherent in this situation.

- Method 1: Whenever a change is made to a production version of an Analysis Services database, use Visual Studio with Analysis Services projects to create a new Analysis Services project based on the modified version of the Analysis Services database. This new Analysis Services project can be checked into the source control system as the master copy of the project. This method will work regardless of whether the change was made to the Analysis Services database using SQL Server Management Studio or Visual Studio with Analysis Services projects in online mode.
- Method 2: Only make changes to the production version of an Analysis Services database using SQL Server Management Studio or Visual Studio with Analysis Services projects in project mode. With this method, you can use options available to you in the Analysis Services Deployment Wizard to preserve changes made by SQL Server Management Studio, such as security roles and storage settings. This ensures that the design-related settings are kept in the project file (storage settings and security roles can be ignored) and the online server is used for storage settings and security roles.
- Method 3: Only make changes to the production version of an Analysis Services database using SQL Server Management Studio or Visual Studio with Analysis Services projects in online mode. Since both tools are only working with the same online server, there are no possibilities of getting different versions out of sync.

Data Sources in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

All data that you import or load into a multidimensional model originates from an external data source. Typically, source data is from a data warehouse designed for reporting purposes, but it could come from any relational database that is accessed directly or indirectly through an intermediary, such as an SSIS package.

A **data source** object in Analysis Services specifies a direct connection to an external data source. In addition to physical location, a data source object specifies the connection string, data provider, credentials, and other properties that control connection behavior.

Information provided by the data source object is used during the following operations:

- Get schema information and other metadata used to generate data source views into a model.
- Query or load data into a model during processing.
- Run queries against multidimensional or data mining models that use ROLAP storage mode.
- Read or write to remote partitions.
- Connect to linked objects, as well as synchronize from target to source.
- Perform write back operations that update fact table data stored in a relational database.

When building a multidimensional model from the bottom up, you start by creating the data source object, and then use it to generate the next object, a **data source view**. A data source view is the data abstraction layer in the model. It is typically created after the data source object, using the schema of the source database as the basis. However, you can choose other ways to build a model, including starting with cubes and dimensions, and generating the schema that best supports your design.

Regardless of how you build it, each model requires at least one data source object that specifies a connection to source data. You can create multiple data source objects in a single model to use data from different sources or vary connection properties for specific objects.

Data source objects can be managed independently of other objects in your model. After you create a data source, you can change its properties later, and then preprocess the model to ensure the data is retrieved correctly.

Supported Data Sources (SSAS - Multidimensional)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This topic describes the types of data sources that you can use in a multidimensional model.

Supported Data Sources

You can retrieve data from the data sources in the following table. When you install Visual Studio with Analysis Services projects, setup does not install the providers that are listed for each data source. Some providers might already be installed with other applications on your computer; in other cases you will need to download and install the provider.

NOTE

Third party providers, such as the Oracle OLE DB Provider, may also be used to connect to third party databases, with support provided by those third parties.

| Source | Versions | File type | Providers* |
|------------------|-----------------------------------|----------------|-----------------------------------|
| Access databases | Microsoft Access 2010, 2013, 2016 | .accdb or .mdb | Microsoft Jet 4.0 OLE DB provider |

| | | | |
|--|--|------------------|---|
| SQL Server relational databases* | <p>Microsoft SQL Server 2008, 2008 R2, 2012, 2014, 2016, Azure SQL Database, Azure SQL Data Warehouse, Microsoft Analytics Platform System (APS)</p> <p>Note: For more information about SQL Database on Azure.com.</p> <p>Note: Analytics Platform System (APS) was formerly known as SQL Server Parallel Data Warehouse (PDW). Originally, connecting to PDW from Analysis Services required a special data provider. This provider was replaced in SQL Server 2012. Starting in SQL Server 2012, the SQL Server native client is used for connections to PDW/APS. For more information about APS, see the web site Microsoft Analytics Platform System.</p> | (not applicable) | <p>OLE DB Provider for SQL Server</p> <p>SQL Server Native Client OLE DB Provider</p> <p>SQL Server Native 11.0 Client OLE DB Provider</p> <p>.NET Framework Data Provider for SQL Client</p> |
| Oracle relational databases | Oracle 9i, 10g, 11g, 12g | (not applicable) | <p>Oracle OLE DB Provider</p> <p>.NET Framework Data Provider for Oracle Client</p> <p>.NET Framework Data Provider for SQL Server</p> <p>OraOLEDB</p> <p>MSDASQL</p> |
| Teradata relational databases | Teradata V2R6, V12 | (not applicable) | <p>TDOLEDB OLE DB provider</p> <p>.Net Data Provider for Teradata</p> |
| Informix relational databases | V11.10 | (not applicable) | Informix OLE DB provider |
| IBM DB2 relational databases | 8.1 | (not applicable) | DB2OLEDB |
| Sybase Adaptive Server Enterprise (ASE) relational databases | 15.0.2 | (not applicable) | Sybase OLE DB provider |
| Other relational databases | (not applicable) | (not applicable) | An OLE DB provider |

* ODBC data sources are not supported for multidimensional solutions. Although Analysis Services itself will handle the connection, the designers in Visual Studio with Analysis Services projects used for building solutions cannot connect to an ODBC data source, even when using the MSDASQL driver. If your business requirements include an ODBC data source, consider building a Tabular solution instead.

** Some features require a SQL Server relational database that runs on-premises. Specifically, writeback, and ROLAP storage require that the underlying data source is a SQL Server relational database.

Create a Data Source (SSAS Multidimensional)

7/16/2019 • 12 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In an Analysis Services multidimensional model, a data source object represents a connection to the data source from which you are processing (or importing) data. A multidimensional model must contain at least one data source object, but you can add more to combine data from several data warehouses. Use the instructions in this topic to create a data source object for your model. For more information about setting properties on this object, see [Set Data Source Properties \(SSAS Multidimensional\)](#).

This topic includes the following sections:

[Choose a Data Provider](#)

[Set Credentials and Impersonation Options](#)

[View or Edit Connection Properties](#)

[Create a Data Source Using the Data Source Wizard](#)

[Create a Data Source Using an Existing Connection](#)

[Add Multiple Data Sources to a Model](#)

Choose a Data Provider

You can connect using a managed Microsoft .NET Framework or native OLE DB provider. The recommended data provider for SQL Server data sources is SQL Server Native Client because it typically offers better performance.

For Oracle and other third-party data sources, check whether the third-party provides a native OLE DB provider and try that first. If you encounter errors, try one of the other .NET providers or native OLE DB providers listed in Connection Manager. Be sure that any data provider you use is installed on all computers used to develop and run the Analysis Services solution.

Set Credentials and Impersonation Options

A data source connection can sometimes use Windows authentication or an authentication service provided by the database management system, such as SQL Server authentication when connecting to SQL Azure databases. The account you specify must have a login on the remote database server and read permissions on the external database.

Windows Authentication

Connections that use Windows authentication are specified on the **Impersonation Information** tab of the Data Source Designer. Use this tab to choose the impersonation option that specifies the account under which Analysis Services runs when connecting to the external data source. Not all options can be used in all scenarios. For more information about these options and when to use them, see [Set Impersonation Options \(SSAS - Multidimensional\)](#).

Database Authentication

As an alternative to Windows authentication, you can specify a connection that uses an authentication service provided by the database management system. In some cases, using database authentication is required. Scenarios that call for using database authentication include using SQL Server authentication to connect to a

Windows Azure SQL Database, or accessing a relational data source that runs on a different operating system or in a non-trusted domain.

For a data source that uses database authentication, the username and password of a database login is specified on the connection string. Credentials are added to the connection string when you enter a user name and password in Connection Manager when setting up the data source connection in your Analysis Services model. Remember to specify a user identity that has read permissions to the data.

When retrieving data, the client library making the connection formulates a connection request that includes the credentials in the connection string. Windows authentication credential options in the Impersonation Information tab are not used in the connection, but can be used for other operations, such as accessing resources on the local computer. For more information, see [Set Impersonation Options \(SSAS - Multidimensional\)](#).

After you save the data source object in your model, the connection string and password are encrypted. For security purposes, all visible traces of the password are removed from the connection string when you subsequently view it in tools, script, or code.

NOTE

By default, Visual Studio with Analysis Services projects does not save passwords with the connection string. If the password is not saved, Analysis Services prompts you to enter the password when it is needed. If you choose to save the password, the password is stored in encrypted format in the data connection string. Analysis Services encrypts password information for data sources using the database encryption key of the database that contains the data source. With encrypted connection information, you must use SQL Server Configuration Manager to change the Analysis Services service account or password or the encrypted information cannot be recovered. For more information, see [SQL Server Configuration Manager](#).

Defining Impersonation Information for Data Mining Objects

Data mining queries may be executed in the context of the Analysis Services service account, but may also be executed in the context of the user submitting the query or in the context of a specified user. The context in which a query is executed may affect query results. For data mining **OPENQUERY** type operations, you may want the data mining query to execute in the context of the current user or in the context of a specified user (regardless of the user executing the query) rather than in the context of the service account. This enables the query to be executed with limited security credentials. If you want Analysis Services to impersonate the current user or to impersonate a specified user, select either the **Use a specific user name and password** or **Use the credentials of the current user** option.

Create a Data Source Using the Data Source Wizard

1. In Visual Studio with Analysis Services projects, open the Analysis Services project or connect to the Analysis Services database in which you want to define the data source.
2. In **Solution Explorer**, right-click the **Data Sources** folder, and then click **New Data Source** to start the **Data Source Wizard**.
3. On the **Select how to define the connection** page, choose **Create a data source based on an existing or new connection** and then click **New** to open **Connection Manager**.

New connections are created in Connection Manager. In Connection Manager, you select a provider and then specify the connection string properties used by that provider to connect to the underlying data. The exact information required depends upon the provider selected, but generally such information includes a server or service instance, information for logging on to the server or service instance, a database or file name, and other provider-specific settings. For the remainder of this procedure, we'll assume a SQL Server database connection.

4. Select the Microsoft .NET Framework or native OLE DB provider to use for the connection.

The default provider for a new connection is the Native OLE DB\SQL Server Native Client provider. This provider is used to connect to a SQL Server Database Engine instance using OLE DB. For connections to a SQL Server relational database, using Native OLE DB\SQL Server Native Client 11.0 is often faster than using alternative providers.

You can choose a different provider to access other data sources. For a list of the providers and relational databases supported by Analysis Services, see [Supported Data Sources \(SSAS - Multidimensional\)](#).

5. Enter the information requested by the selected provider to connect to the underlying data source. If the **Native OLE DB\SQL Server Native Client** provider is selected, enter the following information:

- a. **Server Name** is the network name of the Database Engine instance. It can be specified as the IP address, the NETBIOS name of the computer, or a fully qualified domain name. If the server is installed as a named instance, you must include the instance name (for example, <computername>\<instancename>).
- b. **Log on to the Server** specifies how the connection will be authentication. **Use Windows Authentication** uses Windows authentication. **Use SQL Server Authentication** specifies a database user login for a Windows Azure SQL databases or a SQL Server instance that supports mixed mode authentication.

IMPORTANT

Connection Manager includes a **Save my password** checkbox for connections that use SQL Server authentication. Although the checkbox is always visible, it is not always used.

Conditions under which Analysis Services does not use this checkbox include refreshing or processing the SQL Server relational data used in active Analysis Services database. Regardless of whether you clear or select **Save my password**, Analysis Services will always encrypt and save the password. The password is encrypted and stored in both .abf and data files. This behavior exists because Analysis Services does not support session-based password storage on the server.

This behavior only applies to databases that a) are persisted on an Analysis Services server instance, and b) use SQL Server authentication to refresh or process relational data. It does not apply to data source connections that you set up in Visual Studio with Analysis Services projects that are used only for the duration of a session. While there is no way to remove a password that is already stored, you can use different credentials, or Windows authentication, to overwrite the user information that is currently stored with the database.

- c. **Select or enter a database name** or **Attach a database file** are used to specify the database.
- d. In the left side of the dialog box, click **All** to view additional settings for this connection, including all default settings for this provider.
- e. Change settings as appropriate for your environment and then click **OK**.

The new connection appears in the **Data Connection** pane of the **Select how to define the connection** page of the Data Source Wizard.

6. Click **Next**.
7. In **Impersonation Information**, specify the Windows credentials or user identity that Analysis Services will use when connecting to the external data source. If you are using database authentication, these settings are ignored for connection purposes.

Guidelines for choosing an impersonation option vary depending on how you are using the data source. For processing tasks, the Analysis Services service must run in the security context of its service account or

a specified user account when connecting to a data source.

- **Use a specific Windows user name and password** to specify a unique set of least privilege credentials.
- **Use the service account** to process the data using the service identity.

The account you specify must have Read permissions on the data source.

8. Click **Next**. In **Completing the Wizard**, enter a data source name or use the default name. The default name is the name of the database specified in the connection. The **Preview** pane displays the connection string for this new data source.
9. Click **Finish**. The new data source appears in the **Data Sources** folder in Solution Explorer.

Create a Data Source Using an Existing Connection

When you work in an Analysis Services project, your data source can be based on an existing data source in your solution or can be based on an Analysis Services project. The Data Source Wizard provides several options for creating the data source object, including using an existing connection in the same project.

- Creating a data source based on an existing data source in your solution lets you define a data source that is synchronized with the existing data source. When the project containing this new data source is built, the data source settings from the underlying data source are used.
- Creating a data source based on an Analysis Services project lets you reference another Analysis Services project in the solution in the current project. The new data source uses the MSOLAP provider with its **Data Source** property and **Initial Catalog** property acquired from the **TargetServer** and **TargetDatabase** properties of the selected project. This feature is useful in solutions where you are using multiple Analysis Services projects to manage remote partitions, because the source and destination Analysis Services databases require reciprocal data sources to support remote partition storage and processing.

When you reference a data source object, you can edit that object only in the referenced object or project. You cannot edit the connection information in the data source object that contains the reference. Changes to the connection information in the referenced object or project appear in the new data source when it is built. The connection string information that appears in the data source (.ds) file in the project is synchronized when you build the project or when you clear the reference in Data Source Designer.

View or Edit Connection Properties

The connection string is formulated based on the properties you select in the Data Source Designer or the New Data Source Wizard. You can view the connection string and other properties in Visual Studio with Analysis Services projects.

To edit the connection string

1. In Visual Studio with Analysis Services projects, double-click the data source object in Solution Explorer.
2. Click **Edit**, and then click **All** on the left navigation pane.
3. The property grid appears, showing available properties of the data provider you are using. For more information about these properties, see the product documentation of the provider. For SQL Server native client, see [Using Connection String Keywords with SQL Server Native Client](#).

If you have multiple data source objects in the solution and you prefer to maintain the connection string in one place, you can configure the current data source to reference the other data source object.

A *data source reference* is an association to another Analysis Services project or data source in the same solution. References provide a means to synchronize data sources between objects in a solution. The connection string information is synchronized whenever you build the project. To change the connection string for a data source that references another object, you must change the connection string of the referenced object.

You can remove the reference by clearing the check box. This ends the synchronization between the objects and lets you change the connection string in the data source.

Add Multiple Data Sources to a Model

You can create more than one data source object to support connections to additional data sources. Each data source must have columns that can be used to create relationships.

NOTE

If multiple data sources are defined and data is queried from multiple sources in a single query, such as for a snow-flaked dimension, you must define a data source that supports remote queries using **OpenRowset**. Typically, this will be a Microsoft SQL Server data source.

Requirements for using multiple data sources include the following:

- Designate one data source as the primary data source. The primary data source is the one used to create a data source view.
- A primary data source must support the **OpenRowset** function. For more information about this function in SQL Server, see [OpenRowSet](#).

Use the following approach to combine data from multiple data sources:

1. Create the data sources in your model.
2. Create a data source view, using a SQL Server relational database as the data source. This is your primary data source.
3. In Data Source View Designer, using the data source view you just created, right-click anywhere in the work area and select **Add/Remove Tables**.
4. Choose the second data source and then select the tables you want to add.
5. Find and select the table you added. Right-click the table and select **New Relationship**. Choose the source and destination columns that contain matching data.

[Supported Data Sources \(SSAS - Multidimensional\)](#)

[Data Source Views in Multidimensional Models](#)

Delete a Data Source in Solution Explorer (SSAS Multidimensional)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can delete a data source object to permanently remove it from an Analysis Services multidimensional model project.

In Analysis Services, data sources provide the basis on which data source views are constructed, and data source views are in turn used to define dimensions, cubes, and mining structures in an Analysis Services project or database. Therefore, deleting a data source may invalidate other Analysis Services objects in an Analysis Services project. You should always review the list of dependent objects that is provided before deleting the object.

IMPORTANT

Data sources on which other objects depend cannot be deleted from an Analysis Services database opened by Visual Studio with Analysis Services projects in online mode. You must delete all objects in the Analysis Services database that depend on that data source before deleting the data source. For more information about online mode, see [Connect in Online Mode to an Analysis Services Database](#).

To delete a data source

1. In Visual Studio with Analysis Services projects, open the project or connect to the database from which you want to delete a data source.
2. In **Solution Explorer**, expand the **Data Sources** folder.
3. Right-click the data source, and then click **Delete**. The **Delete Objects** dialog box appears, showing the objects that will be invalidated if you delete the data source. Review this list carefully before clicking **OK** to delete the data source.
4. Save the project.

After deleting a data source from an Analysis Services project, you must save the modified project or you will receive an error the next time you open the project because the underlying XML file for the deleted data source will be missing when the project attempts to load the deleted data source.

Set Data Source Properties (SSAS Multidimensional)

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Analysis Services, a data source object specifies a connection to an external data warehouse or relational database that provides data to a multidimensional model. Properties on the data source determine the connection string, a timeout interval, maximum number of connections, and the transaction isolation level.

Set data source properties in SQL Server Data Tools

1. Double-click a data source in Solution Explorer to open Data Source Designer.
2. Click the **Impersonation Information** tab in Data Source Designer. For more information about creating a data source, see [Create a Data Source \(SSAS Multidimensional\)](#).

Set data source properties in Management Studio

1. Expand the database folder, open the **Data Source** folder under the database name, right-click a data source in **Object Explorer** and select **Properties**.
2. Optionally, modify the name, description, or impersonation option. For more information, see [Set Impersonation Options \(SSAS - Multidimensional\)](#).

Data Source properties

| TERM | DEFINITION |
|------------------------------|---|
| Name, ID, Description | Name, ID, and Description are used to identify and describe the data source object in the multidimensional model.

Name and Description can be specified in Visual Studio with Analysis Services projects or in Management Studio after you deploy or process the solution.

ID is generated when the object is created. Although you can easily modify the name and description, IDs are read-only and should not be changed. A fixed object ID preserves object dependencies and references throughout the model. |
| Create Timestamp | This read-only property appears in Management Studio. It displays the date and time the data source was created. |
| Last Schema Update | This read-only property appears in Management Studio. It displays the date and time the metadata for the data source was last updated. This value is updated when you deploy the solution. |

| TERM | DEFINITION |
|--------------------------------------|---|
| Query Timeout | <p>Specifies how long a connection request will be attempted before it is dropped.</p> <p>Type the query timeout in the following format:</p> <p><i><Hours>:<Minutes>:<Seconds></i></p> <p>This property can be overruled by the DatabaseConnectionPoolTimeout server property. If the server property is smaller, it will be used instead of Query Timeout.</p> <p>For more information about the Query Timeout property, see Timeout. For more information about the server property, see OLAP Properties.</p> |
| Connection String | <p>Specifies the physical location of a database that provides data to a multidimensional model, and the data provider used for the connection. This information is provided to a client library making the connection request. The provider determines which properties can be set on the connection string.</p> <p>The connection string is built using the information you provide in the Connection Manager dialog box. You can also view and edit the connection string in Management Studio in the data source property page.</p> <p>For a SQL Server database, a connection string that contains user ID indicates database authentication; a connection containing Integrated Security=SSPI indicates Windows authentication.</p> <p>You can change the server or database name if the database was moved to a new location. Be sure to verify that the credentials currently specified for the connection are mapped to a database login.</p> |
| Maximum number of connections | <p>Specifies the maximum number of connections allowed by Analysis Services to connect to the data source. If more connections are needed, Analysis Services will wait until a connection becomes available. The default is 10. Constraining the number of connections ensures that the external data source is not overloaded with Analysis Services requests.</p> |
| Isolation | <p>Specifies the locking and row versioning behavior of SQL commands issued by a connection to a relational database. Valid values are ReadCommitted or Snapshot. The default is ReadCommitted, which specifies that data must be committed before it will be read, preventing dirty reads. Snapshot specifies that reads are from a snapshot of previously committed data. For more information about isolation level in SQL Server, see SET TRANSACTION ISOLATION LEVEL (Transact-SQL).</p> |

| TERM | DEFINITION |
|---------------------------|---|
| Managed Provider | <p>Displays the name of the managed provider, such as System.Data.SqlClient or System.Data.OracleClient, if the data source uses a managed provider.</p> <p>If the data source does not use a managed provider, this property displays an empty string.</p> <p>This property is read-only in Management Studio. To change the provider used on the connection, edit the connection string.</p> |
| Impersonation Info | <p>Specifies the Windows identity that Analysis Services runs under when connecting to a data source that uses Windows authentication. Options include using a predefined set of Windows credentials, the service account, the identity of the current user, or an inherit option that can be useful if your model contains multiple data source objects. For more information, see Set Impersonation Options (SSAS - Multidimensional).</p> <p>In Management Studio, the valid values list includes these values:</p> <ul style="list-style-type: none"> ImpersonateAccount (use a specific Windows user name and password to connect to the data source). ImpersonateServiceAccount (use the security identity of the service account to connect to the data source). This is the default value. ImpersonateCurrentUser (use the security identity of the current user to connect to the data source). This option is only valid for data mining queries that retrieve data from an external data warehouse or database; do not choose it for data connections used for processing, loading, or write-back in a multidimensional database. Inherit or default (use the impersonation settings of the Analysis Services database that contains this data source object). Database properties include impersonation options. |

Set Impersonation Options (SSAS - Multidimensional)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When creating a **data source** object in an Analysis Services model, one of the settings that you must configure is an impersonation option. This option determines whether Analysis Services assumes the identity of a specific Windows user account when performing local operations related to the connection, such as loading an OLE DB data provider or resolving user profile information in environments that support roaming profiles.

For connections that use Windows authentication, the impersonation option also determines the user identity under which queries execute on the external data source. For example, if you set the impersonation option to **contoso\dbuser**, queries used to retrieve data during processing will execute as **contoso\dbuser** on the database server.

This topic explains how to set impersonation options in the **Impersonation Information** dialog box when configuring a data source object.

Set impersonation options in SQL Server Data Tools

1. Double-click a data source in Solution Explorer to open Data Source Designer.
2. Click the **Impersonation Information** tab in Data Source Designer.
3. Choose an option described in [Impersonation options](#) in this topic.

Set impersonation options in Management Studio

In Management Studio, open the **Impersonation Information** dialog box by clicking the ellipsis (...) button for the following properties of these dialog boxes:

- **Database Properties** dialog box, through the Data Source Impersonation Info property.
- **Data Source Properties** dialog box, through the Impersonation Info property.
- **Assembly Properties** dialog box, through the Impersonation Info property.

Impersonation options

All options are available in the dialog box, but not all options are appropriate for every scenario. Use the following information to determine the best option for your scenario.

Use a specific user name and password

Select this option to have the Analysis Services object use the security credentials of a Windows user account specified in this format: <Domain name>\<User account name>.

Choose this option to use a dedicated, least-privilege Windows user identity that you have created specifically for data access purposes. For example, if you routinely create a general purpose account for retrieving data used in reports, you can specify that account here.

For multidimensional databases, the specified credentials will be used for processing, ROLAP queries, out-of-line bindings, local cubes, mining models, remote partitions, linked objects, and synchronization from target to

source.

For DMX OPENQUERY statements, this option is ignored and the credentials of the current user will be used rather than the specified user account.

Use the service account

Select this option to have the Analysis Services object use the security credentials associated with the Analysis Services service that manages the object. This is the default option. In previous releases, this was the only option you could use. You might prefer this option to monitor data access at the service level rather than individual user accounts.

In SQL Server 2017, depending on the operating system you are using, the service account might be NetworkService or a built-in virtual account created for a specific Analysis Services instance. If you choose the service account for a connection that uses Windows authentication, remember to create a database login for this account and grant read permissions, as it will be used to retrieve data during processing. For more information about the service account, see [Configure Windows Service Accounts and Permissions](#).

NOTE

When using database authentication, you should choose the **Use the service account** impersonation option if the service is running under the dedicated virtual account for Analysis Services. This account will have permissions to access local files. If the service runs as NetworkService, a better alternative is to use a least privilege Windows user account that has **Allow log on locally** permissions. Depending on the account you provide, you might also need to grant file access permissions on the Analysis Services program folder.

For multidimensional databases, the service account credentials will be used for processing, ROLAP queries, remote partitions, linked objects, and synchronization from target to source.

For DMX OPENQUERY statements, local cubes, and mining models, the credentials of the current user will be used even if you choose the service account option. The service account option is not supported for out-of-line bindings.

NOTE

Errors can occur when processing a data mining model from a cube if the service account does not have administrator permissions on the Analysis Services instance. For more information, see [Mining Structure: Issue while Processing when DataSource is OLAP Cube](#).

Use the credentials of the current user

Select this option to have the Analysis Services object use the security credentials of the current user for out-of-line bindings, DMX OPENQUERY, local cubes, and mining models.

With the exception of local cubes and processing using out-of-line bindings, this option is not supported for multidimensional databases.

Default or Inherit

The dialog box uses **Default** for the impersonation options set at the database level and **Inherit** for impersonation options set at the data source level.

Data Sources - Inherit Option

At the data source level, **Inherit** specifies that Analysis Services should use the impersonation option of the parent object. In a multidimensional model, the parent object is the Analysis Services database. Choosing the **Inherit** option lets you centrally manage the impersonation settings for this and other data sources that are part of the same database. For this option to be meaningful, choose a specific Windows user name and password at the database level. Otherwise, the combination of **Inherit** on the data source and **Default** on the database are

equivalent to using service account option.

To specify a Windows user name and password at the database level, do the following:

1. Right-click the database in Management Studio and select **Properties**.
2. In **Data Source Impersonation Info**, specify a Windows user name and password.
3. Right-click each data source and view its properties to ensure that each one is using the **Inherit** option.

For more information about default settings at the database level, see [Set Multidimensional Database Properties \(Analysis Services\)](#).

Databases - Default option

For multidimensional databases, **Default** means use the service account, and current user for data mining operations.

Data Source Views in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A data source view (DSV) is an abstraction of a relational data source that becomes the basis of the cubes and dimensions you create in a multidimensional project. The purpose of a DSV is to give you control over the data structures used in your project, and to work independently of the underlying data sources (for example, the ability to rename or concatenate columns without directly modifying the original data source).

You can build multiple data source views in an Analysis Services project or database on one or more data sources, and construct each one to satisfy the requirements for a different solution.

Data Sources and Bindings (SSAS Multidimensional)

7/16/2019 • 13 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Cubes, dimensions, and other Analysis Services objects can be bound to a data source. A data source can be one of the following objects:

- A relational data source.
- An Analysis Services pipeline that outputs a rowset (or chaptered rowsets).

The means of expressing the data source varies by the type of data source. For example, a relational data source is distinguished by the connection string. For more information about data sources, see [Data Sources in Multidimensional Models](#).

Regardless of the data source used, the data source view (DSV) contains the metadata for the data source. Thus, the bindings for a cube or other Analysis Services objects are expressed as bindings to the DSV. These bindings can include bindings to logical objects—objects such as views, calculated columns, and relationships that do not physically exist in the data source. Analysis Services adds a calculated column that encapsulates the expression to the DSV, and then binds the corresponding OLAP measure to that column in the DSV. For more information about DSVs, see [Data Source Views in Multidimensional Models](#).

Each Analysis Services object binds to the data source in its own way. In addition, the data bindings for these objects and the definition of the data source can be provided inline with the definition of the databound object (for example, the dimension), or out-of-line as a separate set of definitions.

Analysis Services Data Types

The data types that are used in bindings must match the data types supported by Analysis Services. The following data types are defined in Analysis Services:

| ANALYSIS SERVICES DATA TYPE | DESCRIPTION |
|-----------------------------|--|
| BigInt | A 64-bit signed integer. This data type maps to the Int64 data type inside Microsoft .NET Framework and the DBTYPE_I8 data type inside OLE DB. |
| Bool | A Boolean value. This data type maps to the Boolean data type inside the .NET Framework and the DBTYPE_BOOL data type inside OLE DB. |
| Currency | A currency value ranging from -263 (or -922,337,203,685,477.5808) to 263-1 (or +922,337,203,685,477.5807) with an accuracy to a ten-thousandth of a currency unit. This data type maps to the Decimal data type inside the .NET Framework and the DBTYPE_CY data type inside OLE DB. |

| ANALYSIS SERVICES DATA TYPE | DESCRIPTION |
|-----------------------------|---|
| Date | Date data, stored as a double-precision floating-point number. The whole portion is the number of days since December 30, 1899, while the fractional portion is a fraction of a day. This data type maps to the DateTime data type inside the .NET Framework and the DBTYPE_DATE data type inside OLE DB. |
| Double | A double-precision floating-point number within the range of -1.79E +308 through 1.79E +308. This data type maps to the Double data type inside the .NET Framework and the DBTYPE_R8 data type inside OLE DB. |
| Integer | A 32-bit signed integer. This data type maps to the Int32 data type inside the .NET Framework and the DBTYPE_I4 data type inside OLE DB. |
| Single | A single-precision floating-point number within the range of -3.40E +38 through 3.40E +38. This data type maps to the Single data type inside .NET Framework and the DBTYPE_R4 data type inside OLE DB. |
| SmallInt | A 16-bit signed integer. This data type maps to the Int16 data type inside the .NET Framework and the DBTYPE_I2 data type inside OLE DB. |
| TinyInt | An 8-bit signed integer. This data type maps to the SByte data type inside the .NET Framework and the DBTYPE_I1 data type inside OLE DB.

Note: If a data source contains fields that are of the tinyint datatype and the AutoIncrement property is set to True, then they will be converted to integers in the data source view. |
| UnsignedBigInt | A 64-bit unsigned integer. This data type maps to the UInt64 data type inside .NET Framework and the DBTYPE_UI8 data type inside OLE DB. |
| UnsignedInt | A 32-bit unsigned integer. This data type maps to the UInt32 data type inside the .NET Framework and the DBTYPE_UI4 data type inside OLE DB. |
| UnsignedSmallInt | A 16-bit unsigned integer. This data type maps to the UInt16 data type inside the .NET Framework and the DBTYPE_UI2 data type inside OLE DB. |
| WChar | A null-terminated stream of Unicode characters. This data type maps to the String data type inside the .NET Framework and the DBTYPE_WSTR data type inside OLE DB. |

All data that is received from the data source is converted to the SSAS type specified in the binding (usually during processing). An error is raised if the conversion cannot be performed (for example, String to Int). Visual Studio with Analysis Services projects usually sets the data type in the binding to the one that best matches the source type in the data source. For example, the SQL types Date, DateTime, SmallDateTime, DateTime2, DateTimeOffset are mapped to SSAS Date, and the SQL type Time is mapped to String.

Bindings for Dimensions

Each attribute of a dimension is bound to a column in a DSV. All the attributes of a dimension must come from a single data source. However, the attributes can be bound to columns in different tables. The relationships between the tables are defined in the DSV. In the case where more than one set of relationships exists to the same table, it might be necessary to introduce a named query in the DSV to act as an 'alias' table. Expressions and filters are defined in the DSV by using named calculations and named queries.

Bindings for MeasureGroups, Measures, and Partitions

Each measure group has the following default bindings:

- The measure group is bound to a table in a DSV (for example, **MeasureGroup.Source**).
- Each measure is bound to a column in that table (for example, **Measure.ValueColumn.Source**).
- Each measure group dimension has a set of *granularity attributes* that define the granularity of the measure group. Each of these attributes must be bound to the column or columns in the fact table that contain the attribute key. (For more information about granularity attributes, see MeasureGroup Granularity Attributes later in this topic.)

These default bindings can be selectively overridden per partition. Each partition can specify a different data source, table or query name, or filter expression. The most common partitioning strategy is to override the table per partition, by using the same data source. Alternatives include applying a different filter per partition or changing the data source.

The default data source must be defined in the DSV, thereby providing the schema information, including the details of relationships. Any additional tables or queries specified at the partition level do not need to be listed in the DSV, but they must have the same schema as the default table defined for the measure group, or at least they must contain all the columns used by the measures or granularity attributes. The detailed bindings per measure and granularity attribute cannot be overridden at the partition level, and they are assumed to be to the same columns as defined for the measure group. Therefore, if the partition uses a data source that does in fact have a different schema, the **TableDefinition** query defined for the partition must result in the same schema as the schema used by the measure group.

MeasureGroup Granularity Attributes

When the granularity of a measure group matches the granularity known in the database, and there is a direct relationship from the fact table to the dimension table, the granularity attribute only needs to be bound to the appropriate foreign key column or columns on the fact table. For example, consider the following fact and dimension tables:

```
Sales(RequestedDate, OrderedProductID, ReplacementProductID, Qty)
```

```
Product(ProductID, ProductName, Category)
```

..

```
Relation: Sales.OrderedProductID -> Product.ProductID
```

```
Relation: Sales.ReplacementProductID -> Product.ProductID
```

..

If you analyze by the ordered product, for the Ordered Product on Sales dimension role, the Product granularity attribute would be bound to Sales.OrderedProductID.

However, there may be times when the **GranularityAttributes** might not exist as columns on the fact table. For example, the **GranularityAttributes** might not exist as columns in the following circumstances:

- The OLAP granularity is coarser than the granularity in the source.
- An intermediate table interposes between the fact table and the dimension table.
- The dimension key is not the same as the primary key in the dimension table.

In all such cases, the DSV must be defined so that the GranularityAttributes exist on the fact table. For example, a named query or calculated column can be introduced.

For example, in the same example tables as above, if the granularity were by Category, then a view of the Sales could be introduced:

```
SalesWithCategory(RequestedDate, OrderedProductID, ReplacementProductID, Qty, OrderedProductCategory)
```

```
SELECT Sales.* , Product.Category AS OrderedProductCategory
```

```
FROM Sales INNER JOIN Product
```

```
ON Sales.OrderedProductID = Product.ProductID
```

```
..
```

In this case, the GranularityAttribute Category is bound to SalesWithCategory.OrderedProductCategory.

Migrating from Decision Support Objects

Decision Support Objects (DSO) 8.0 allows **PartitionMeasures** to be rebound. Therefore, the migration strategy in these cases is to construct the appropriate query.

Similarly, it is not possible to rebind the dimension attributes within a partition, although DSO 8.0 allows this rebinding also. The migration strategy in these cases is to define the necessary named queries in the DSV so that the same tables and columns exist in the DSV for the partition as the tables and columns that are used for the dimension. These cases may require the adoption of the simple migration, in which the From/Join/Filter clause is mapped to a single named query rather than to a structured set of related tables. As DSO 8.0 allows PartitionDimensions to be rebound even when the partition is using the same data source, migration may also require multiple DSVs for the same data source.

In DSO 8.0, the corresponding bindings can be expressed in two different ways, depending on whether optimized schemas are employed, by binding to either the primary key on the dimension table or the foreign key on the fact table. In ASSL, the two different forms are not distinguished.

The same approach to bindings applies even for a partition using a data source that does not contain the dimension tables, because the binding is made to the foreign key column in the fact table, not to the primary key column in the dimension table.

Bindings for Mining Models

A mining model is either relational or OLAP. The data bindings for a relational mining model are considerably different than the bindings for an OLAP mining model.

Bindings for a Relational Mining Model

A relational mining model relies on the relationships defined in the DSV to resolve any ambiguity regarding which columns are bound to which data sources. In a relational mining model, the data bindings follow these rules:

- Each non-nested table column is bound to a column either on the case table or a table related to the case table (following a many-to-one or one-to-one relationship). The DSV defines the relationships between the tables.
- Each nested-table column is bound to a source table. The columns owned by the nested-table column are then bound to columns on that source table or a table related to the source table. (Again, the binding

follows a many-to-one or one-to-one relationship.) The mining model bindings do not provide the join path to the nested table. Instead, the relationships defined in the DSV provide this information.

Bindings for an OLAP Mining Model

OLAP mining models do not have the equivalent of a DSV. Therefore, the data bindings must provide any disambiguation between columns and data sources. For example, a mining model can be based on the Sales cube, and columns can be based on Qty, Amount, and Product Name. Alternatively, a mining model can be based on Product, and columns can be based on Product Name, Product Color, and a nested table with Sales Qty.

In an OLAP mining model, the data bindings follow these rules:

- Each non-nested table column is bound to a measure on a cube, to an attribute on a dimension of that cube (specifying the **CubeDimension** to disambiguate in the case of dimension roles), or to an attribute on a dimension.
- Each nested table column is bound to a **CubeDimension**. That is, it defines how to navigate from a dimension to a related cube or (in the less common case of nested tables) from a cube to one of its dimensions.

Out-of-Line Bindings

Out-of-Line bindings enable you to temporarily change the existing data bindings for the duration of a command. Out-of-line bindings refer to bindings that are included in a command and are not persisted. Out-of-line bindings apply only while that particular command executes. In contrast, inline bindings are contained in the ASSL object definition, and persist with the object definition within server metadata.

ASSL allows out-of-line bindings to be specified on either a **Process** command, if it is not in a batch, or on a **Batch** command. If out-of-line bindings are specified on the **Batch** command, all bindings specified in the **Batch** command create a new binding context in which all **Process** commands of the batch run. This new binding context includes objects that are indirectly processed because of the **Process** command.

When out-of-line bindings are specified on a command, they override the inline bindings contained in the persisted DDL for the specified objects. These processed objects may include the object directly named in the **Process** command, or they may include other objects whose processing is automatically initiated as a part of the processing.

Out-of-line bindings are specified by including the optional **Bindings** collection object with the processing command. The optional **Bindings** collection contains the following elements.

| PROPERTY | CARDINALITY | TYPE | DESCRIPTION |
|-----------------------|-------------|-----------------------|---|
| Binding | 0-n | Binding | Provides a collection of new bindings. |
| DataSource | 0-1 | DataSource | Replaces DataSource from server that would have been used. |
| DataSourceView | 0-1 | DataSourceView | Replaces the DataSourceView from the server that would have been used. |

All elements that relate to out-of-line bindings are optional. For any elements not specified, ASSL uses the specification contained in the DDL of the persisted object. Specification of **DataSource** or **DataSourceView** in the **Process** command is optional. If **DataSource** or **DataSourceView** are specified, they are not instantiated

and do not persist after the **Process** command has completed.

Definition of the Out-of-line Binding Type

Inside the out-of-line **Bindings** collection, ASSL allows a collection of bindings for multiple objects, each a **Binding**. Each **Binding** has an extended object reference, which is similar to the object reference, but it can refer to minor objects as well (for example, dimension attributes and measure group attributes). This object takes the flat form typical of the **Object** element in **Process** commands, except that the `<Object></Object>` tags are not present.

Each object for which the binding is specified is identified by an XML element of the form `<object>ID` (for example, **DimensionID**). After you have identified the object as specifically as possible with the form `<object>ID`, then you identify the element for which the binding is being specified, which is usually **Source**. A common case to note is that in which **Source** is a property on the **DataItem**, which is the case for column bindings in an attribute. In this case, you do not specify the **DataItem** tag; instead, you simply specify the **Source** property, as if it were directly on the column to be bound.

KeyColumns are identified by their ordering inside the **KeyColumns** collection. There it is not possible to specify, for example, only the first and third key columns of an attribute, because there is no way to indicate that the second key column is to be skipped. All of the key columns must be present in the out-of-line binding for a dimension attribute.

Translations, although they have no ID, are semantically identified by their language. Therefore, the **Translations** inside a **Binding** need to include their language identifier.

One additional element allowed within a **Binding** that does not exist directly in the DDL is **ParentColumnID**, which is used for nested tables for data mining. In this case, it is necessary to identify the parent column in the nested table for which the binding is being provided.

Defining a Data Source View (Analysis Services)

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

A data source view contains the logical model of the schema used by Analysis Services multidimensional database objects—namely cubes, dimensions, and mining structures. A data source view is the metadata definition, stored in an XML format, of these schema elements used by the Unified Dimensional Model (UDM) and by the mining structures. A data source view:

- Contains the metadata that represents selected objects from one or more underlying data sources, or the metadata that will be used to generate an underlying relational data store if you are following the top-down approach to schema generation.
- Can be built over one or more data sources, letting you define multidimensional and data mining objects that integrate data from multiple sources.
- Can contain relationships, primary keys, object names, calculated columns, and queries that are not present in an underlying data source and which exist separate from the underlying data sources.
- Is not visible to or available to be queried by client applications.

A DSV is a required component of a multidimensional model. Most Analysis Services developers create a DSV during the early phases of model design, generating at least one DSV based on an external relational database that provides underlying data. However, you can also create the DSV at a later phase, generating the schema and underlying database structures after the dimensions and cubes are created. This second approach is sometimes called top-down design and is frequently used for prototyping and analysis modeling. When you use this approach, you use the Schema Generation Wizard to create the underlying data source view and data source objects based on the OLAP objects defined in an Analysis Services project or database. Regardless of how and when you create a DSV, every model must have one before you can process it.

This topic includes the following sections:

[Data Source View Composition](#)

[Create a DSV Using the Data Source View Wizard](#)

[Specify Name Matching Criteria for Relationships](#)

[Add a Secondary Data Source](#)

Data Source View Composition

A data source view contains the following items:

- A name and a description.
- A definition of any subset of the schema retrieved from one or more data sources, up to and including the whole schema, including the following:
 - Table names.
 - Column names.
 - Data types.

- Nullability.
- Column lengths.
- Primary keys.
- Primary key - foreign key relationships.
- Annotations to the schema from the underlying data sources, including the following:
 - Friendly names for tables, views, and columns.
 - Named queries that return columns from one or more data sources (that show as tables in the schema).
 - Named calculations that return columns from a data source (that show as columns in tables or views).
 - Logical primary keys (needed if a primary key is not defining in the underlying table or is not included in the view or named query).
 - Logical primary key - foreign key relationships between tables, views, and named queries.

Create a DSV Using the Data Source View Wizard

To create a DSV, run the Data Source View Wizard from Solution Explorer in Visual Studio with Analysis Services projects.

NOTE

Alternatively, you can construct dimensions and cubes first, and then generate a DSV for the model using the Schema Generation wizard. For more information, see [Schema Generation Wizard \(Analysis Services\)](#).

1. In Solution Explorer, right-click the Data Source Views folder and then click **New Data Source View**.
2. Specify a new or existing data source object that provides connection information to an external relational database (you can only select one data source in the wizard).
3. On the same page, click **Advanced** to choose specific schemas, apply a filter, or exclude table relationship information.

Choose Schemas

For very large data sources containing multiple schemas, you can select which schemas to use in a comma delimited list, with no spaces.

Retrieve Relationships

You can purposely omit table relationship information by clearing the **Retrieve relationships** checkbox in the Advanced Data Source View Options dialog box, allowing you to manually create relationships between tables in the Data Source View Designer.

4. Filter Available Objects

If the Available objects list contains a very large number of objects, you can reduce the list by applying a simple filter that specifies a string as selection criteria. For example, if you type **dbo** and click the **Filter** button, then only those items starting with "dbo" show up in the **Available objects** list. The filter can be a partial string (for example, "sal" returns sales and salary) but it cannot include multiple strings or operators.

5. For relational data sources that do not have table relationships defined, a **Name Matching** page appears

so that you can select the appropriate name matching method. For more information, see the [Specify Name Matching Criteria for Relationships](#) section in this topic.

Add a Secondary Data Source

When defining a data source view that contains tables, views, or columns from multiple data sources, the first data source from which you add objects to the data source view is designated as the primary data source (you cannot change the primary data source after it is defined). After defining a data source view based on objects from a single data source, you can then add objects from other data sources.

If an OLAP processing or a data mining query requires data from multiple data sources in a single query, the primary data source must support remote queries using **OpenRowset**. Typically, this will be a SQL Server data source. For example, if you design an OLAP dimension that contains attributes that are bound to columns from multiple data sources, then Analysis Services will construct an **OpenRowset** query to populate this dimension during processing. However, if an OLAP object can be populated or a data mining query resolved from a single data source, then an **OpenRowset** query will not be constructed. In certain situations, you may be able to define attribute relationships between attributes to eliminate the need for an **OpenRowset** query. For more information about attribute relationships, see [Attribute Relationships, Adding or Removing Tables or Views in a Data Source View \(Analysis Services\)](#) and [Define Attribute Relationships](#).

To add tables and columns from a second data source, you double-click the DSV in Solution Explorer to open it in Data Source View Designer, and then use Add/Remove Tables dialog box to include objects from other data sources that are defined in your project. For more information, see [Adding or Removing Tables or Views in a Data Source View \(Analysis Services\)](#).

Specify Name Matching Criteria for Relationships

When you create a DSV, relationships are created between tables based on foreign key constraints in the data source. These relationships are required for the Analysis Services engine to construct the appropriate OLAP processing and data mining queries. Sometimes, however, a data source with multiple tables has no foreign key constraints. If a data source has no foreign key constraints, the Data Source View Wizard prompts you to define how you want the wizard to attempt to match column names from different tables.

NOTE

You are prompted to provide name matching criteria only if no foreign key relationships are detected in the underlying data source. If foreign key relationships are detected, then the detected relationships are used and you must manually define any additional relationships you want to include in the DSV, including logical primary keys. For more information, see [Define Logical Relationships in a Data Source View \(Analysis Services\)](#) and [Define Logical Primary Keys in a Data Source View \(Analysis Services\)](#).

The Data Source View Wizard uses your response to match column names and create relationships between different tables in the DSV. You can specify any one of the criteria listed in the following table.

| NAME MATCHING CRITERIA | DESCRIPTION |
|---------------------------------|---|
| Same name as primary key | The foreign key column name in the source table is the same as the primary key column name in the destination table. For example, the foreign key column <code>Order.CustomerID</code> is the same as the primary key column <code>Customer.CustomerID</code> . |

| NAME MATCHING CRITERIA | DESCRIPTION |
|--|--|
| Same name as destination table name | The foreign key column name in the source table is the same as the name of the destination table. For example, the foreign key column <code>Order.Customer</code> is the same as the primary key column <code>Customer.CustomerID</code> . |
| Destination table name + primary key name | The foreign key column name in the source table is the same as the destination table name concatenated with the primary key column name. A space or underscore separator is permissible. For example, the following foreign-primary key pairs all match:

<code>Order.CustomerID</code> and <code>Customer.ID</code>

<code>Order.Customer_ID</code> and <code>Customer.ID</code>

<code>Order.Customer_ID</code> and <code>Customer.ID</code> |

The criteria you select changes the **NameMatchingCriteria** property setting of the DSV. This setting determines how the wizard adds related tables. When you change the data source view with Data Source View Designer, this specification determines how the designer matches columns to create relationships between tables in the DSV. You can change the **NameMatchingCriteria** property setting in Data Source View Designer. For more information, see [Change Properties in a Data Source View \(Analysis Services\)](#).

NOTE

After you complete the Data Source View Wizard, you can add or remove relationships in the schema pane of Data Source View Designer. For more information, see [Define Logical Relationships in a Data Source View \(Analysis Services\)](#).

Adding or Removing Tables or Views in a Data Source View (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you have created a data source view (DSV) in Visual Studio with Analysis Services projects, you can modify it in Data Source View Designer by adding or removing tables and columns, including tables and columns from another data source.

To open the DSV in Data Source View Designer, you double-click the DSV in Solution Explorer. Once you open the DSV, you can use the **Add/Remove Tables** command on the button bar or menu to modify or extend the DSV. You can also work with the objects in the diagram. For example, you can select an object and then use the Delete key on your keyboard to remove an object.

WARNING

Use caution when removing a table. Removing a table deletes all the associated columns and relationships from the DSV and invalidates all objects bound to that table.

Selecting Tables or Views to Add or Remove

Using the **Add/Remove Tables** dialog box, you can move tables or views between the **Available objects** and **Included objects** lists. The **Available objects** list initially includes any tables or views in the primary data source that are not already in the data source view. If the primary data source supports the **OPENROWSET** function, you can also add tables or views from other data sources in the project or database.

Adding or removing a table to the DSV also adds or removes the table to the currently selected diagram in the DSV. For more information on diagrams, see [Work with Diagrams in Data Source View Designer \(Analysis Services\)](#).

After you move a table to the **Included objects** list in the **Add/Remove Tables** dialog box, you can add all related tables. This operation adds tables according to foreign key constraints in the data source, if such constraints exist. If foreign key constraints do not exist, you can use the **NameMatchingCriteria** property of the data source view to determine relationships by specifying a criterion for matching column names in tables to generate likely relationships. If the **NameMatchingCriteria** property is specified for the data source view, click **Add Related Tables** to add tables from the data source that have matching column names. For more information about setting the **NameMatchingCriteria** property, see [Data Source Views in Multidimensional Models](#).

NOTE

Adding or removing objects in a data source view does not affect the underlying data source.

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can use the **Explore Data** dialog box in Data Source View Designer in Visual Studio with Analysis Services projects to browse data for a table, view, or named query in a data source view (DSV). When you explore the data in Data Source View Designer, you can view the contents of each column of data in a selected table, view, or named query. Viewing the actual contents assists you in determining whether all columns are needed, if named calculations are required to increase user friendliness and usability, and whether existing named calculations or named queries return the anticipated values.

To view data, you must have an active connection to the data source or sources for the selected object in the DSV. Any named calculations in a table are also sent in the query.

The data returned in a tabular format that you can sort and copy. Click on the column headers to re-sort the rows by that column. You can also highlight data in the grid and press Ctrl-C to copy the selection to the clipboard.

You can also control the sample method and the sample count. By default, the top 5000 rows are returned.

To browse data or change sampling options

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you want to browse data.
2. In Solution Explorer, expand the **Data Source Views** folder, and then double-click the data source view.
3. Right-click the table, view, or named query that contains the data you want to view, and then click **Explore Data**.

The data source underlying the table, view, or named query in the data source view are queries, and the results appear in the **Explore <object name> Table** tab.

4. On the **Explore <object name> Table** toolbar, click the **Sampling options** icon.

The **Data Exploration Options** dialog box opens. In this dialog box you can specify the sampling method (fewer or more records than the default sampling size of 5000 rows), or sample count.

5. Click **OK** or **Cancel** as appropriate.
6. To resample the data, click **Resample Data** on the **Explore <object name> Table** toolbar.

Work with Diagrams in Data Source View Designer (Analysis Services)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A data source view (DSV) diagram is a visual representation of the objects in a DSV. You can work with the diagram interactively to add, hide, delete or modify specific objects. You can also create multiple diagrams on the same DSV to focus attention on a subset of the objects.

To change the area of the diagram that appears in the diagram pane, click the four-headed arrow in the lower right corner of the pane, and then drag the selection box over the thumbnail diagram until you select the area that is to appear in the diagram pane.

This topic includes the following sections:

[Add a Diagram](#)

[Edit or Delete a Diagram](#)

[Find Tables in a Diagram](#)

[Arrange Objects in a Diagram](#)

[Preserve object arrangement](#)

Add a Diagram

DSV diagrams are created automatically when you create the DSV. After the DSV exists, you can create additional diagrams, remove them, or hide specific objects to create a more manageable representation of the DSV.

To create a new diagram, right-click anywhere in the **Diagram Organizer** pane, click **New Diagram**.

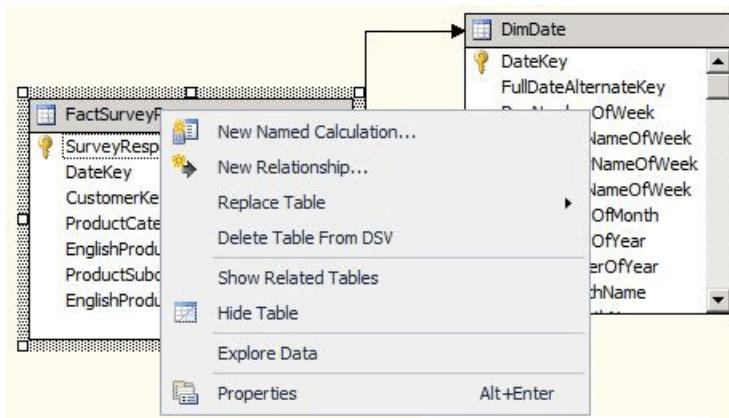

When you initially define a data source view (DSV) in an Analysis Services project, all tables and views added to the data source view are added to the <All Tables> diagram. This diagram appears in the Diagram Organizer pane in Data Source View Designer, the tables in this diagram (and their columns and relationships) are listed in the Tables pane, and the tables in this diagram (and their columns and relationships) are displayed graphically in the schema pane. However, as you add tables, views and named queries to the <All Tables> diagram, the sheer number of objects in this diagram makes it difficult to visualize relationships-particularly as multiple fact tables are added to the diagram, and dimension tables relate to multiple fact tables.

To reduce the visual clutter when you only want to view a subset of the tables in the data source view, you can define sub-diagrams (simply called diagrams) consisting of selected subsets of the tables, views, and named queries in the data source view. You can use diagrams to group items in the data source view according to business or solution needs.

You can group related tables and named queries in separate diagrams for business purposes, and to make it easier to understand a data source view that contains many tables, views, and named queries. The same table or named query can be included in multiple diagrams except for the <All Tables> diagram. In the <All Tables> diagram, all objects that are contained in the data source view are shown exactly once.

Edit or Delete a Diagram

When working with a diagram, pay close attention to the commands used for adding and removing objects. For example, deleting an object from a diagram will delete it from the DSV. If you only want to delete it from the diagram, use **Hide Table** instead.

Although you can hide objects individually, bringing them back using the Show Related Tables command returns all related objects to the diagram. To control which objects are returned to the workspace, drag them from the Tables pane instead.

Find Tables in a Diagram

If your schema is large, scrolling to a particular table in the **Diagram** pane may be difficult. However, the following tools make it easy to find a table in a diagram.

- Scroll the list of tables in the **Tables** pane.

To include a table in the currently displayed diagram, drag the table from the **Tables** pane to the diagram pane.

To center the display on a table that is already included in the diagram, select the table in the **Tables** pane.

- Table locator in **Diagram** pane-The table locator is a 4-way arrow icon located at the intersection of the vertical and horizontal scroll bars in the lower right corner of the **Diagram** pane. It opens a thumbnail representation of the current diagram in the Diagram pane. You can use this thumbnail to change the view in the Diagram pane to any location on the diagram.
- Use the **Find Table** dialog box- Right-click on open area in the Diagram pane and click **Find Table**. Or, click the **Find Table** command on the toolbar or the **Data Source View** menu.

You can type strings and wildcard characters in the Filter box to view subsets of the tables in the diagram.

Arrange Objects in a Diagram

Although Data Source View Designer can define multiple diagrams to make a DSV more understandable, diagrams that contain dozens of tables can be hard to read and manually rearranging table layouts is a tedious process. The Data Source View Designer can automatically rearrange tables in the current diagram using either a rectangular or diagonal layout based on the relationships between tables in the current diagram.

- In a rectangular layout, the relationship lines are drawn between tables instead of between columns. Relationship lines are drawn horizontally and vertically between tables.
- In a diagonal layout, relationship lines are drawn as directly as possible between related columns in tables. A relationship to multiple columns attaches to the first related column in the table. If the columns in a table are not visible, the lines are drawn to the top of the table.

Preserve object arrangement

After manually arranging tables the way you want, adding more tables to the diagram can result in a diagram refresh that removes any recent modifications you made to the object layout.

This behavior is more likely to occur when you add a table, causing the Diagram Organizer to move other tables in order to accommodate the new one. It then redraws the diagram to ensure all tables and connection lines represented correctly. At this point, any manual adjustments to the placement of specific objects might be lost.

To avoid this problem, add all the tables first, before making any final adjustments. Objects should now retain their position in the diagram when you open it again later.

Refresh the Schema in a Data Source View (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After defining a data source view (DSV) in an Analysis Services project or database, the schema in an underlying data source may change. These changes are not automatically detected or updated in a development project. Moreover, if you deployed the project to a server, you will now encounter processing errors if Analysis Services can no longer connect to the external data source.

To update the DSV so that it matches the external data source, you can refresh the DSV in Business Intelligence Development Studio (BIDS). Refreshing the DSV detects changes to the external data sources upon which the DSV is based, and builds a change list that enumerates the additions or deletions in the external data source. You can then apply the set of changes to the DSV that will realign it to the underlying data source. Note that additional work is often required to further update the cubes and dimensions in the project that use the DSV.

This topic includes the following sections:

[Changes Supported in Refresh](#)

[Refresh a DSV in SQL Server Data Tools](#)

Changes Supported in Refresh

DSV Refresh can include any of the following actions:

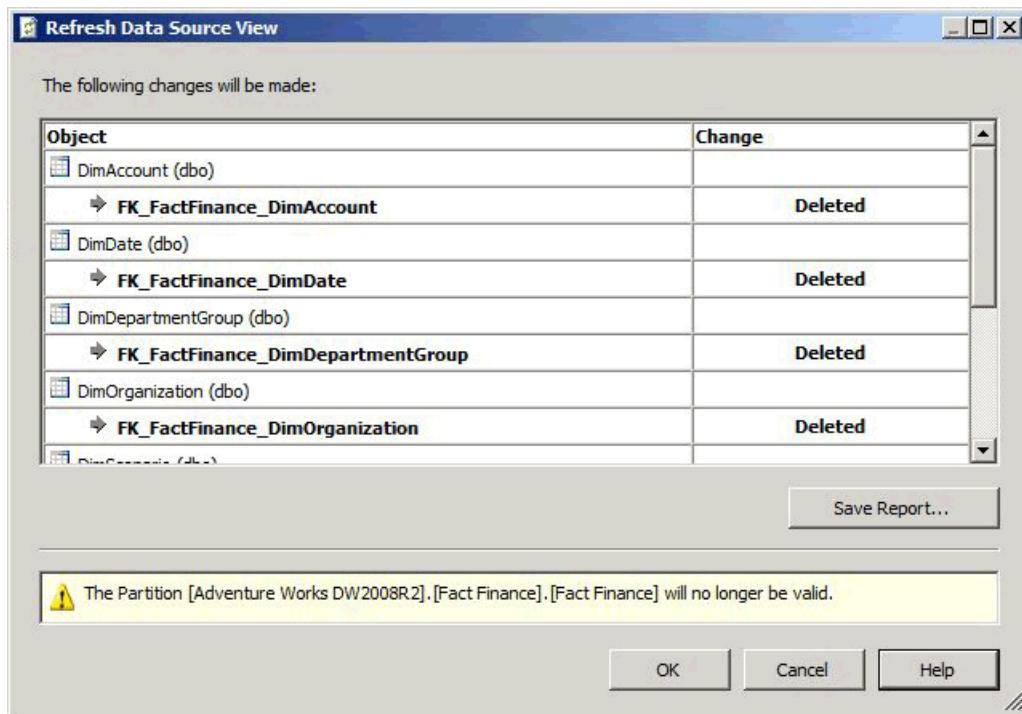

- Deletion of tables, columns, and relationships
- Addition of columns and relationships, as applied to tables that are already included in the DSV
- Addition of new unique constraints. If a logical primary key exists for a table in the DSV and a physical key is added to the table in the data source, the logical key is removed and replaced by the physical key.

Refresh never adds new tables to a DSV. If you want to add a new table, you must add it manually. For more information, see [Adding or Removing Tables or Views in a Data Source View \(Analysis Services\)](#).

Refresh a DSV in SQL Server Data Tools

To refresh a DSV, double-click the DSV from Solution Explorer in Visual Studio with Analysis Services projects. This launches the DSV designer. Then click the Refresh Data Source View button in the designer or choose **Refresh** from the Data Source View menu.

During refresh, Analysis Services queries all underlying relational data sources to determine whether there have been changes in tables/views which are included in the DSV. If connections can be established to all underlying data sources and there have been any changes, you will see them in the **Refresh Data Source View** dialog box.

The dialog box lists tables, columns, constraints, and relationships that will be deleted or added in the DSV. The report also lists any named query or calculation that cannot be successfully prepared. The affected objects are listed in a tree view with columns and relationships nested under tables and the type of change (deletion or addition) indicated for each object. The standard data source view object icons indicate the type of object affected.

Refresh is based completely on the names of the underlying objects. Therefore, if an underlying object is renamed in the data source, Data Source View Designer treats the renamed object as two separate operations-a deletion and an addition. In this case, you may have to manually add the renamed object back to the data source view. You may also have to re-create relationships or logical primary keys.

IMPORTANT

If you are aware that a table has been renamed in a data source, you may want to use the **Replace Table** command to replace the table with the renamed table before you refresh the data source view. For more information, see [Replace a Table or a Named Query in a Data Source View \(Analysis Services\)](#).

After you examine the report, you can either accept the changes or cancel the update to reject any changes. All changes must be accepted or rejected together. You cannot choose individual items in the list. You can also save a report of the changes.

[Data Source Views in Multidimensional Models](#)

Replace a Table or a Named Query in a Data Source View (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Data Source View Designer, you can replace a table, view, or named query in a data source view (DSV) with a different table or view from the same or a different data source, or with a named query defined in the DSV. When you replace a table, all other objects in an Analysis Services database or project that have references to the table continue to reference the table because the object ID for the table in the DSV does not change. Any relationships that are still relevant (based on name and column-type matching) are retained. In contrast, if you delete and then add a table, references and relationships are lost and must be recreated.

To replace a table with another table, you must have an active connection to the source data in Data Source View Designer in project mode.

You most frequently replace a table in the data source view with another table in the data source. However, you can also replace a named query with a table. For example, you previously replaced a table with a named query, and now want to revert to a table.

IMPORTANT

If you rename a table in a data source, follow the steps for replacing a table and specify the renamed table as the source of the corresponding table in the DSV before you refresh a DSV. Completing the replacement and renaming process preserves the table, the table's references, and the table's relationships in the DSV. Otherwise, when you refresh the DSV, a renamed table in data source is interpreted as being deleted. For more information, see [Refresh the Schema in a Data Source View \(Analysis Services\)](#).

Replace a table with a named query

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you want to replace a table or a named query.
2. In Solution Explorer, expand the **Data Source Views** folder, and then double-click the data source view.
3. Open the **Create Named Query** dialog box. In either **Tables** or **Diagram** pane, right-click the table that you wish to replace, point to **Replace Table** and then click **With New Named Query**.
4. In the **Create Named Query** dialog box, define the named query and then click **OK**.
5. Save the modified data source view.

Replace a table or named query with a table

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you want to replace a table or a named query.
2. In Solution Explorer, expand the **Data Source Views** folder, and then double-click the data source view.
3. Open the **Replace Table with Other Table** dialog box. In either **Tables** or **Diagram** pane, right-click the table or named query that you wish to replace, point to **Replace Table** and then click **With Other Table**.

4. In the **Replace Table with Other Table** dialog box:
 - a. In the **DataSource** drop-down list box, select the desired data source
 - b. Select the table with which you wish to replace the table or named query
5. Click **OK**.
6. Save the modified data source view.

[Data Source Views in Multidimensional Models](#)

Define Logical Relationships in a Data Source View (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Data Source View Wizard and Data Source View Designer automatically define relationships between tables added to a data source view (DSV) based on underlying database relationships or name matching criteria you specify.

In cases where you are working with data from multiple data sources, you may need to manually define logical relationships in the DSV to supplement those relationships that are defined automatically. Relationships are required in Analysis Services to identify fact and dimension tables, to construct queries for retrieving data and metadata from underlying data sources, and to take advantage of advanced business intelligence features.

You can define the following types of relationships in Data Source View Designer:

- A relationship from one table to another table in the same data source.
- A relationship from one table to itself, as in a parent-child relationship.
- A relationship from one table in a data source to another table in a different data source.

NOTE

The relationships defined in a DSV are logical and may not reflect the actual relationships defined in the underlying data source. You can create relationships in Data Source View Designer that do not exist in the underlying data source, and remove relationships created by Data Source View Designer from existing foreign key relationships in the underlying data source.

Relationships are directed. For every value in the source column, there is a corresponding value in the destination column. In a data source view diagram, such as the diagrams displayed in the **Diagram** pane, an arrow on the line between two tables indicates the direction of the relationship.

This topic includes the following sections:

[To add a relationship between tables, named queries, or views](#)

[To view or modify a relationship in the Diagram pane](#)

[To view or modify a relationship in the Tables pane](#)

To add a relationship between tables, named queries, or views

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you wish to add a logical relationship.
2. In Solution Explorer, expand the **Data Source Views** folder, then double-click the data source view to open it in **Data Source View Designer**.
3. Right-click the table, named query or view to which you want to add a relationship in either the **Tables** pane and then click **New Relationship**.

NOTE

To locate a table, view or named query, you can use the **Find Table** option by either clicking the **Data Source View** menu or right-clicking in an open area of the **Tables** or **Diagram** panes.

4. In the **Specify Relationship** dialog box, do the following:

- a. Select the appropriate table, named query, or view in the **Source (foreign key) table** list.
- b. Select the appropriate table, named query, or view in the **Destination (primary key) table** lists.
- c. Select columns from the **Source Columns** and **Destination Columns** lists to create a relationship between the two tables.

If Visual Studio with Analysis Services projects detects, by sampling the data in the underlying table, view, or named query, that you have defined the relationship in the wrong direction (from the primary key to the foreign key rather than from the foreign key to the primary key), you will be prompted to reverse the order. To quickly reverse the order, click **Reverse**.

If Visual Studio with Analysis Services projects detects that a relationship already exists for the columns you have selected, you will be prompted. You cannot define duplicate relationships.

- d. Optionally, in the **Description** box, type a description for the relationship.

To view or modify a relationship in the Diagram pane

- In the **Diagram** pane in **Data Source View Designer**, right-click the relationship that you want to view and click **Edit Relationship** (or simply double-click the relationship arrow). Use the **Edit Relationship** dialog box to modify the relationship.

To view or modify a relationship in the Tables pane

1. In the **Tables** pane in **Data Source View Designer**, locate and then expand the table, view or named query containing the relationship that you wish to view or modify.
2. Expand the **Relationships** folder. The relationships between the selected table, view or named query and other tables, views and named queries appear with the relationship column listed.
3. Right-click the relationship you want to modify, and then click **Edit Relationship**.

[Data Source Views in Multidimensional Models](#)

Define Logical Primary Keys in a Data Source View (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Data Source View Wizard and Data Source View Designer automatically define a primary key for a table that is added to a data source view based on underlying database table.

Occasionally, you may need to manually define a primary key in the data source view. For example, for performance or design reasons, tables in a data source may not have explicitly defined primary key columns. Named queries and views may also omit the primary key column for a table. If a table, view, or named query does not have a physical primary key defined, you can manually define a logical primary key on the table, view or named query in Data Source View Designer.

Set a Logical Primary Key

Primary keys are required in Analysis Services to uniquely identify records in a table, identify key columns in dimension tables and to support relationships between tables, views and named queries. These relationships are used to construct queries for retrieving data and metadata from underlying data sources, and to take advantage of advanced business intelligence features.

Any column can be used for the logical primary key, including a named calculation. When you create a logical primary key, a unique constraint is created in the data source view and marked as a primary key constraint. Any other existing logical primary key specified in the selected table is deleted.

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you wish to set a logical primary key.
2. In Solution Explorer, expand the **Data Source Views** folder, then double-click the data source view.

To locate a table or view, you can use the **Find Table** option by either clicking the **Data Source View** menu or right-clicking in an open area of the **Tables** or **Diagram** panes.

3. In either the **Tables** or the **Diagram** pane, right-click the column or columns that you want to use to define a logical primary key, and then click **Set Logical Primary Key**.

The option to set a logical primary key is available only for tables that do not have a primary key.

Notice that after you set the key, a key icon now identifies the primary key columns.

[Data Source Views in Multidimensional Models](#)

[Define Named Calculations in a Data Source View \(Analysis Services\)](#)

Define Named Calculations in a Data Source View (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A named calculation is a SQL expression represented as a calculated column. This expression appears and behaves as a column in the table. A named calculation lets you extend the relational schema of existing tables or views in a data source view without modifying the tables or views in the underlying data source. Consider the following examples:

- Create a single named calculation that is derived from multiple columns in a fact table (for example, creating Tax Amount by multiplying a tax rate by a sales price).
- Construct a user friendly name for a dimension member.
- As a query performance enhancement, create a named calculation in the DSV instead of creating a calculated member in a cube. Named calculations are calculated during processing whereas calculated members are calculated at query time.

Creating Named Calculations

NOTE

You cannot add a named calculation to a named query, nor can you base a named query on a table that contains a named calculation.

When you create a named calculation, you specify a name, the SQL expression, and, optionally, a description of the calculation. The SQL expression can refer to other tables in the data source view. After the named calculation is defined, the expression in a named calculation is sent to the provider for the data source and validated as the following SQL statement in which `<Expression>` contains the expression that defines the named calculation.

```
SELECT  
    <Table Name in Data Source>.*,  
    <Expression> AS <Column Name>  
FROM  
    <Table Name in Data Source> AS <Table Name in Data Source View>
```

The data type of the column is determined by the data type of the scalar value returned by the expression. If the provider does not find any errors in the expression, the column is added to the table.

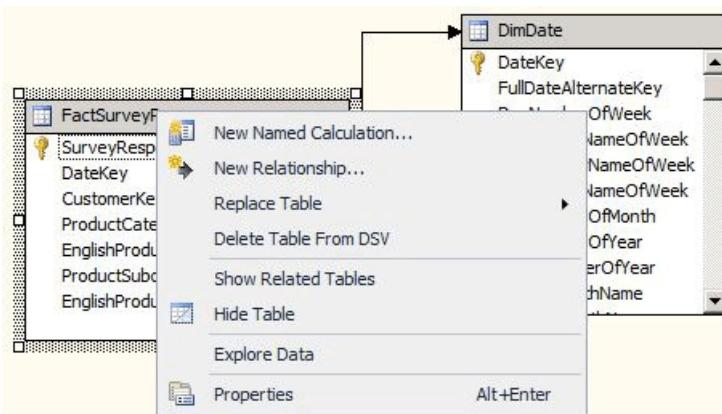

Columns referenced in the expression should not be qualified or should be qualified by the table name only. For example, to refer to the SaleAmount column in a table, `SaleAmount` or `Sales.SaleAmount` is valid, but `dbo.Sales.SaleAmount` generates an error.

The expression is not automatically enclosed between parentheses. Therefore, if an expression, such as a SELECT statement, requires parentheses, you must type the parentheses in the **Expression** box. For example, the following expression is valid only if you type the parentheses.

```
(SELECT Description FROM Categories WHERE Categories.CategoryID = CategoryID)
```

Add or Edit a Named Calculation

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you wish to define a named calculation.
2. In Solution Explorer, expand the **Data Source Views** folder, then double-click the data source view.
3. Right-click the table in which you wish to define the named calculation in either the **Tables** or the **Diagram** pane, and then click **New Named Calculation**. Be sure to right-click on the table name, and not on an attribute. The menu should look like the following:

NOTE

To locate a table or view, you can use the **Find Table** option by either clicking the **Data Source View** menu or right-clicking in an open area of the **Tables** or **Diagram** panes.

4. In the **Create Named Calculations** dialog box, do the following:
 - In the **Column name** text box, type the name of the new column.
 - In the **Description** text box type a description for the new column.
 - In the **Expression** text box, type the expression that yields the content of the new column in the SQL dialect appropriate for the data provider.
5. Click **OK**.

The named calculation column appears as the last column in the data source view table. A calculator symbol indicates that the column contains a named calculation.

Delete a Named Calculation

When you attempt to delete a named calculation, you are prompted with a list of the objects defined in the project or database that will be invalidated by the deletion. Review the list carefully before deleting the calculation.

See Also

[Define Named Queries in a Data Source View \(Analysis Services\)](#)

Define Named Queries in a Data Source View (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A named query is a SQL expression represented as a table. In a named query, you can specify an SQL expression to select rows and columns returned from one or more tables in one or more data sources. A named query is like any other table in a data source view (DSV) with rows and relationships, except that the named query is based on an expression.

A named query lets you extend the relational schema of existing tables in DSV without modifying the underlying data source. For example, a series of named queries can be used to split up a complex dimension table into smaller, simpler dimension tables for use in database dimensions. A named query can also be used to join multiple database tables from one or more data sources into a single data source view table.

Creating a Named Query

NOTE

You cannot add a named calculation to a named query, nor can you base a named query on a table that contains a named calculation.

When you create a named query, you specify a name, the SQL query returning the columns and data for the table, and optionally, a description of the named query. The SQL expression can refer to other tables in the data source view. After the named query is defined, the SQL query in a named query is sent to the provider for the data source and validated as a whole. If the provider does not find any errors in the SQL query, the column is added to the table.

Tables and columns referenced in the SQL query should not be qualified or should be qualified by the table name only. For example, to refer to the SaleAmount column in a table, `SaleAmount` or `Sales.SaleAmount` is valid, but `dbo.Sales.SaleAmount` generates an error.

Note When defining a named query that queries a SQL Server 2000 (8.x) or SQL Server 7.0 data source, a named query that contains a correlated subquery and a GROUP BY clause will fail. For more information, see [Internal Error with SELECT Statement Containing Correlated Subquery and GROUP BY](#) in the Microsoft Knowledge Base.

Add or Edit a Named Query

1. In Visual Studio with Analysis Services projects, open the project or connect to the database that contains the data source view in which you want to add a named query.
2. In Solution Explorer, expand the **Data Source Views** folder, then double-click the data source view.
3. In the **Tables** or **Diagram** pane, right-click an open area and then click **New Named Query**.
4. In the **Create Named Query** dialog box, do the following:
 - a. In the **Name** text box, type a query name.

- b. Optionally, in the **Description** text box, type a description for the query.
- c. In the **Data Source** list box, select the data source against which the named query will execute.
- d. Type the query in the bottom pane, or use the graphical query building tools to create a query.

NOTE

The query-building user interface (UI) depends on the data source. Instead of getting a graphical UI, you can get a generic UI, which is text-based. You can accomplish the same things with these different UIs, but you must do so in different ways. For more information, see [Create or Edit Named Query Dialog Box \(Analysis Services - Multidimensional Data\)](#).

5. Click **OK**. An icon showing two overlapping tables appears in the table header to indicate that the table has been replaced by a named query.

[Define Named Calculations in a Data Source View \(Analysis Services\)](#)

Delete a Data Source View (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

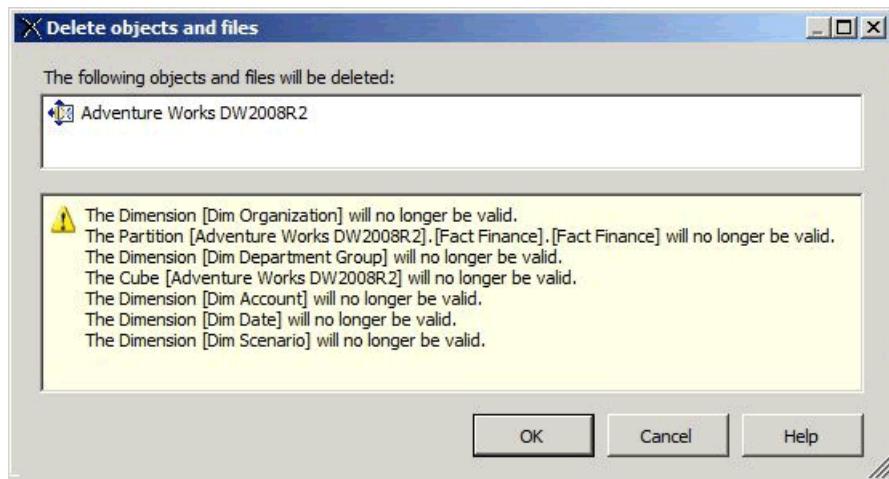

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

If you are no longer using a data source view (DSV) in an OLAP project, you can delete it from the project in Visual Studio with Analysis Services projects.

Deleting a DSV is permanent. You cannot restore a deleted DSV to a Analysis Services project or database.

DSVs that other objects depend on cannot be deleted from an Analysis Services database opened by Visual Studio with Analysis Services projects in online mode. To delete a DSV from a project that is connected o a database running on a server, you must first delete all objects in the Analysis Services database that depend on that DSV before deleting the DSV itself.

Deleting a DSV will invalidate other Analysis Services objects that depend on it, so before you delete the DSV, you will see the list of objects that will become invalid once the DSV is removed. Review this list carefully to be sure that it does not include objects you still expect to use.

[Data Source Views in Multidimensional Models](#)

[Change Properties in a Data Source View \(Analysis Services\)](#)

Change Properties in a Data Source View (Analysis Services)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After defining a data source view using the Data Source View Wizard and adding tables, views, named calculations, and named queries to the data source view, you may want to change properties related to:

- Data source view matching criteria
- Advanced data source view options
- Object names
- Object metadata

You can also view object metadata retrieved from the data source that you cannot modify.

Viewing or Changing Data Source View Properties

Data source view properties, other than a description of the data source view, are set by the Data Source View Wizard when you initially define the data source view. The following table lists and describes the properties of a data source view.

NOTE

The Properties pane shows properties for the .dsv file as well as the DSV object. To view the properties of the object, double-click it in Solution Explorer. The Properties will update to reflect the properties you see in the following table.

| PROPERTY | DESCRIPTION |
|----------------------|---|
| Data Source | Specifies the data source within the data source view whose properties you are viewing |
| Description | Specifies a description of the data source view |
| Name | Specifies the name of the data source view that appears in Solution Explorer or the Analysis Services database. You can change the data source view name here or in Solution Explorer. |
| NameMatchingCriteria | The name matching criteria for the data source. The default is (none) if primary key - foreign key relationships were detected by the Data Source View Wizard. Regardless of whether this property was set by the Data Source View Wizard, you can specify a value here. If database relationships exist and you specify name matching criteria, both will be used to infer relationships between existing tables and newly added tables. |

| PROPERTY | DESCRIPTION |
|-----------------------|--|
| RetrieveRelationships | Specifies whether relationships are retrieved from the database. Default is True. |
| SchemaRestriction | Specifies the restrictions, if any, on the schemas retrieved from a data source. By default, no schema restrictions exist. |

Viewing or Changing DataTable Properties

DataTable properties are the properties of tables, views, and named queries in a data source view. These properties are set when any of these objects is added to the data source view. The following table lists and describes the properties of **DataTable** objects in a data source view.

| PROPERTY | DESCRIPTION |
|------------------------------|---|
| AllowChangesDuringGeneration | Specifies whether the Schema Generation Wizard has permission to overwrite a data source view table during regeneration. This property will only exist on tables initially generated by the Schema Generation Wizard. For more information, see Understanding Incremental Generation . |
| DataSource | Specifies the data source for the object. You cannot edit this property. |
| Description | Specifies the description for the table, view or named query. If the underlying database table or view had a description stored as an extended property, this value appears. You can edit this property. |
| FriendlyName | Specifies a name for the table or view that is easier for users to understand or more relevant to the subject area. By default, the FriendlyName property of a table or view is the same as the Name property of the table or view. The FriendlyName property is used by OLAP and data mining objects when defining object names based on tables or views. You can edit this property. |
| Name | Specifies the name of the underlying table or view, or the name of the named query. The Name property is used by OLAP and data mining objects when defining object names based on named queries. This property is only editable for named queries. |
| QueryDefinition | Specifies the named query definition. This property is only applicable to named queries and is not directly editable. To edit this property, you edit the named query itself. |
| Schema | Specify the database schema applicable to the table, view or named query. This property is not editable. |
| TableType | Specifies the type of table for the table, view or named query. This property is not editable. |

Viewing or Changing DataColumn Properties

DataColumn properties are the properties of columns in tables, views, and named queries in a data source view. These properties are set when any of these objects is added to the data source view, either from the underlying table or view, from a named query, or as defined by a named calculation. The following table lists and describes the properties of **DataColumn** objects in a data source view.

| PROPERTY | DESCRIPTION |
|--------------|---|
| AllowNull | Specifies the nullability property of the column based on the column in the underlying table, value or named query. This property is not editable. |
| DataType | Specifies the data type of the column based on the column in the underlying table, value or named query. This property is not directly editable. However, if you need to change the data type of a column from a table or view, replace the table with a named query that converts the column to the desired data type. |
| DateTimeMode | Specifies the date serialization format for DateTime columns. The default value is UnspecifiedLocal . This property is editable. |
| Description | Specifies the description for the column. If the underlying database column had a description stored as an extended property, this value appears. You can edit this property. |
| FriendlyName | Specifies the name for a column from a table or view that is easier for users to understand or more relevant to the subject area. By default, the FriendlyName property of a column from a table or view is the same as the Name property of the column. The FriendlyName property is used by OLAP and data mining objects when defining attributes based on columns from tables or views. You can edit this property. |
| Length | Specifies the maximum length of the column, based on the data in the column in the underlying table or view. |
| Name | Specifies the name of the underlying column, or the name of the named calculation. The Name property is used by OLAP and data mining objects when defining attributes based on named calculations. This property is only editable for named calculations. |

Schema Generation Wizard (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Visual Studio with Analysis Services projects supports two methods of working with relational schemas when defining OLAP objects within an Analysis Services project or database. Generally, you will define OLAP objects based on a logical data model constructed in a data source view within an Analysis Services project or database. This data source view is defined based on schema elements from one or more relational data sources, as customized in the data source view.

Alternatively, you can define OLAP objects first, and then generate a data source view, a data source, and the underlying relational database schema that supports these OLAP objects. This relational database is referred to as the subject area database.

This approach is sometimes called top-down design and is frequently used for prototyping and analysis modeling. When you use this approach, you use the Schema Generation Wizard to create the underlying data source view and data source objects based on the OLAP objects defined in an Analysis Services project or database.

This is an iterative approach. You will most likely rerun the wizard multiple times as you change the design of the dimensions and cubes. Each time you run the wizard, it incorporates the changes into the underlying objects and, as much as is possible, preserves the data contained in the underlying databases.

The schema that is generated is a SQL Server relational database engine schema. The wizard does not generate schemas for other relational database products.

The data that is populated in the subject area database is added separately, using whatever tools and techniques you use to populate a SQL Server relational database. In most cases, the data is preserved when you rerun the wizard, but there are exceptions. For example, some data must be dropped if you delete a dimension or an attribute that contains data. If the Schema Generation Wizard must drop some data because of a schema change, you receive a warning before the data is dropped and can then cancel the regeneration.

As a general rule, any change that you make to an object that was originally generated by the Schema Generation Wizard is overwritten when the Schema Generation Wizard subsequently regenerates that object. The primary exception to this rule is when you add columns to a table that the Schema Generation Wizard generated. In this case, the Schema Generation Wizard preserves the columns that you added to the table, as well as the data in these columns.

In this section

The following table lists additional topics that explain how to work with the Schema Generation Wizard.

| TOPIC | DESCRIPTION |
|--|---|
| Use the Schema Generation Wizard (Analysis Services) | Describes how to generate the schema for the subject area and staging area databases. |
| Understanding the Database Schemas | Describes the schema that is generated for the subject area and staging area databases. |
| Understanding Incremental Generation | Describes the incremental generation capabilities of the Schema Generation Wizard. |

Use the Schema Generation Wizard (Analysis Services)

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Schema Generation Wizard requires a limited amount of information during the generation phase. Most of the information that the Schema Generation Wizard requires for generating relational schemas is extracted from the Analysis Services cubes and dimensions that you already created in the project. Additionally, you can customize how the subject area database schema is generated and how objects in the schema are named.

Start the Wizard

You can open the Schema Generation Wizard from Visual Studio with Analysis Services projects in several different ways:

- Right-click the Analysis Services project object and then click **Generate Relational Schema** from the context menu.
- Click the Analysis Services project object, and then click **Generate Relational Schema** from the **Database** menu.
- Start the wizard from within the Dimension Wizard by clicking the **Generate Schema Now** check box on the last page of the wizard.

Step 1: Specify Targets

You must specify the data source view (DSV) in which you want the Schema Generation Wizard to generate the schema for the subject area database. Although you can select an existing DSV, typically you create a new one based on a data source. You can create the data source based on an existing or a new connection, or based on another object. The Schema Generation Wizard generates the schema for the subject area database in the database referenced by the data source, as well as the data source view. The Schema Generation Wizard does not create the subject area database itself; instead, the wizard creates the relational schema to support the cubes and dimensions in an existing database that you specify.

When the Schema Generation Wizard generates the underlying objects, it binds the Analysis Services dimensions and cubes to the generated tables and columns by using data source view-style bindings.

NOTE

To unbind Analysis Services dimensions and cubes from previously generated objects, delete the data source view to which the Analysis Services cubes and dimensions are bound, and then define a new data source view for the cubes and dimensions by using the Schema Generation Wizard.

Step 3: Specify Schema Options for the Subject Area Database

The Schema Generation Wizard provides a number of options for defining the schema that is generated for the subject area database. You can specify these options on the **Subject Area Database Schema Options** page of the wizard.

Specifying the Schema Owner

You can specify the owner of the schema by setting the value of **Owning schema** to a valid string. The default owner of the schema is the Analysis Services project, but you can specify any desired schema owner.

Specifying Primary Keys, Indexes, and Constraints

The Schema Generation Wizard by default creates a primary key constraint in each dimension table in the subject area database. The primary key corresponds to the attribute that is designated as the key attribute in the corresponding Analysis Services dimension. This constraint improves processing performance in most environments, with minimal cost. Logical primary keys are always created in the data source view, even if you choose not to create the primary key in the subject area database. To define primary key constraints on dimension tables, select **Create primary keys on dimension tables**.

The wizard by default also creates indexes on the foreign key columns in each fact table. These indexes improve processing performance in most environments. Performance is typically improved because the processing queries that Analysis Services generates to retrieve new data from the subject area database typically include a significant number of join statements between the fact table and the dimension tables. To define indexes on the foreign key columns in each fact table, select **Create indexes**.

Finally, the wizard by default enforces referential integrity between the fact table and each of the dimension tables. If you choose not to enforce referential integrity, the Schema Generation Wizard still creates these relationships in the database and the data source view. To enforce referential integrity, select **Enforce referential integrity**.

Preserving Data for Incremental Generation

The Schema Generation Wizard by default attempts to preserve data when the database schema is regenerated. If the Schema Generation Wizard has to delete any rows because of a schema change, you receive a warning before the rows are deleted. For example, rows may have to be deleted to solve referential integrity issues because you dropped a dimension or because a data type changed when you changed a dimension attribute. To preserve data when the database schema is regenerated, select **Preserve data on regeneration**.

Step 4: Specify Naming Conventions

You can define the naming conventions that the Schema Generation Wizard uses when generating certain objects in the subject area database on the **Specify Naming Conventions** page of the wizard. For more information about the options available on the **Specify Naming Conventions** page, see [Specify Naming Conventions \(Schema Generation Wizard\) \(Analysis Services - Multidimensional Data\)](#).

Understanding the Database Schemas

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

The Schema Generation Wizard generates a denormalized relational schema for the subject area database based on the dimensions and measure groups in Analysis Services. The wizard generates a relational table for each dimension to store dimension data, which is called a dimension table, and a relational table for each measure group to store fact data, which is called a fact table. The wizard ignores linked dimensions, linked measure groups, and server time dimensions when it generates these relational tables.

Validation

Before it begins to generate the underlying relational schema, the Schema Generation Wizard validates the Analysis Services cubes and dimensions. If the wizard detects errors, it stops and reports the errors to the Task List window in Visual Studio with Analysis Services projects. Examples of errors that prevent generation include the following:

- Dimensions that have more than one key attribute.
- Parent attributes that have different data types than the key attributes.
- Measure groups that do not have measures.
- Degenerate dimensions or measures that are improperly configured.
- Surrogate keys that are improperly configured, such as multiple attributes using the **ScdOriginalID** attribute type or an attribute using the **ScdOriginalID** that is not bound to a column using the integer data type.

Dimension Tables

For each dimension, the Schema Generation Wizard generates a dimension table to be included in the subject area database. The structure of the dimension table depends on the choices made while designing the dimension on which it is based.

Columns

The wizard generates one column for the bindings associated to each attribute in the dimension on which the dimension table is based, such as the bindings for the **KeyColumns**, **NameColumn**, **ValueColumn**, **CustomRollupColumn**, **CustomRollupPropertiesColumn**, and **UnaryOperatorColumn** properties of each attribute.

Relationships

The wizard generates a relationship between the column for each parent attribute and the primary key of the dimension table.

The wizard also generates a relationship to the primary key in each additional dimension table defined as a referenced dimension in the cube, if applicable.

Constraints

The wizard generates a primary key constraint, by default, for each dimension table based on the key attribute of the dimension. If the primary key constraint is generated, a separate name column is generated by default. A logical primary key is created in the data source view even if you decide not to create the primary key in the

database.

NOTE

An error occurs if more than one key attribute is specified in the dimension on which the dimension table is based.

Translations

The wizard generates a separate table to hold the translated values for any attribute that requires a translation column. The wizard also creates a separate column for each of the required languages.

Fact Tables

For each measure group in a cube, the Schema Generation Wizard generates a fact table to be included in the subject area database. The structure of the fact table depends on the choices made while designing the measure group on which it is based, and the relationships established between the measure group and any included dimensions.

Columns

The wizard generates one column for each measure, except for measures that use the **Count** aggregation function. Such measures do not require a corresponding column in the fact table.

The wizard also generates one column for each granularity attribute column of each regular dimension relationship on the measure group, and one or more columns for the bindings associated to each attribute of a dimension that has a fact dimension relationship to the measure group on which this table is based, if applicable.

Relationships

The wizard generates one relationship for each regular dimension relationship from the fact table to the dimension table's granularity attribute. If the granularity is based on the key attribute of the dimension table, the relationship is created in the database and in the data source view. If the granularity is based on another attribute, the relationship is created only in the data source view.

If you chose to generate indexes in the wizard, a non-clustered index is generated for each of these relationship columns.

Constraints

Primary keys are not generated on fact tables.

If you chose to enforce referential integrity, referential integrity constraints are generated between dimension tables and fact tables where applicable.

Translations

The wizard generates a separate table to hold the translated values for any property in the measure group that requires a translation column. The wizard also creates a separate column for each of the required languages.

Data Type Conversion and Default Lengths

Schema Generation Wizard ignores data types in all cases except for columns that use the SQL Server **wchar** data type. The **wchar** data size translates directly to the **nvarchar** data type. However, if the specified length of a column using the **wchar** size is larger than 4000 bytes, the Schema Generation Wizard generates an error.

If a data item, such as the binding for an attribute, has no specified length, the default length listed in the following table is used for the column.

| DATA ITEM | DEFAULT LENGTH (BYTES) |
|------------------------------|------------------------|
| KeyColumn | 50 |
| NameColumn | 50 |
| CustomRollupColumn | 3000 |
| CustomRollupPropertiesColumn | 500 |
| UnaryOperatorColumn | 1 |

[Understanding Incremental Generation](#)

[Manage Changes to Data Source Views and Data Sources](#)

Understanding Incremental Generation

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Following the initial schema generation, you can change cube and dimension definitions by using Visual Studio with Analysis Services projects, and then rerun the Schema Generation Wizard. The wizard updates the schema in the subject area database and in the associated data source view to reflect the changes, and retaining the data that currently exists in the tables to be regenerated, to the extent possible. If you changed the tables after the initial generation, the Schema Generation Wizard preserves those changes when possible by using the following rules:

- If a table was previously generated by the wizard, the table is overwritten. You can prevent a table that was generated by the wizard from being overwritten by changing the **AllowChangesDuringGeneration** property for the table in the data source view to **false**. When you take control of a table, the table is treated like any other user-defined table and is not affected during regeneration. After you remove a table from generation, you can later change the **AllowChangesDuringGeneration** property for the table in the data source view to **true** and reopen the table for changes by the wizard. For more information, see [Change Properties in a Data Source View \(Analysis Services\)](#).
- If a table was added to the data source view or to the underlying database by something other than the wizard, the table is not overwritten.

When the Schema Generation Wizard regenerates tables that were previously generated in the subject area database, you can choose to have the wizard preserve existing data in those tables.

Supporting Data Preservation

As a general rule, the Schema Generation Wizard preserves data that is stored in the tables that it generated. In addition, if you add columns to tables that the wizard generated, the wizard preserves that data as well. You can use this capability to add or modify your dimensions and cubes and then regenerate the underlying objects without having to reload the data stored in the underlying tables.

NOTE

If you are loading data from delimited text files, you can also choose whether the Schema Generation Wizard overwrites these files and the data contained in them during regeneration. Text files are either overwritten completely or not at all. The Schema Generation Wizard does not partially overwrite these files. By default, these files are not overwritten.

Partial Preservation

The Schema Generation Wizard cannot preserve existing data under some circumstances. The following table provides examples of situations in which the wizard cannot preserve all the existing data in the underlying tables during regeneration.

| TYPE OF DATA CHANGE | TREATMENT |
|-------------------------------|---|
| Incompatible data type change | The Schema Generation Wizard uses standard SQL Server data type conversions, whenever possible, to convert existing data from one data type to another. However, when you change an attribute's data type to a type that is incompatible with the existing data, the wizard drops the data for the affected column. |

| TYPE OF DATA CHANGE | TREATMENT |
|--------------------------------|--|
| Referential integrity errors | If you change a dimension or cube that contains data and the change causes a referential integrity error during regeneration, the Schema Generation Wizard drops all data in the foreign key table. The data that is dropped is not limited to the column that caused the foreign key constraint violation or to the rows that contain the referential integrity errors. For example, if you change the dimension key to an attribute that has non-unique or null data, all existing data in the foreign key table is dropped. Furthermore, dropping all the data in one table can have a cascading effect and can cause other referential integrity violations. |
| Deleted attribute or dimension | If you delete an attribute from a dimension, the Schema Generation Wizard deletes the column that is mapped to the deleted attribute. If you delete a dimension, the wizard deletes the table that is mapped to the deleted dimension. In these cases, the wizard drops the data that is contained in the deleted column or table. |

The Schema Generation Wizard issues a warning before it drops any data so that you can cancel the wizard without losing any data. However, the Schema Generation Wizard is not able to differentiate between anticipated data loss and unanticipated data loss. When you run the wizard, a dialog box lists the tables and columns that contain data that will be dropped. You can either have the wizard continue and drop the data, or you can cancel the wizard and revise the changes you made to the tables and columns.

Supporting Cube and Dimension Changes

When you change the properties of dimensions and cubes, the Schema Generation Wizard regenerates the appropriate objects in the underlying subject area database, as well as in the related data source view, as described in the following table.

Deleting an object, such as a dimension, cube, or attribute.

The Schema Generation Wizard deletes the underlying objects to which the deleted object is mapped. If you add columns to a table that the wizard generated, the new columns do not prevent that table from being deleted.

Deleting an object causes the data stored in the underlying objects to be dropped, and may also cause other data to be dropped if referential integrity errors occur.

Renaming an object, such as a dimension, cube, or attribute.

The Schema Generation Wizard renames the underlying objects to which the renamed object is mapped. The wizard also renames all affected objects, such as primary keys. Existing data stored in the underlying objects is preserved.

Modifying an object, such as changing its data type.

The Schema Generation Wizard modifies the underlying objects to which the changed object is mapped. Existing data stored in the underlying objects in the databases is preserved, unless the new data type is incompatible with the existing data.

Adding a new object, such as a dimension, cube, or attribute.

The Schema Generation Wizard adds underlying objects to which the new object is mapped.

If the Schema Generation Wizard cannot make the required change because of the presence of a user object in the subject area database (because the Database Engine returns an error), the Schema Generation Wizard fails and displays the error returned by the Database Engine. For example, if you create a primary key constraint or a non-clustered index on a table after the wizard generated the table, the Schema Generation Wizard does not drop that table because it did not create the constraint or the index.

Supporting Schema Changes

When you change the properties of the tables or columns in the subject area database or in the associated data source view, the Schema Generation Wizard treats the changes as described in the following table.

Deleting a table or a column generated by the Schema Generation Wizard.

If you delete a table or a column generated by the Schema Generation Wizard, the wizard regenerates the deleted table. The wizard provides no warning that the deleted table or column will be regenerated.

Changing the properties of a table or column generated by the Schema Generation Wizard.

If you modify the properties of a table or a column generated by the Schema Generation Wizard, the wizard regenerates the changed table without the change. For example, if you change the data type or nullability of a column, or the filegroup of a table generated by the Schema Generation Wizard, the change does not survive the regeneration. The wizard provides no warning that the changed object will be regenerated without the change.

Adding a column to a table generated by the Schema Generation Wizard or adding a table to the subject area database or staging area database.

If you add a column to a table generated by the Schema Generation Wizard, the wizard preserves the additional column, along with any data stored in it, during regeneration. However, if you add a table to the subject area database or the staging area database, the Schema Generation Wizard does not incorporate the new table. The added column, or the added table, is not reflected in the Analysis Services project, the Analysis Services database, the DTS packages, the data source view, or any other place in the schema that is generated.

Supporting Data Source and Data Source View Changes

When the Schema Generation Wizard is rerun, it reuses the same data source and data source view that it used for the original generation. If you add a data source or a data source view, the wizard does not use it. If you delete the original data source or data source view after the initial generation, you must run the wizard from the beginning. All previous settings in the wizard are also deleted. Any existing objects in an underlying database that were bound to a deleted data source or data source view are treated as user-created objects the next time you run the Schema Generation Wizard.

If the data source view does not reflect the actual state of the underlying database at the time of generation, the Schema Generation Wizard may encounter errors when it generates the schemas for the subject area database and the staging area database. For example, if the data source view specifies that the data type for a column is set to **int**, but the data type for the column is actually set to **string**, the Schema Generation Wizard sets the data type for the foreign key to **int** to match the data source view and then fails when it creates the relationship because the actual data type is **string**.

On the other hand, if you change the data source connection string to a different database from the previous generation, no error is generated. The new database is used, and no change is made to the previous database.

[Understanding Incremental Generation](#)

Dimensions in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

A database dimension is a collection of related objects, called attributes, which can be used to provide information about fact data in one or more cubes. For example, typical attributes in a product dimension might be product name, product category, product line, product size, and product price. These objects are bound to one or more columns in one or more tables in a data source view. By default, these attributes are visible as attribute hierarchies and can be used to understand the fact data in a cube. Attributes can be organized into user-defined hierarchies that provide navigational paths to assist users when browsing the data in a cube.

Cubes contain all the dimensions on which users base their analyses of fact data. An instance of a database dimension in a cube is called a cube dimension and relates to one or more measure groups in the cube. A database dimension can be used multiple times in a cube. For example, a fact table can have multiple time-related facts, and a separate cube dimension can be defined to assist in analyzing each time-related fact. However, only one time-related database dimension needs to exist, which also means that only one time-related relational database table needs to exist to support multiple cube dimensions based on time.

Defining Dimensions, Attributes, and Hierarchies

The simplest method for defining database and cube dimensions, attributes, and hierarchies is to use the Cube Wizard to create dimensions at the same time that you define the cube. The Cube Wizard will create dimensions based on the dimension tables in the data source view that the wizard identifies or that you specify for use in the cube. The wizard then creates the database dimensions and adds them to the new cube, creating cube dimensions.

When you create a cube, you can also add to the new cube any dimensions that already exist in the database. These dimensions may have been previously defined for another cube or by the Dimension Wizard. After a database dimension has been defined, you can modify and configure the database dimension in Dimension Designer. You can also customize the cube dimension, to a limited extent, in Cube Designer.

NOTE

You can also design and configure dimensions, attributes, and hierarchies programmatically by using either XMLA or Analysis Management Objects (AMO). For more information, see [Analysis Services Scripting Language \(ASSL for XMLA\)](#) and [Developing with Analysis Management Objects \(AMO\)](#).

[Cubes in Multidimensional Models](#)

Create a Dimension Using the Dimension Wizard

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can create a new dimension by using the Dimension Wizard in Visual Studio with Analysis Services projects.

To create a new dimension

1. In **Solution Explorer**, right-click **Dimensions**, and then click **New Dimension**.
2. On the **Select Creation Method** page of the Dimension Wizard, select **Use an existing table**, and then click **Next**.

NOTE

You might occasionally have to create a dimension without using an existing table. For more information, see [Create a Dimension by Generating a Non-Time Table in the Data Source](#) and [Create a Time Dimension by Generating a Time Table](#).

3. On the **Specify Source Information** page, do the following procedures:
 - a. In the **Data source view** list, select a data source view.
 - b. In the **Main table** list, select the main dimension table.
 - c. In the **Key columns** list, review the key columns that the wizard has automatically selected based on the primary key that is defined in the main dimension table. To change this default setting, specify the key columns that link the dimension table to the fact table.
 - d. In the **Name column** drop-down list, review the name column that the wizard has automatically selected.

This default name is appropriate when the column contains descriptive information. However, you might want to specify a name that contains values that are more meaningful for the end user. For example, if a product category attribute in a Products dimension uses the **ProductCategoryKey** column as its key column, you can specify the **ProductCategoryName** column as its name column.

If the **Key columns** list contains multiple key columns, you must specify a name column that provides the member values for the key attribute. To do this, you can create a named calculation in the data source view and use that as the name column.

4. On the **Select Related Tables** page, select the related tables that you want to include in your dimension, and then click **Next**.

NOTE

The **Select Related Tables** page appears if the main dimension table that you specified has relationships to other dimension tables.

5. On the **Select Dimension Attributes** page, select the attributes that you want to include in the dimension, and then click **Next**.

Optionally, you can change the attribute names, enable or disable browsing, and specify the attribute type.

NOTE

To make the **Enable Browsing** and **Attribute Type** fields of an attribute active, the attribute must be selected for inclusion in the dimension.

6. On the **Define Account Intelligence** page, in the **Built-In Account Types** column, select the account type, and then click **Next**.

The account type must correspond to the account type of the source table that is listed in the **Source Table Account Types** column.

NOTE

The **Define Account Intelligence** page appears if you defined an **Account Type** dimension attribute on the **Select Dimension Attributes** page of the wizard.

7. On the **Completing the Wizard** page, enter a name for the new dimension and review the dimension structure. If you want to make changes, click **Back**; otherwise, click **Finish**.

NOTE

You can use Dimension Designer after you complete the Dimension Wizard to add, remove, and configure attributes and hierarchies in the dimension.

See Also

[Create a Dimension by Using an Existing Table](#)

Create a Dimension by Using an Existing Table

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, you can use the Dimension Wizard in Visual Studio with Analysis Services projects to create a dimension from an existing table. You do this by selecting the **Use an existing table** option on the **Select Creation Method** page of the wizard. If you select this option, the wizard bases the dimension structure on the dimension tables, their columns, and any relationships between those columns in an existing data source view. The wizard samples the data in the source table and related tables. It uses this data to define attribute columns that are based on the columns in the dimension tables, and to define hierarchies of attributes (called *user-defined* hierarchies). After you use the Dimension Wizard to create your dimension, you can use Dimension Designer to add, remove, and configure attributes and hierarchies in the dimension.

When you are using an existing table to create a dimension, the Dimension Wizard guides you through the following:

- Specifying the source information
- Selecting related tables
- Selecting dimension attributes
- Defining account intelligence

NOTE

For the step-by-step instructions that correspond to the information presented in this topic, see [Create a Dimension Using the Dimension Wizard](#).

Specifying the Source Information

You specify the source information on the **Specify Source Information** page. You begin this process by selecting the data source view that contains the table on which you want the dimension to be based. You then specify the main dimension table for the dimension that you are defining. The main dimension table is the table that is directly linked to the fact table. For example, specify a Product table as the main table for a Products dimension, or an Employee table for an Employees dimension. The wizard automatically selects a key column that is based on the primary key in the data source view. However, you can change the key column as appropriate. The key column determines the members of the dimension. For example, you would define ProductKey as the key column for a Product dimension.

Optionally, you can define a column that contains the member name. By default, the member name that will be displayed to users is the value from the key column. The values in a key column, such as ProductID or EmployeeID, are often unique, system-generated keys that are meaningless to the user. You can often provide more meaningful information to the user if you change the name that users see to a corresponding value in some other column in the dimension. For example, you can define a member name column that contains product or employee names. If you change the member name, users see a more descriptive name, but queries still use the key column values to correctly distinguish members that share the same name. If you specify a composite key for the key column, you must also specify the column that provides the member values for the key attribute. For more information about how to configure attribute properties, see [Dimension Attribute Properties Reference](#).

Selecting Related Tables

NOTE

The wizard skips this step if the main dimension table has no relationships defined in the data source view to other dimension tables.

If you are building a snowflake dimension, you specify the related tables from which additional attributes will be defined on the **Select Related Tables** page. For example, you are building a customer dimension in which you want to define a customer geography table. In this case, you might define a geography table as a related table.

Selecting Dimension Attributes

After selecting the dimension tables, you use the **Select Dimension Attributes** page to select the attributes that you want to include in the dimension from these tables. All of the underlying columns from all these tables are available as potential dimension attributes. The dimension key attribute must be selected and enabled for browsing.

By default, the wizard sets the type of an attribute to **Regular**. However, you might want to map specific attributes to a different attribute type that better represents the data. For example, the dbo.DimAccount table in the Adventure Works DW sample database contains an AccountCodeAlternateKey column that provides the account number. Instead of setting the type to **Regular** for this attribute, you might want to map this attribute to the **Account Number** type.

NOTE

If the dimension type and standard attribute types are not set when you create the dimension, use the Business Intelligence Wizard to set these values after you create the dimension. For more information, see [Add Dimension Intelligence to a Dimension](#) or (for an Accounts type dimension) [Add Account Intelligence to a Dimension](#).

The wizard automatically sets the dimension type based on the attribute types that are specified. The attribute types specified in the wizard set the **Type** property for the attributes. The **Type** property settings for the dimension and its attributes provide information about the contents of a dimension to server and client applications. In some cases, these **Type** property settings only provide guidance for client applications and are optional. In other cases, as for Accounts, Time, or Currency dimensions, these **Type** property settings determine specific server-based behavior and might be required to implement certain cube behavior.

For more information about dimension and attribute types, see [Dimension Types, Configure Attribute Types](#).

Defining Account Intelligence

NOTE

The Dimension Wizard displays this step only if you defined an **Account Type** dimension attribute on the **Select Dimension Attributes** page of the wizard.

You use the **Define Account Intelligence** page to create an Account type dimension. If you are creating an Account type dimension, you have to map standard account types supported by Analysis Services to members of the account type attribute in the dimension. The server uses these mappings to provide separate aggregation functions and aliases for each type of account data.

To map these account types, the wizard provides a table with the following columns:

- The **Source Table Account Types** column lists account types from the data source table.
- The **Built-In Account Types** column lists the corresponding standard account types supported by the server. If the source data uses standard names, the wizard automatically maps the source type to the server type, and populates the **Built-In Account Types** column with this information. If the server does not map the account types or you want to change the mapping, select a different type from the list in the **Built-In Account Types** column.

NOTE

If the account types are not mapped when the wizard creates an Accounts dimension, use the Business Intelligence Wizard to configure these mappings after you create the dimension. For more information, see [Add Account Intelligence to a Dimension](#).

Completing the Wizard

The wizard scans dimension tables to detect relationships. The wizard will create attribute relationships between key attributes in snowflake dimensions automatically.

The wizard also automatically detects if a parent-child relationship exists in the dimension. A parent-child relationship exists when a parent attribute references members of the key attribute of the dimension. This relationship defines hierarchical relationships and aggregation paths between leaf members of the dimension. For more information about parent-child hierarchies, see [Attributes in Parent-Child Hierarchies](#).

On the **Completing the Wizard** page, you complete the wizard by typing a name for the new dimension and reviewing the dimension structure.

[Create a Dimension by Generating a Non-Time Table in the Data Source](#)

Create a Time Dimension by Generating a Time Table

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, you can use the Dimension Wizard in Visual Studio with Analysis Services projects to create a time dimension when no time table is available in the source database. You do this by selecting one of the following options on the **Select Creation Method** page:

- **Generate a time table in the data source** Select this option when you have permission to create objects in the underlying data source. The wizard will then generate a time table and store this table in the data source. The wizard then creates the time dimension from this time table.
- **Generate a time table on the server** Select this option when you do not have permission to create objects in the underlying data source. The wizard will then generate and store a table on the server instead of in the data source. (The dimension created from a time table on the server is called a *server time dimension*.) The wizard then creates the server time dimension from this table.

When you create a time dimension, you specify the time periods, and also the start and end dates for the dimension. The wizard uses the specified time periods to create the time attributes. When you process the dimension, Analysis Services generates and stores the data that is required to support the specified dates and periods. The wizard uses the attributes created for a time dimension to recommend hierarchies for the dimension. The hierarchies reflect the relationships between different time periods and take account of different calendars. For example, in a standard calendar hierarchy, a Weeks level appears under a Years level but not under a Months level, because weeks divide evenly into years but not into months. In contrast, in a manufacturing or reporting calendar hierarchy, weeks divide evenly into months, so a Weeks level appears under a Months level.

Define Time Periods

You use the **Define Time Periods** page of the wizard to specify the range of dates that you want to include in the dimension. For example, you might select a range that starts on January 1 of the earliest year in your data and that ends one or two years beyond the current year (to allow for future transactions). Transactions that are outside the range either do not appear or appear as unknown members in the dimension, depending on the **UnknownMemberVisible** property setting for the dimension. You can also change the first day of the week used by your data (the default is Sunday).

Select the time periods to use when the wizard creates the hierarchies that apply to your data, such as Years, Half Years, Quarters, Trimesters, Months, Ten Days, Weeks, or Date. You must always select at least the Date time period. The Date attribute is the key attribute for the dimension, so the dimension cannot function without it.

Next to **Language for time member names**, select the language to be used to label the members of the dimension.

After you create a time dimension that is based on a range of dates, you can use Dimension Designer to add or remove time attributes. Because the Date attribute is the key attribute for the dimension, you cannot remove it from the dimension. To hide the Date attribute from users, you can change the **AttributeHierarchyVisible** property on the attribute to **False**.

Select Calendars

The standard (Gregorian) 12-month calendar, starting on January 1 and ending on December 31, is always included when you create a time dimension. On the **Select Calendars** page of the wizard, you can specify additional calendars on which to base hierarchies in the dimension. For descriptions of the calendar types, see [Create a Date type Dimension](#).

Depending on which time periods you select on the **Define Time Periods** page of the wizard, the calendar selections determine attributes that are created in the dimension. For example, if you select the **Year** and **Quarter** time periods on the **Define Time Periods** page of the wizard and select **Fiscalcalendar** on the **Select Calendars** page, the FiscalYear, FiscalQuarter, and FiscalQuarterOfYear attributes are created for the fiscal calendar.

The wizard also creates calendar-specific hierarchies that are composed of the attributes that are created for the calendar. For every calendar, each level in every hierarchy rolls up into the level above it. For example, in the standard 12-month calendar, the wizard creates a hierarchy of Years and Weeks or Years and Months. However, weeks are not contained evenly within months in a standard calendar, so there is no hierarchy of Years, Months, and Weeks. In contrast, weeks in a reporting or manufacturing calendar are evenly divided into months, so in these calendars weeks roll up into months.

Completing the Dimension Wizard

On the **Completing the Wizard** page, review the attributes and hierarchies created by the wizard, and then name the time dimension. Click **Finish** to complete the wizard and create the dimension. After you complete the dimension, you can change it by using Dimension Designer.

Create a Dimension by Generating a Non-Time Table in the Data Source

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In Microsoft SQL Server Analysis Services, you can use the Dimension Wizard in Visual Studio with Analysis Services projects to create a dimension without using an existing data source. You do this by selecting the **Generate a non-time table in the data source** option of the **Select Creation Method** page of the wizard. To create a new dimension table in the underlying data source, you must have permission to create objects in the underlying data source. When defining a dimension without a predefined data source view, you can either define the dimension from scratch or use a dimension template.

The Dimension Wizard provides sample dimension templates from which you can build a common dimension type. You can select from the following types of dimensions:

- Account
- Customer
- Date
- Department
- Destination Currency
- Employee
- Geography
- Internet Sales Order Details
- Organization
- Product
- Promotion
- Reseller Sales Order Details
- Reseller
- Sales Channel
- Sales Reason
- Sales Summary Order Details
- Sales Territory
- Scenario
- Source Currency

Each of the standard templates supports attributes that you can choose to include in the dimension. You can also add your own template files for dimensions that are commonly used with your data. The dimension templates are located in the following folder:

You can use Dimension Designer after you complete the Dimension Wizard to add, remove, and configure attributes and hierarchies in the dimension.

When you are creating a non-time dimension without using a data source, the Dimension Wizard guides you through the steps of specifying the dimension type, and identifying the key attribute and slowly changing dimensions.

Specify Dimension Type

On the **Specify Dimension Type** page of the Dimension Wizard, you can specify the dimension type. If you are building the dimension based on a template, the dimension type is defined for you. On this page, you can also select standard attributes for the specified dimension type if any are available.

If you selected a template that corresponds to a dimension type, this page is populated with the options for that dimension type. If you did not select a template, or if there is no corresponding dimension type, the default dimension type is **Regular**. If a dimension type is not already selected, select the most appropriate type for the dimension that you are creating. If no appropriate type is listed for **Dimension type**, use **Regular**.

When you select a dimension type, the wizard lists the attribute types that apply to this dimension under **Dimension attributes**. To select an attribute type, select the **Include** check box next to the attribute type, and type the name for the attribute under **Dimension Attribute**. The default name is the same as **Attribute Type**.

Identify Key Attribute and Changing Dimensions

On the **Specify Dimension Key and Type** page, select the attribute that you want to be the key attribute for the dimension. The key attribute typically corresponds to the primary key column in the main dimension table, and it typically indexes the leaf members of the dimension.

If you selected a template, and a key attribute is defined in the template, that attribute is the default key attribute. If you selected a template but no key attribute is defined in the template, the default is the first attribute in the list. The list contains all the attributes that you selected on the **Specify Dimension Type** page. You can select any one of the attributes that you selected on the **Specify Dimension Type** page to be the key attribute. If you did not select any attributes, the wizard automatically creates a key attribute and names it by concatenating the dimension name and "ID".

Finally, specify whether this dimension is a changing dimension. Members in a changing dimension move over time to different locations in the hierarchy. The wizard generates additional columns and creates attributes that correspond to those columns. These columns will let users query the dimension in such a way as to factor in the change. Any packages that you subsequently create with the Schema Generation Wizard manage surrogate keys based on slowly changing dimension characteristics of the dimension.

When you select the **This is a changing dimension** check box, the Dimension Wizard defines the attributes indicated in the following table:

| ATTRIBUTE | TYPE |
|----------------|---------------|
| SCD OriginalID | SCDOriginalID |
| SCD End Date | SCDEndDate |
| SCD Start Date | SCDStartDate |
| SCD Status | SCDStatus |

By default, the **This is a changing dimension** check box is selected if you use a template that has these slowly changing dimension attributes defined. If you clear the check box, the slowly changing dimension attributes are removed from the dimension.

You can use Dimension Designer to configure properties for a slowly changing dimension.

Completing the Dimension Wizard

On the **Completing the Wizard** page, type a name for the new dimension and view the dimension structure. Select the **Generate schema now** check box to start the Schema Generation Wizard after you click **Finish**. In most cases, you should not select this check box if you plan to create additional objects. If you do not select this check box, you can use Dimension Designer to generate the schema later.

[Create a Time Dimension by Generating a Time Table](#)

Define Database Dimensions

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use Dimension Designer in Visual Studio with Analysis Services projects to configure an existing database dimension in a Microsoft SQL Server Analysis Services project or database. You can use Dimension Designer to do the following:

- Configure the dimension-level properties.
- Add and configure dimension attributes.
- Define and configure user-defined hierarchies.
- Define and configure relationships between attributes.
- Define dimension translations.
- For processed dimensions, you can browse the dimension structure and view data.

After you modify a dimension, attribute, or hierarchy, you must process that dimension to view the changes. When working in project mode, you deploy the changes to the Analysis Services instance before processing.

For more information about how to open a dimension in Dimension Designer, see [Modify or Delete a Database Dimension in Solution Explorer](#).

Dimension Designer has three different tabs, which are described in the following table.

| TAB | DESCRIPTION |
|--------------------------------|---|
| Dimension Structure | Use this tab to work with the structure of a dimension—to examine or create the data source view schema for a dimension, to work with attributes, and to organize attributes in user-defined hierarchies. |
| Attribute Relationships | Use this tab to create, modify, or delete the attribute relationships of a dimension. |
| Translations | Use this tab to add and edit translations of dimension metadata in different languages. |
| Browser | Use this tab to examine the members of a processed dimension and to review translations of dimension metadata. |

The following topics describe the tasks that you can perform in Dimension Designer.

[Dimension Attribute Properties Reference](#)

Describes how to define and configure a dimension attribute.

[Create User-Defined Hierarchies](#)

Describes how to define and configure a user-defined hierarchy.

[Define Attribute Relationships](#)

Describes how to define and configure an attribute relationship.

[Use the Business Intelligence Wizard to Enhance Dimensions](#)

Describes how to use the Business Intelligence Wizard to enhance a dimension.

Database Dimensions - Configure the (All) Level for Attribute Hierarchies

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In Microsoft SQL Server Analysis Services, the (All) level is an optional, system-generated level. It contains only one member whose value is the aggregation of the values of all members in the immediately subordinate level. This member is called the All member. It is a system-generated member that is not contained in the dimension table. Because the member in the (All) level is at the top of the hierarchy, the member's value is the consolidated aggregation of the values of all members in the hierarchy. The All member often serves as the default member of a hierarchy.

The presence of an (All) level in an attribute hierarchy depends on the **IsAggregatable** property setting for the attribute and the presence of an (All) level in a user-defined hierarchy depends on the **IsAggregatable** property of the attribute at the top-most level of user-defined hierarchy. If the **IsAggregatable** property is set to **True**, an (All) level will exist. A hierarchy has no (All) level if the **IsAggregatable** property is set to **False**.

Establishing the Topmost Level

If the **IsAggregatable** property is set to **False** on the source attribute of a level in a hierarchy, then no aggregatable level can appear in the hierarchy above that level. A non-aggregatable level must be the topmost level of any hierarchy or the **IsAggregatable** property of the source attributes for any levels above it must also be set to **False**.

All Member and (All) Level

The single member of the (All) level is called the All member. The **AttributeAllMemberName** property on a dimension specifies the name of the All member for attributes in a dimension. The **AllMemberName** property on a hierarchy specifies the name of the All member for the hierarchy.

Database Dimensions - Modify or Delete a Database Dimension in Solution Explorer

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can modify or delete a dimension by using Dimension Designer in Visual Studio with Analysis Services projects. When you modify a dimension, your changes are not available to users until you process the dimension. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To modify a dimension in SQL Server Data Tools

1. In Solution Explorer, right-click the dimension that you want to modify, and then click **Open**.
2. On the **Dimension Structure** tab, in the **Attributes**, **Hierarchies**, or **Data Source View** panes, click the item that you want to modify, and then make the changes.

For more information about the types of changes that you can make, see [Processing a multidimensional model \(Analysis Services\)](#).

To delete a dimension in SQL Server Data Tools

- In Solution Explorer, right-click the dimension that you want to delete, and then click **Delete**.

[Dimensions in Multidimensional Models](#)

Database Dimensions - Browse Dimension Data in Dimension Designer

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can browse the data in a dimension by using the **Browser** view in Dimension Designer, which is accessed from Visual Studio with Analysis Services projects.

In order for dimension data to be displayed in the **Browser** view, the dimension must be in a processed state. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To browse a dimension in SQL Server Data Tools

1. Open the dimension that you want to browse, and click the **Browser** tab.
2. In the **Hierarchy** drop-down list, choose the hierarchy for which you want to browse data.
3. Optionally, if your dimension includes translations, in the **Language** drop-down list, choose the language in which you want to display the data.

NOTE

You must have a translation defined in the dimension for the selected language.

[Dimensions in Multidimensional Models](#)

Database Dimensions - BI Wizard in Dimension Designer

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In Microsoft SQL Server Analysis Services, you create custom rollup operators and custom member formulas and configure dimensions for writeback by using the Business Intelligence Wizard or Dimension Designer. You can start the Business Intelligence Wizard from Solution Explorer or from Cube Designer in Visual Studio with Analysis Services projects. Dimension Designer can be accessed from Visual Studio with Analysis Services projects.

To start the Business Intelligence Wizard

- Open the dimension to which you want to add business intelligence, and on the toolbar, click the **Add Business Intelligence** button. Alternatively, you can right-click the dimension in either Object Explorer or Solution Explorer, and then click **Add Business Intelligence**.

Database Dimensions - Create a Date type Dimension

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, a time dimension is a dimension type whose attributes represent time periods, such as years, semesters, quarters, months, and days. The periods in a time dimension provide time-based levels of granularity for analysis and reporting. The attributes are organized in hierarchies, and the granularity of the time dimension is determined largely by the business and reporting requirements for historical data. For example, most financial and sales data in business intelligence applications use a monthly or quarterly granularity.

Typically, cubes in Analysis Services incorporate a time dimension in one form or another. A cube may include more than one time dimension, or several hierarchies from the same time dimension, depending on the granularity of the data and the reporting requirements. However, not all cubes require a time dimension. Some OLAP applications, such as activity-based costing, do not require a time dimension, because .costing in an activity-based dimension is based on activity instead of time.

Dimension Structure

The dimension structure for a time dimension depends on how the underlying data source stores the time period information. This difference in storage produces two basic types of time dimensions:

Time dimension

Time dimensions are similar to other dimensions in that a dimension table supplies the attributes for the dimension. Each column in the dimension main table defines an attribute for a specific time period.

Like other dimensions, the fact table has a foreign key relationship to the dimension table for the time dimension. The key attribute for a time dimension is based either on an integer key or on the lowest level of detail, such as the date, that appears in the dimension main table.

Server time dimension

If you do not have a dimension table to which to bind time-related attributes, you can have Analysis Services define a server time dimension based on time periods. To define the hierarchies, levels, and members represented by the server time dimension, you select standard time periods when you create the dimension.

Attributes in a server time dimension have a special time-attribute binding. Analysis Services uses the attribute types that are related to dates, such as Year, Month, or Day, to define members of attributes in a time dimension.

After you include the server time dimension in a cube, you set the relationship between the measure group and the server time dimension by specifying a relationship on the **Define Dimension Usage** page of the Cube Wizard.

Calendars

In a time dimension or server time dimension time period attributes are grouped together in hierarchies. Such hierarchies are generally referred to as calendars.

Business intelligence applications frequently require multiple calendar definitions. For example, a human resource department may track employees by using a *standard* calendar-a twelve-month Gregorian calendar starting on January 1 and ending on December 31st. However, that same human resource department may track expenditures by using a *fiscal* calendar-a twelve-month calendar that defines the fiscal year used by the

organization.

You can construct these different calendars manually in Dimension Designer. However, the Dimension Wizard provides several hierarchy templates that can be used to automatically generate several types of calendars when you create a time dimension or server time dimension. The following table describes the various calendars that can be generated by the Dimension Wizard.

| CALENDAR | DESCRIPTION |
|--|---|
| Standard calendar | <p>A twelve-month Gregorian calendar starting on January 1 and ending on December 31st.</p> <p>Regardless of whether you use the Dimension Wizard to create a time dimension or a server time dimension, the wizard generates a hierarchy for a standard calendar after you define the attributes that represent the time periods for the dimension. If you use the Dimension Wizard to create a server time dimension, you can adjust the starting date of the standard calendar to start on a day other than January 1.</p> |
| Fiscal calendar | <p>A twelve-month fiscal calendar. When you select this calendar, specify the starting day and month for the fiscal year used by your organization.</p> <p>Note: This calendar is only available if you use the Dimension Wizard to create a server time dimension.</p> |
| Reporting calendar (or marketing calendar) | <p>A twelve-month reporting calendar that includes two months of four weeks and one month of five weeks in a repeated three-month (quarterly) pattern. When you select this calendar, specify the starting day and month and the three-month pattern of 4-4-5, 4-5-4, or 5-4-4 weeks, where each digit represents the number of weeks in a month.</p> <p>Note: This calendar is only available if you use the Dimension Wizard to create a server time dimension.</p> |
| Manufacturing calendar | <p>A calendar that uses 13 periods of four weeks, divided into three quarters of three periods and one quarter of four periods. When you select this calendar, you specify the starting week (between 1 and 4) and month for the manufacturing year used by your organization, and also identify which quarter contains four periods.</p> <p>Note: This calendar is only available if you use the Dimension Wizard to create a server time dimension.</p> |
| ISO 8601 Calendar | <p>The International Organization for Standardization (ISO) Representation of Dates and Time standard calendar (8601). This calendar has an integral number of 7-day weeks. The new year may start several days before or after the start of the new year, based on the Gregorian calendar. The first week of this calendar is determined by the first week of the Gregorian calendar which contains a Thursday. Therefore, the first day of this week, the Sunday, may actually fall within the previous year.</p> <p>Note: This calendar is only available if you use the Dimension Wizard to create a server time dimension.</p> |

When you create a server time dimension, and specify the time periods and the calendars to use in that

dimension, the Dimension Wizard adds the attributes for the time periods that are appropriate for each specified calendar. For example, if you create a server time dimension that uses years as the time period and includes both fiscal and reporting calendars, the wizard will then add FiscalYear and ReportingYears attributes, together with the standard Years attribute, to the dimension. A server time dimension will also have attributes for combinations of selected time periods, such as a DayOfWeek attribute for a dimension that contains Days and Weeks. The Dimension Wizard creates a calendar hierarchy by combining attributes that belong to a single calendar type. For example, a fiscal calendar hierarchy may contain the following levels: Fiscal Year, Fiscal Half Year, Fiscal Quarter, Fiscal Month, and Fiscal Day.

Adding Time Intelligence with the Business Intelligence Wizard

After you have defined a time dimension and added that dimension to a cube, you can use the Business Intelligence Wizard to add time intelligence functionality, such as period-to-date, period-to-period, and rolling average measures. For more information, see [Define Time Intelligence Calculations using the Business Intelligence Wizard](#).

NOTE

You cannot use the Business Intelligence Wizard to add time intelligence to server time dimensions. The Business Intelligence Wizard adds a hierarchy to support time intelligence, and this hierarchy must be bound to a column of the time dimension table. Server time dimensions do not have a corresponding time dimension table and therefore cannot support this additional hierarchy.

[Dimension Types](#)

Database Dimensions - Finance Account of parent-child type

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, an account type dimension is a dimension whose attributes represent a chart of accounts for financial reporting purposes.

An account dimension lets you selectively manage aggregation behavior across accounts over time. An account dimension also lets use a standard mechanism to resolve most of the nonstandard aggregation issues typically encountered in business intelligence solutions that handle financial data. If you did not have such a standard mechanism, resolving these nonstandard aggregation issues would require custom rollup formulas, calculated members, or Multidimensional Expressions (MDX) scripts.

To identify a dimension as an account dimension, set the **Type** property of the dimension to **Accounts**.

Dimension Structure

An account dimension contains, at least, two attributes:

- A key attribute—an attribute that identifies individual accounts in the dimension table for the account dimension.
- An account attribute—a parent attribute that describes how accounts are hierarchically arranged in the account dimension.

To identify an attribute as an account attribute, set the **Type** property of the attribute to **Account** and the **Usage** property to **Parent**.

Account dimensions can optionally contain the following attributes:

- An account type attribute—an attribute that defines the account type for each account in the dimension. The member names of the account type attribute map to the account types defined for the Analysis Services database or project, and indicate the aggregation function used by Analysis Services for those accounts. You can also use unary operators or custom rollup formulas to determine aggregation behavior for account attributes, but account types let you to easily apply consistent behavior to a chart of accounts without requiring changes to the underlying relational database.

To identify an account type attribute, set the **Type** property of the attribute to **AccountType**.

- An account name attribute—an attribute that is used for reporting purposes. You identify an account name attribute by setting the **Type** property of the attribute to **AccountName**.
- An account number attribute—an attribute that is used for reporting purposes. You identify an account number attribute by setting the **Type** property of the attribute to **AccountNumber**.

For more information about attribute types, see [Configure Attribute Types](#).

Adding Account Intelligence with the Business Intelligence Wizard

After you have defined an account dimension and added that dimension to a cube, you can use the Business Intelligence Wizard to adding account intelligence functionality, such as identifying and mapping account types, to

the dimension. For more information, see [Add Account Intelligence to a Dimension](#).

See Also

[Attributes and Attribute Hierarchies](#)

[Business Intelligence Wizard F1 Help](#)

[Dimension Types](#)

Database Dimensions - Create a Currency type Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In Microsoft SQL Server Analysis Services, a currency type dimension is a dimension whose attributes represent a list of currencies for financial reporting purposes.

A currency dimension lets you add currency conversion capabilities to a cube in Analysis Services. To add currency conversion to a cube, you use the Business Intelligence Wizard define a Multidimensional Expressions (MDX) script command that converts currency measures to values that are appropriate for the locale of the client application. To create this MDX script, the Business Intelligence Wizard needs the following information:

- A currency dimension that represents source currencies. (This dimension is the source currency dimension.)
- A measure group that represents the exchange rates that will be used.

From this information, the Business Intelligence Wizard will design a currency conversion process that identifies the appropriate destination currency dimension (the currency dimension that represents destination currencies). Depending on the number of currency conversions that your business intelligence solution requires, the Business Intelligence Wizard can define multiple destination currency dimensions. For more information about defining currency conversions, see [Currency Conversions \(Analysis Services\)](#).

To identify a dimension as a currency dimension, set the **Type** property of the dimension to **Currency**.

Dimension Structure

A currency dimension contains, at least, a key attribute identifying individual currencies in the dimension table for the currency dimension. The value of the key attribute is different in both source and destination currency dimensions:

- To identify an attribute as the key attribute of a source currency dimension, set the **Type** property of the attribute to **CurrencySource**.
- To identify an attribute as the destination currency dimension, set the **Type** property of the attribute to **CurrencyDestination**.

For reporting purposes, both source and destination currency dimensions can optionally contain the following attributes:

- A currency name attribute.

To identify an attribute as a currency name attribute, set the **Type** property of the attribute to **CurrencyName**.

- A currency source attribute.

To identify an attribute as a currency source attribute, set the **Type** property of the attribute to **CurrencySource**.

- A currency International Standards Organization (ISO) code.

To identify an attribute as a currency ISO code attribute, set the **Type** property of the attribute to

CurrencyIsoCode

For more information about attribute types, see [Configure Attribute Types](#).

Defining Account Intelligence with the Business Intelligence Wizard

After you have defined an account dimension and added that dimension to a cube, you can use the Business Intelligence Wizard to add account intelligence functionality, such as identifying and mapping account types, to the dimension. For more information, see [Add Account Intelligence to a Dimension](#).

[Dimension Types](#)

Dimension Attribute Properties Reference

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, there are many properties that determine how dimensions and dimension attributes function. The following table lists and describes each of these attribute properties.

| PROPERTY | DESCRIPTION |
|---|--|
| AttributeHierarchyDisplayFolder | Identifies the folder in which to display the associated attribute hierarchy to end users. |
| AttributeHierarchyEnabled | Determines whether an attribute hierarchy is generated by Analysis Services for the attribute. If the attribute hierarchy is not enabled, the attribute cannot be used in a user-defined hierarchy and the attribute hierarchy cannot be referenced in Multidimensional Expressions (MDX) statements. |
| AttributeHierarchyOptimizedState | Determines the level of optimization applied to the attribute hierarchy. By default, an attribute hierarchy is FullyOptimized , which means that Analysis Services builds indexes for the attribute hierarchy to improve query performance. The other option, NotOptimized , means that no indexes are built for the attribute hierarchy. Using NotOptimized is useful if the attribute hierarchy is used for purposes other than querying, because no additional indexes are built for the attribute. Other uses for an attribute hierarchy can be helping to order another attribute. |
| AttributeHierarchyOrdered | Determines whether the associated attribute hierarchy is ordered. The default value is True . However, if an attribute hierarchy will not be used for querying, you can save processing time by changing the value of this property to False . |
| AttributeHierarchyVisible | Determines whether the attribute hierarchy is visible to client applications. The default value is True . However, if an attribute hierarchy will not be used for querying, you can save processing time by changing the value of this property to False . |
| CustomRollupColumn | Specifies the column that defines a custom rollup formula. |
| CustomRollupPropertiesColumn | Specifies the column that contains the properties of a custom rollup formula. |
| DefaultMember | Specifies a Multidimensional Expressions (MDX) expression that defines the default measure for the attribute. |
| Description | Contains the description of the attribute. |

| PROPERTY | DESCRIPTION |
|----------------------------------|--|
| DiscretizationBucketCount | Contains the number of buckets into which to discretize. |
| DiscretizationMethod | Defines the method to use for discretization. |
| EstimatedCount | Specifies the estimated number of members in the attribute. Until you run the Aggregation Design Wizard, the default value is zero. Either you can allow the wizard to count the number of records or you can enter an estimated value. Enter a value manually if you know the number of members and want to save the time that is required to query the database for the count. If you are working with a test subset of your production data, you can use the counts of your production data so that the aggregation design will be optimized for the production data instead of the test data. |
| GroupingBehavior | A user defined value that provides a hint to client applications on how to group attributes. |
| ID | Contains the unique identifier (ID) of the dimension. |
| InstanceSelection | <p>Provides a hint to client applications about how a list of items should be displayed, based on the expected number of items in the list. The available options are as follows:</p> <ul style="list-style-type: none"> None No hint is provided to the client application. This is the default value. DropDown The number of items is small enough to display in a drop-down list. List The number of items is too large for a drop-down list, but does not require filtering. FilteredList The number of items is large enough to require users to filter the items to be displayed. MandatoryFilter The number of items is so large that the display must always be filtered. |
| IsAggregatable | Specifies whether the values of the attribute members can be aggregated. The default value is True , which means that the attribute hierarchy contains an (All) level. If the value for this property is False , the attribute hierarchy does not contain an (All) level. |
| KeyColumns | Contains the column or columns that represent the key for the attribute, which is the column in the underlying relational table in the data source view to which the attribute is bound. The value of this column for each member is displayed to users unless a value is specified for the NameColumn property. |
| MemberNamesUnique | Determines whether member names in the attribute hierarchy must be unique. |

| PROPERTY | DESCRIPTION |
|-------------------------------|---|
| MembersWithData | <p>Used by parent attributes to determine whether to display data members for non-leaf members in the parent attribute. This property value is only used when the value of the Usage property is set to Parent. This means that a parent-child hierarchy has been defined. The available options are as follows:</p> <p>NonLeafDataHidden Non-leaf data is hidden.</p> <p>NonLeafDataVisible Non-leaf data is visible.</p> |
| MembersWithDataCaption | <p>Provides a template string that is used by parent attributes to create captions for system-generated data members in the parent attribute. This property value is only used when the value of the Usage property is set to Parent. This means that a parent-child hierarchy has been defined.</p> |
| Name | <p>Contains the user-friendly name of the attribute.</p> |
| NameColumn | <p>Identifies the column that provides the name of the attribute that is displayed to users, instead of the value in the key column for the attribute. This column is used when the key column value for an attribute member is cryptic or not otherwise useful to the user, or when the key column is based on a composite key. The NameColumn property is not used in parent-child hierarchies; instead, the NameColumn property for child members is used as the member names in a parent-child hierarchy.</p> |
| NamingTemplate | <p>Defines how levels are named in a parent-child hierarchy constructed from the parent attribute. This property value is only used when the value of the Usage property is set to Parent. This means that a parent-child hierarchy has been defined.</p> |
| OrderBy | <p>Describes how to order the members that are contained in the attribute hierarchy. The default value is Name, which specifies that ordering of the attribute members is based on the value of the NameColumn property, if any. Otherwise, members are ordered by the value of the key column. The available options are as follows:</p> <p>NameColumn Order by the value of the NameColumn property.</p> <p>Key Order by the value of the key column of the attribute member.</p> <p>AttributeKey Order by the value of the member key of a specified attribute, which must have an attribute relationship to the attribute.</p> <p>AttributeName Order by the value of the member name of a specified attribute, which must have an attribute relationship to the attribute.</p> |
| OrderByAttribute | <p>Identifies the attribute by which to order the members of the attribute hierarchy.</p> |

| PROPERTY | DESCRIPTION |
|----------------------------|--|
| RootMemberIf | <p>Determines how the root or topmost members of a parent-child hierarchy are identified. This property value is only used when the value of the Usage property is set to Parent. This means that a parent-child hierarchy has been defined. The default value is ParentIsBlankSelfOrMissing, which means that only members that meet one or more of the conditions described for ParentIsBlank, ParentIsSelf, or ParentIsMissing are treated as root members. The following values are also available:</p> <ul style="list-style-type: none"> ParentIsBlank Only members with a null, a zero, or an empty string in the key column or columns are treated as root members. ParentIsSelf Only members with themselves as parents are treated as root members. ParentIsMissing Only members with parents that cannot be found are treated as root members. |
| Type | <p>Contains the type of the attribute. For more information, see Configure Attribute Types.</p> |
| UnaryOperatorColumn | <p>Specifies the column that provides unary operators. It is a binding of DataItem type that defines the details of a column providing a unary operator.</p> |
| Usage | <p>Describes how an attribute is used.</p> <p>The available options are as follows:</p> <ul style="list-style-type: none"> Regular The attribute is a regular attribute. This is the default value. Key The attribute is a key attribute. Parent The attribute is a parent attribute. |
| ValueColumn | <p>Identifies the column that provides the value of the attribute. If the NameColumn element of the attribute is specified, the same DataItem values are used as default values for the ValueColumn element. If the NameColumn element of the attribute is not specified and the KeyColumns collection of the attribute contains a single KeyColumn element representing a key column with a string data type, the same DataItem values are used as default values for the ValueColumn element.</p> |

NOTE

For more information about how to set values for the **KeyColumn** property when you are working with null values and other data integrity issues, see [Handling Data Integrity Issues in Analysis Services 2005](#).

NOTE

The default member on an attribute is used to evaluate expressions when a member from the hierarchy is not explicitly included in a query. The default member for an attribute is specified by the **DefaultMember** property on the attribute. Whenever a hierarchy from a dimension is included in a query, all the default members from attributes corresponding to levels in the hierarchy are ignored. If no hierarchy of a dimension is included in a query, then default members are used for all the attributes in the dimension. For more information on default members, see [Define a Default Member](#).

Attribute Properties - Rename an Attribute

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

The name of an attribute in Microsoft SQL Server Analysis Services is defined by its **Name** property. To rename an attribute, right-click the attribute in the **Attributes** pane of the **Dimension Structure** tab of Dimension Designer in Visual Studio with Analysis Services projects, and then click **Rename**. If the **Attributes** pane is in grid view, click the attribute's name and edit it directly in the grid. You can also select an attribute and set its **Name** property in the **Properties** window.

For more information about how to rename an attribute, see [Bind an attribute to a Key column](#).

Attribute Properties – Add an Attribute to a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can add an attribute to a dimension either automatically or manually in Microsoft SQL Server Analysis Services.

To create an attribute automatically, on the **Dimension Structure** tab of Dimension Designer in Visual Studio with Analysis Services projects, select the column that you want to map to an attribute, and then drag that column from the **Data Source View** pane to the **Attributes** pane. This creates an attribute that is mapped to the column, and assigns the same name to the attribute as the name of the column. If an attribute that uses that name already exists, Analysis Services adds an ordinal number suffix, starting with "1" for the first duplicate name.

To create an attribute manually, set the **Attributes** pane to grid view. In the name column of the last row in the grid, click the <new attribute> item. Type a name for the new attribute. This creates an attribute that is not mapped to a column and that has default settings for all its properties. You can set the mapping in the **Properties** window of Visual Studio with Analysis Services projects by configuring the **KeyColumns** property for the new attribute.

For more information, see [Define a New Attribute Automatically](#), [Bind an Attribute to a Name Column](#), and [Modify the KeyColumn Property of an Attribute](#).

Attribute Properties - Remove an Attribute from a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

To remove an attribute from a dimension in Microsoft SQL Server Analysis Services, right-click the attribute in the **Attributes** pane of the **Dimension Structure** tab of Dimension Designer in Visual Studio with Analysis Services projects, and then click **Delete**. In the **Delete Objects** dialog box, click **OK**. This removes the attribute from the dimension, but does not affect the data source view for the dimension.

Attribute Properties - Configure Attribute Types

7/16/2019 • 12 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, attribute types help classify an attribute in terms of business functionality. There are many attribute types, most of which are used by client applications to display or support an attribute. However, some attribute types also have specific meaning to Analysis Services. For example, some attribute types identify attributes that represent time periods in various calendars for time dimensions.

Setting Attribute Types

The value of the **Type** property for an attribute determines the attribute type for that attribute. Several wizards in Analysis Services set attribute types when defining dimensions or attributes. These Analysis Services wizards also set attribute types when the wizards add functionality to dimensions. For example, the Business Intelligence Wizard applies several attribute types to attributes in a dimension when the wizard adds account intelligence to identify attributes that contain the names, codes, numbers, and structure of accounts in the dimension. The Business Intelligence Wizard also consumes attribute types, such as for currency conversion. For more information, see [Create a Currency type Dimension](#).

The following tables list the attribute types available in Analysis Services. These tables separate attribute types into the following categories:

| TERM | DEFINITION |
|--------------------------------------|--|
| General attribute types | These values are available to all attributes, and exist only to enable classification of attributes for client application purposes. |
| Account dimension attribute types | These values identify an attribute that belongs to an account dimension. For more information about account dimension, see Create a Finance Account of parent-child type Dimension . |
| Currency dimension attribute type | These values identify an attribute that belongs to a currency dimension. For more information about currency dimensions, see Create a Currency type Dimension . |
| Slowly changing dimension attributes | These values identify an attribute that belongs to a slowly changing dimension. |
| Time dimension attributes | These values identify an attribute that belongs to a time dimension. For more information about time dimensions, see Create a Date type Dimension . |

General Attribute Types

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|----------------------|--|
| Address | Represents an address. |
| AddressBuilding | Represents a building identifier for an address. |

| ATTRIBUTE TYPE | DESCRIPTION |
|-------------------------------|--|
| AddressCity | Represents a city for an address. |
| AddressCountry | Represents a country or region for an address. |
| AddressFax | Represents a fax telephone number. |
| AddressFloor | Represents a floor identifier for an address. |
| AddressHouse | Represents a house number for an address. |
| AddressPhone | Represents a telephone number. |
| AddressQuarter | Represents a quarter for an address. |
| AddressRoom | Represents a room identifier for an address. |
| AddressStateOrProvince | Represents a state or province for an address. |
| AddressStreet | Represents the street for an address. |
| AddressZip | Represents a ZIP Code or Postal Code for an address. |
| BomResource | Represents a resource for a bill of materials (BOM). |
| Caption | Represents a caption. |
| CaptionAbbreviation | Represents an abbreviation. |
| CaptionDescription | Represents a description. |
| Channel | Represents a channel. |
| City | Represents a city. |
| Company | Represents a company. |
| Continent | Represents a continent. |
| Country | Represents a country or region. |
| County | Represents a county. |
| CustomerGroup | Represents a group of customers. |
| CustomerHousehold | Represents a household of customers. |
| Customers | Represents a customer. |
| DateCanceled | Represents a cancellation date. |

| ATTRIBUTE TYPE | DESCRIPTION |
|------------------------------|--|
| DateDuration | Represents a duration. |
| DateEnded | Represents an end date. |
| DateModified | Represents a modification date. |
| DateStart | Represents a start date. |
| DeletedFlag | <p>Indicates whether a member is or should be deleted (in terms of business functionality.)</p> <p>Note: Analysis Services does not use this attribute type to determine whether a member should be deleted. Instead, this attribute type is intended to be used by client applications for display purposes only.</p> |
| FormattingColor | Represents the color used in formatting. |
| FormattingFont | Represents the font used in formatting. |
| FormattingFontEffects | Represents the font effects used in formatting. |
| FormattingFontSize | Represents the font size used in formatting. |
| FormattingOrder | Represents the order used in formatting. |
| FormattingSubtotal | Represents a subtotal. |
| GeoBoundaryBottom | Represents the bottommost value of a geographic boundary. |
| GeoBoundaryFront | Represents the value at the front of a geographic boundary. |
| GeoBoundaryLeft | Represents the leftmost value of a geographic boundary. |
| GeoBoundaryPolygon | Represents the polygon definition of a geographic boundary. |
| GeoBoundaryRear | Represents the rearmost value of a geographic boundary. |
| GeoBoundaryRight | Represents the rightmost value of a geographic boundary. |
| GeoBoundaryTop | Represents the topmost value of a geographic boundary. |
| GeoCentroidX | Represents an X-axis centroid for a geographic region. |
| GeoCentroidY | Represents a Y-axis centroid for a geographic region. |
| GeoCentroidZ | Represents a Z-axis centroid for a geographic region. |
| ID | Represents an identifier (ID) or key. |
| Image | Represents an image in an undefined graphic format. |

| ATTRIBUTE | TYPE | VALUE | DESCRIPTION |
|---------------------------|------|-------|--|
| ImageBmp | | | Represents an image in bitmap graphic format. |
| ImageGif | | | Represents an image in Graphics Interchange Format (GIF) graphic format. |
| ImageJpg | | | Represents an image in Joint Photographic Experts Group (JPEG) graphic format. |
| ImagePng | | | Represents an image in Portable Network Graphics (PNG) graphic format. |
| ImageTiff | | | Represents an image in Tagged Image File Format (TIFF) graphic format. |
| OrganizationalUnit | | | Represents an organizational unit. |
| OrgTitle | | | Represents an organizational title. |
| PercentOwnership | | | Represents a percent of ownership. |
| PercentVoteRight | | | Represents a percent of voting rights. |
| Person | | | Represents a person. |
| PersonContact | | | Represents contact information for a person. |
| PersonDemographic | | | Represents demographic information for a person. |
| PersonFirstName | | | Represents the first name of a person. |
| PersonFullName | | | Represents the full name of a person. |
| PersonLastName | | | Represents the surname (last name) of a person. |
| PersonMiddleName | | | Represents the middle name of a person. |
| PhysicalColor | | | Represents a color. |
| PhysicalDensity | | | Represents density. |
| PhysicalDepth | | | Represents depth. |
| PhysicalHeight | | | Represents height. |
| PhysicalSize | | | Represents a size. |
| PhysicalVolume | | | Represents volume. |
| PhysicalWeight | | | Represents weight. |
| PhysicalWidth | | | Represents width. |

| ATTRIBUTE TYPE | DESCRIPTION |
|--------------------------|--|
| Point | Represents a point. |
| PostalCode | Represents a postal code. |
| Product | Represents a product. |
| ProductBrand | Represents a product brand. |
| ProductCategory | Represents a product category. |
| ProductGroup | Represents a product group. |
| ProductSKU | Represents a product stock keeping unit (SKU). |
| Project | Represents a project. |
| ProjectCode | Represents a project code. |
| ProjectCompletion | Represents the completion status of a project. |
| ProjectEndDate | Represents a project end date. |
| ProjectName | Represents a project name. |
| ProjectStartDate | Represents a project start date. |
| Promotion | Represents a promotion. |
| QtyRangeHigh | Represents the highest value of a range of quantities. |
| QtyRangeLow | Represents the lowest value of a range of quantities. |
| Quantitative | Represents a quantitative attribute. |
| Rate | Represents a rate. |
| RateType | Represents a rate type. |
| Region | Represents a customer-defined region. |
| Regular | Represents a regular attribute. |
| RelationToParent | Represents a relation to a parent. |
| Representative | Represents a representative. |
| Scenario | Represents a scenario. |
| Sequence | Represents a sequence attribute. |

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|------------------------|---------------------------------|
| ShortCaption | Represents a short caption. |
| StateOrProvince | Represents a state or province. |
| Utility | Represents a utility. |
| Version | Represents a version. |
| WebHtml | Represents HTML content. |
| WebMailAlias | Represents an e-mail alias. |
| WebUrl | Represents a URL address. |
| WebXmlOrXsl | Represents XML or XSL content. |

Account Dimension Attribute Types

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|----------------------|---|
| Account | Represents the parent of an account. This attribute type is typically applied to the parent attribute of an account dimension. |
| AccountName | Represents the name of an account. This attribute type is typically applied to the key attributes of an account dimension. |
| AccountNumber | Represents the number of an account. |
| AccountType | Represents the type of an account. This attribute type identifies the aggregation function of an account member in an account type dimension in the Analysis Services database. |

Currency Dimension Attribute Types

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|----------------------------|--|
| CurrencyDestination | Represents the destination currency of a currency exchange. This attribute type is typically applied to the key attribute of a reporting dimension, for use in currency conversion. For more information about currency conversion, see Currency Conversions (Analysis Services) . |
| CurrencyIsoCode | Represents the International Standards Organization (ISO) code of a currency. For more information about currency conversion, see Currency Conversions (Analysis Services) . |
| CurrencyName | Represents the name of a currency. For more information about currency conversion, see Currency Conversions (Analysis Services) . |

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|-----------------------|--|
| CurrencySource | Represents the source currency of a currency exchange. This attribute type is typically applied to the key attribute of a currency dimension, for use in currency conversion. For more information about currency conversion, see Currency Conversions (Analysis Services) . |

Slowly Changing Dimension Attribute Types

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|----------------------|--|
| ScdEndDate | Represents the effective end date for a member in a slowly changing dimension. |
| ScdOriginalID | Represents the original identifier for a member in a slowly changing dimension. |
| ScdStartDate | Represents the effective start date for a member in a slowly changing dimension. |
| ScdStatus | Represents the effective status of a member in a slowly changing dimension. |

Time Dimension Attribute Types

| ATTRIBUTE TYPE VALUE | DESCRIPTION |
|----------------------------|--|
| Date | Represents a date. This attribute type is typically applied to the key attribute of a time dimension or server time dimension. |
| DayOfHalfYear | Represents the day ordinal of a half-year. |
| DayOfMonth | Represents the day ordinal of a month. |
| DayOfQuarter | Represents the day ordinal of a quarter. |
| DayOfTenDays | Represents the day ordinal of a ten-day period. |
| DayOfTrimester | Represents the day ordinal of a trimester. |
| DayOfWeek | Represents the day ordinal of a week. |
| DayOfYear | Represents the day ordinal of a year. |
| Days | Represents days. |
| FiscalDate | Represents a date in a fiscal calendar. |
| FiscalDayOfHalfYear | Represents the day ordinal of a half-year in a fiscal calendar. |
| FiscalDayOfMonth | Represents the day ordinal of a month in a fiscal calendar. |

| ATTRIBUTE | TYPE | VALUE | DESCRIPTION |
|--------------------------------|------|-------|---|
| FiscalDayOfQuarter | | | Represents the day ordinal of a quarter in a fiscal calendar. |
| FiscalDayOfTrimester | | | Represents the day ordinal of a trimester in a fiscal calendar. |
| FiscalDayOfWeek | | | Represents the day ordinal of a week in a fiscal calendar. |
| FiscalDayOfYear | | | Represents the day ordinal of a year in a fiscal calendar. |
| FiscalHalfYears | | | Represents half-years in a fiscal calendar. |
| FiscalHalfYearOfYear | | | Represents the half-year ordinal of a year in a fiscal calendar. |
| FiscalMonths | | | Represents months in a fiscal calendar. |
| FiscalMonthOfHalfYear | | | Represents the month ordinal of a half-year in a fiscal calendar. |
| FiscalMonthOfQuarter | | | Represents the month ordinal of a quarter in a fiscal calendar. |
| FiscalMonthOfTrimester | | | Represents the month ordinal of a trimester in a fiscal calendar. |
| FiscalMonthOfYear | | | Represents the month ordinal of a year in a fiscal calendar. |
| FiscalQuarters | | | Represents quarters in a fiscal calendar. |
| FiscalQuarterOfHalfYear | | | Represents the quarter ordinal of a half-year in a fiscal calendar. |
| FiscalQuarterOfYear | | | Represents the quarter ordinal of a year in a fiscal calendar. |
| FiscalTrimesters | | | Represents trimesters in a fiscal calendar. |
| FiscalTrimesterOfYear | | | Represents the trimester ordinal of a year in a fiscal calendar. |
| FiscalWeeks | | | Represents weeks in a fiscal calendar. |
| FiscalWeekOfHalfYear | | | Represents the week ordinal of a half-year in a fiscal calendar. |
| FiscalWeekOfMonth | | | Represents the week ordinal of a month in a fiscal calendar. |
| FiscalWeekOfQuarter | | | Represents the week ordinal of a quarter in a fiscal calendar. |
| FiscalWeekOfTrimester | | | Represents the week ordinal of a trimester in a fiscal calendar. |
| FiscalWeekOfYear | | | Represents the week ordinal of a year in a fiscal calendar. |
| FiscalYears | | | Represents years in a fiscal calendar. |
| HalfYears | | | Represents half-years. |

| ATTRIBUTE | TYPE | VALUE | DESCRIPTION |
|------------------------------------|------|-------|---|
| HalfYearOfYear | | | Represents the half-year ordinal of a year. |
| Hours | | | Represents hours. |
| IsHoliday | | | Indicates whether a date is a holiday. |
| ISO8601Date | | | Represents a date in an ISO 8601 calendar. |
| ISO8601DayOfWeek | | | Represents the day ordinal of a week in an ISO 8601 calendar. |
| ISO8601DayOfYear | | | Represents the day ordinal of a year in an ISO 8601 calendar. |
| ISO8601Weeks | | | Represents weeks in an ISO 8601 calendar. |
| ISO8601WeekOfYear | | | Represents the week ordinal of a year in an ISO 8601 calendar. |
| ISO8601Years | | | Represents years in an ISO 8601 calendar. |
| IsPeakDay | | | Indicates whether a date is a peak day. |
| IsWeekDay | | | Indicates whether a date is a weekday. |
| IsWorkingDay | | | Indicates whether a date is a working day. |
| ManufacturingDate | | | Represents a date in a manufacturing calendar. |
| ManufacturingDayOfHalfYear | | | Represents the day ordinal of a half-year in a manufacturing calendar. |
| ManufacturingDayOfMonth | | | Represents the day ordinal of a month in a manufacturing calendar. |
| ManufacturingDayOfQuarter | | | Represents the day ordinal of a quarter in a manufacturing calendar. |
| ManufacturingDayOfTrimester | | | Represents the day ordinal of a trimester in a manufacturing calendar. |
| ManufacturingDayOfWeek | | | Represents the day ordinal of a week in a manufacturing calendar. |
| ManufacturingDayOfYear | | | Represents the day ordinal of a year in a manufacturing calendar. |
| ManufacturingHalfYears | | | Represents half-years in a manufacturing calendar. |
| ManufacturingHalfYearOfYear | | | Represents the half-year ordinal of a year in a manufacturing calendar. |
| ManufacturingMonths | | | Represents months in a manufacturing calendar. |

| ATTRIBUTE | TYPE | VALUE | DESCRIPTION |
|---------------------------------------|------|-------|--|
| ManufacturingMonthOfHalfYear | | | Represents the month ordinal of a half-year in a manufacturing calendar. |
| ManufacturingMonthOfQuarter | | | Represents the month ordinal of a quarter in a manufacturing calendar. |
| ManufacturingMonthOfTrimester | | | Represents the month ordinal of a trimester in a manufacturing calendar. |
| ManufacturingMonthOfYear | | | Represents the month ordinal of a year in a manufacturing calendar. |
| ManufacturingQuarters | | | Represents quarters in a manufacturing calendar. |
| ManufacturingQuarterOfHalfYear | | | Represents the quarter ordinal of a half-year in a manufacturing calendar. |
| ManufacturingQuarterOfYear | | | Represents the quarter ordinal of a year in a manufacturing calendar. |
| ManufacturingWeeks | | | Represents weeks in a manufacturing calendar. |
| ManufacturingWeekOfHalfYear | | | Represents the week ordinal of a half-year in a manufacturing calendar. |
| ManufacturingWeekOfMonth | | | Represents the week ordinal of a month in a manufacturing calendar. |
| ManufacturingWeekOfQuarter | | | Represents the week ordinal of a quarter in a manufacturing calendar. |
| ManufacturingWeekOfTrimester | | | Represents the week ordinal of a trimester in a manufacturing calendar. |
| ManufacturingWeekOfYear | | | Represents the week ordinal of a year in a manufacturing calendar. |
| ManufacturingYears | | | Represents years in a manufacturing calendar. |
| Minutes | | | Represents minutes. |
| Months | | | Represents months. |
| MonthOfHalfYear | | | Represents the month ordinal of a half-year. |
| MonthOfQuarter | | | Represents the month ordinal of a quarter. |
| MonthOfTrimester | | | Represents the month ordinal of a trimester. |
| MonthOfYear | | | Represents the month ordinal of a year. |
| Quarters | | | Represents quarters. |

| ATTRIBUTE | TYPE | VALUE | DESCRIPTION |
|-----------------------------------|------|-------|--|
| QuarterOfHalfYear | | | Represents the quarter ordinal of a half-year. |
| QuarterOfYear | | | Represents the quarter ordinal of a year. |
| ReportingDate | | | Represents a date in a reporting calendar. |
| ReportingDayOfHalfYear | | | Represents the day ordinal of a half-year in a reporting calendar. |
| ReportingDayOfMonth | | | Represents the day ordinal of a month in a reporting calendar. |
| ReportingDayOfQuarter | | | Represents the day ordinal of a quarter in a reporting calendar. |
| ReportingDayOfTrimester | | | Represents the day ordinal of a trimester in a reporting calendar. |
| ReportingDayOfWeek | | | Represents the day ordinal of a week in a reporting calendar. |
| ReportingDayOfYear | | | Represents the day ordinal of a year in a reporting calendar. |
| ReportingHalfYears | | | Represents half-years in a reporting calendar. |
| ReportingHalfYearOfYear | | | Represents the half-year ordinal of a year in a reporting calendar. |
| ReportingMonths | | | Represents months in a reporting calendar. |
| ReportingMonthOfHalfYear | | | Represents the month ordinal of a half-year in a reporting calendar. |
| ReportingMonthOfQuarter | | | Represents the month ordinal of a quarter in a reporting calendar. |
| ReportingMonthOfTrimester | | | Represents the month ordinal of a trimester in a reporting calendar. |
| ReportingMonthOfYear | | | Represents the month ordinal of a year in a reporting calendar. |
| ReportingQuarters | | | Represents quarters in a reporting calendar. |
| ReportingQuarterOfHalfYear | | | Represents the quarter ordinal of a half-year in a reporting calendar. |
| ReportingQuarterOfYear | | | Represents the quarter ordinal of a year in a reporting calendar. |
| ReportingTrimesters | | | Represents trimesters in a reporting calendar. |
| ReportingTrimesterOfYear | | | Represents the trimester ordinal of a year in a reporting calendar. |

| ATTRIBUTE TYPE | DESCRIPTION |
|---------------------------------|---|
| ReportingWeeks | Represents weeks in a reporting calendar. |
| ReportingWeekOfHalfYear | Represents the week ordinal of a half-year in a reporting calendar. |
| ReportingWeekOfMonth | Represents the week ordinal of a month in a reporting calendar. |
| ReportingWeekOfQuarter | Represents the week ordinal of a quarter in a reporting calendar. |
| ReportingWeekOfTrimester | Represents the week ordinal of a trimester in a reporting calendar. |
| ReportingWeekOfYear | Represents the week ordinal of a year in a reporting calendar. |
| ReportingYears | Represents years in a reporting calendar. |
| Seconds | Represents seconds. |
| TenDayOfHalfYear | Represents the ten-day period ordinal of a half-year. |
| TenDayOfMonth | Represents the ten-day period ordinal of a month. |
| TenDayOfQuarter | Represents the ten-day period ordinal of a quarter. |
| TenDayOfTrimester | Represents the ten-day period ordinal of a trimester. |
| TenDayOfYear | Represents the ten-day period ordinal of a year. |
| TenDays | Represents ten-day periods. |
| Trimesters | Represents trimesters. |
| TrimesterOfYear | Represents the trimester ordinal of a year. |
| UndefinedTime | Represents an undefined time period. |
| WeekOfYear | Represents the week ordinal of a year. |
| Weeks | Represents weeks. |
| WinterSummerSeason | Indicates whether the date is part of the winter/summer season. |
| Years | Represents years. |

Attribute Properties - Group Attribute Members

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A member group is a system-generated collection of consecutive dimension members. In Microsoft SQL Server Analysis Services, members of an attribute can be grouped into a number of member groups through a process called discretization. A level in a hierarchy contains either member groups or members, but not both. When business users browse a level that contains member groups, they see the names and cell values of the member groups. The members generated by Analysis Services to support member groups are called grouping members, and look like ordinary members.

The **DiscretizationMethod** property on an attribute controls how the members are grouped.

| DISCRETIZATIONMETHOD SETTING | DESCRIPTION |
|------------------------------|--|
| None | Displays the members. |
| Automatic | Selects the method that best represents the data: either the EqualAreas method or the Clusters method. |
| EqualAreas | Tries to divide the members in the attribute into groups that contain an equal number of members. |
| Clusters | Tries to divide the members in the attribute into groups by sampling the training data, initializing to a number of random points, and running several iterations of the Expectation-Maximization (EM) clustering algorithm.

This method is useful because it works on any distribution curve, but is more expensive in terms of processing time. |

The **DiscretizationNumber** property on attributes specifies the number of groups to display. If the property is set to the default value of 0, Analysis Services determines the number of groups by either sampling or reading the data, depending on the setting of the **DiscretizationMethod** property.

The sort order of members in the member groups is controlled by using the **OrderBy** property of the attribute. Based on this sort order, the members in a member group are ordered consecutively.

A common use for member groups is to drill down from a level with few members to a level with many members. To enable users to drill down between levels, change the **DiscretizationMethod** property on the attribute for the level that contains numerous members from **None** to one of the discretization methods described in the previous table. For example, a Client dimension contains a Client Name attribute hierarchy with 500,000 members. You can rename this attribute Client Groups and set the **DiscretizationMethod** property to **Automatic** to display member groups on the attribute hierarchy member level.

To drill down to individual clients in each group, you can create another Client Name attribute hierarchy bound to the same table column. Then, create a new user hierarchy based on the two attributes. The top level would be based on the Client Groups attribute and the lower level would be based on the Client Name attribute. The **IsAggregatable** property would be **True** on both attributes. The user could then expand the (All) level on the hierarchy to view the group members, and expand the group members to view the leaf members of the hierarchy. To hide either group or client level, you could set the **AttributeHierarchyVisible** property to **False** on the corresponding attribute.

Naming Template

Member group names are generated automatically when the member groups are created. Unless you specify a naming template, the default naming template is used. You can change this method of naming by specifying a naming template in the **Format** option for the **NameColumn** property of an attribute. Different naming templates can be redefined for every language specified in the **Translations** collection of the column binding that was used for the **NameColumn** property of the attribute.

The **Format** setting uses the following string expression to define the naming template:

```
<Naming template> ::= <First definition> [<Intermediate definition>;<Last definition>]  
  
<First definition> ::= <Name expression>  
  
<Intermediate definition> ::= <Name expression>  
  
<Last definition> ::= <Name expression>
```

The `<First definition>` parameter applies only to the first or only member group generated by the discretization method. If the optional parameters `<Intermediate definition>` and `<Last definition>` are not provided, the `<First definition>` parameter is used for all measure groups generated for that attribute.

The `<Last definition>` parameter applies only to the last member group generated by the discretization method.

The `<Intermediate bucket name>` parameter applies to every member group other than the first or last member group generated by the discretization method. If two or fewer member groups are generated, this parameter is ignored.

The `<Bucket name>` parameter is a string expression that can incorporate a set of variables to represent member or member group information as part of the name of the member group:

| VARIABLE | DESCRIPTION |
|---|---|
| <code>%{First bucket member}</code> | The member name of the first member to be included in the current member group. |
| <code>%{Last bucket member}</code> | The member name of the last member to be included in the current member group. |
| <code>%{Previous bucket last member}</code> | The member name of the last member assigned to the previous member group. |
| <code>%{Next bucket first member}</code> | The member name of the first member to be assigned to the next member group. |
| <code>%{Bucket Min}</code> | The minimum value of the members to be assigned to the current member group. |
| <code>%{Bucket Max}</code> | The maximum value of the members to be assigned to the current member group. |
| <code>%{Previous Bucket Max}</code> | The maximum value of the members to be assigned to the previous member group. |
| <code>%{Next Bucket Min}</code> | The minimum value of the members to be assigned to the next member group. |

The default naming template is "`%{First bucket member} - %{Last bucket member}`", to provide compatibility with earlier versions of Analysis Services.

NOTE

To include a semicolon (:) as a literal character in the naming template, prefix it with the percent (%) character.

Example

The following string expression could be used to classify the Yearly Income attribute of the Customer dimension in the Adventure Works DW Multidimensional 2012 sample Analysis Services database, where the Yearly Income attribute uses member grouping:

"Less than %{Next Bucket Min};Between %{First bucket member} and %{Last bucket member};Greater than %{Previous Bucket Max}"

Adding New Members to Existing Member Groups

If new members are added to the dimension, they are assigned to the appropriate member groups by comparing the value of the member against the current member group layout.

If a member is inserted between the last member of the previous member group and the first member of the next member group, the new member becomes the last member of the previous member group.

Updating a Dimension with Discretized Attributes

When you process a dimension, a discretized attribute is rediscretized only with a full update (ProcessFull). To rediscretize an attribute, you must perform a full update of the dimension. If the dimension table of a discretized attribute is updated and you process the dimension with an incremental update (ProcessAdd), the discretized attribute is not rediscretized. The names and children of the new buckets remain the same. For more information about processing dimensions, see [Processing Analysis Services Objects](#).

Usage Limitations

- You cannot create member groups in the topmost or bottommost level of a hierarchy. However, if you need to do this, you can add a level in such a way that the level in which you want to create member groups is no longer the top or bottom level. You can hide the added level by setting its **Visible** property to **False**.
- You cannot create member groups in two consecutive levels of a hierarchy.
- Member groups are not supported for dimensions that use the ROLAP storage mode.
- If the dimension table of a dimension that contains member groups is updated, and the dimension is subsequently fully processed, a new set of member groups is generated. The names and children of the new member groups may be different from the old member groups.

[Attributes and Attribute Hierarchies](#)

Attribute Properties - Define Custom Member Formulas

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can define a Multidimensional Expressions (MDX) expression, called a custom member formula, to supply the values for the members of a specified attribute. A column in a table from a data source view provides, for each member in an attribute, the expression used to supply the value for that member.

Custom member formulas determine the cell values that are associated with members and override the aggregate functions of measures. Custom member formulas are written in MDX. Each custom member formula applies to a single member. Custom member formulas are stored in the dimension table or in another table that has a foreign key relationship with the dimension table.

The **CustomRollupColumn** property on an attribute specifies the column that contains custom member formulas for members of the attribute. If a row in the column is empty, the cell value for the member is returned normally. If the formula in the column is not valid, a run-time error occurs whenever a cell value that uses the member is retrieved.

Before you can specify custom member formulas for an attribute, make sure that the dimension table that contains the attribute, or a directly related table, has a string column to store the custom member formulas. If this is the case, you can either set the **CustomRollupColumn** property on an attribute manually or use the Set Custom Member Formula enhancement of the Business Intelligence Wizard to enable a custom member formula on an attribute. For more information about how to use this enhancement, see [Set Custom Member Formulas for Attributes in a Dimension](#).

Evaluating Custom Member Formulas

Custom member formulas differ from calculated members. Custom member formulas apply to members that exist in dimension tables, and only provide the value of the member. In contrast, calculated members are not stored in dimension tables, and calculated member expressions define both data and metadata for additional members included in a dimension or hierarchy.

Custom member formulas override the aggregate functions associated with measures. For example, before a custom member formula is specified, a measure using the **Sum** aggregate function has the following values for the following members of the Time dimension:

- 2003: 2100
 - Quarter 1: 700
 - Quarter 2: 500
 - Quarter 3: 100
 - Quarter 4: 800
- 2004: 1500
 - Quarter 1: 600
 - Quarter 2: 200

- Quarter 3: 300
- Quarter 4: 400

With a custom member formula, the value of the member is instead supplied by the custom rollup formula. For example, the following custom member formula can be used to supply the value for the Quarter 4 child member of the 2004 member in the Time dimension as 450.

```
Time.[Quarter 3] * 1.5
```

Custom member formulas are stored in a column of the dimension table. You enable custom rollup formulas by setting the **CustomRollupColumn** property on an attribute.

To apply a single MDX expression to all members of an attribute, create a named calculation on the dimension table that returns an MDX expression as a literal string. Then, specify the named calculation with the **CustomRollupColumn** property setting on the attribute that you want to configure. A named calculation is a column in a data source view table that returns row values defined by a SQL expression. For more information about constructing named calculations, see [Define Named Calculations in a Data Source View \(Analysis Services\)](#)

NOTE

To apply an MDX expression to members of a particular level instead of to members of all levels based on a particular attribute, you can define the expression as an MDX script on the level. For more information, see [MDX Scripting Fundamentals \(Analysis Services\)](#).

If you use both calculated members and custom rollup formulas for members of an attribute, you should be aware of the order of evaluation. Calculated members are resolved before custom rollup formulas are resolved.

[Attributes and Attribute Hierarchies](#)

[Set Custom Member Formulas for Attributes in a Dimension](#)

Attribute Properties - Define a Default Member

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The default member of an attribute hierarchy is used to evaluate expressions when an attribute hierarchy is not included in a query. The default member is ignored whenever a query includes an attribute hierarchy or user hierarchy that contains the attribute that sources the attribute hierarchy. This is because the member specified in the query is used.

The default member for an attribute hierarchy is set by specifying an attribute member as the **DefaultMember** property value for the attribute hierarchy. You can set this property on the Dimension Structure tab in Dimension Designer, or in the cube's calculation script on the Calculation tab in Cube Designer in Visual Studio with Analysis Services projects. You can also specify the **DefaultMember** property for a security role (overriding the default member set on the dimension) on the Dimension Data tab when defining dimension security. To avoid name resolution problems, define the default member in the cube's MDX script in the following situations: if the cube refers to a database dimension more than once, if the dimension in the cube has a different name than the dimension in the database, or if you want to have different default members in different cubes.

The default member on an attribute is used to evaluate expressions when an attribute is not included in a query. The default member for an attribute is specified by the **DefaultMember** property on the attribute. Whenever a hierarchy from a dimension is included in a query, all the default members from attributes corresponding to levels in the hierarchy are ignored. If no hierarchy of a dimension is included in a query, default members are used for all the attributes in the dimension.

Resolving the Default Member When No Default Member is Specified

If no default member is specified for an attribute hierarchy, and the attribute hierarchy is aggregatable (the **IsAggregatable** property on the attribute is set to **True**), the (All) member is the default member. If no default member is specified and the attribute hierarchy is not aggregatable (the **IsAggregatable** property on the attribute is set to **False**), a default member is selected from the attribute hierarchy's top level.

Specifying the Default Member

Every attribute in a dimension in Microsoft SQL Server Analysis Services has a default member, which you can specify by using the **DefaultMember** property for an attribute. This setting is used to evaluate expressions if an attribute is not included in a query. If a query specifies a hierarchy in a dimension, the default members for the attributes in the hierarchy are ignored. If a query does not specify a hierarchy in a dimension, the **DefaultMember** settings for dimension attributes take effect.

If the **DefaultMember** setting for an attribute is blank and its **IsAggregatable** property is set to **True**, the default member is the All member. If the **IsAggregatable** property is set to **False**, the default member is the first member of the first visible level.

The **DefaultMember** setting for an attribute applies to every hierarchy in which the attribute participates. You cannot use different settings for different hierarchies in a dimension. For example, if the [1998] member is the default member for a [Year] attribute, this setting applies to every hierarchy in the dimension. The **DefaultMember** setting in this case cannot be [1998] in one hierarchy and [1997] in a different hierarchy.

If you define a default member for a particular level in a hierarchy that does not aggregate naturally, you must define default members in all levels above that level in the hierarchy. For example, in the hierarchy All-Countries-

Climate, you cannot define a default member for Climate unless you define a default member for Countries. Failing to do so creates query-time errors.

When levels in a hierarchy aggregate naturally, you can define a default member for any attribute in the hierarchy without regard to other attributes in the hierarchy. For example, in the hierarchy Country-Province-City, you can define a default member for City such as [City].[Montreal] without defining the default member for State or for Country.

[Configure the \(All\) Level for Attribute Hierarchies](#)

Attribute Properties – View Attributes in Dimension Designer

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Attributes are created on dimension objects. You can view and configure attributes by using Dimension Designer in Microsoft SQL Server Analysis Services. The **Attributes** pane of the **Dimension Structure** tab of Dimension Designer lists the attributes that are in a dimension. Use this pane to add, remove, or configure attributes. You can also select attributes to use as a level in a new hierarchy or to add as a level in an existing hierarchy.

To view the attributes in a dimension, open Dimension Designer for the dimension. The **Attributes** pane of the **Dimension Structure** tab of the designer shows the attributes that are in the dimension. You can switch between a list, tree, or grid view by pointing to **Show Attributes in** on the **Dimension** menu of Visual Studio with Analysis Services projects and then clicking one of the following commands:

1. Show Attributes in a **List**. Displays the attributes in list format. Right-click an attribute to delete it from the list, to rename the attribute, or to change the usage of the attribute. Use this view for building hierarchies. Attribute information and member properties are not visible.
2. Show Attributes in a **Tree**. Display the attributes in tree format, with the dimension as the top-level node in the tree. Expand an attribute to view attribute relationships for it or to create a new attribute relationship, by performing the following actions:
 - Click the dimension, an attribute, or a member property to view its properties in the **Properties** window.
 - Right-click an attribute or a member property to delete it from the list, to rename it, or to change its usage.

Use this view for viewing and creating member properties. You can also use this view to build hierarchies.

3. Show Attributes in a **Grid**. Display the attributes in grid format. The grid displays the following columns:
 - **Name** shows the value of the **Name** property. Type a different name to change the setting.
 - **Usage** specifies whether this is a Regular, Key, Parent, or AccountType attribute. Click a value in this column to select a different setting.
 - **Type** specifies the business intelligence category for the attribute. Click this cell to select a different setting.
 - **Key Column** shows the OLE DB data type for the **KeyColumn** property on the attribute. This column cannot be changed.
 - **Name Column** indicates whether the **NameColumn** property setting on the attribute is the same column as the setting for the **KeyColumn** property. This column cannot be changed.

Click any row in the grid to view properties for that attribute.

Use this view for creating and configuring attributes.

In Visual Studio with Analysis Services projects, the icons shown in the following table mark attributes according to their usage.

| ICON | ATTRIBUTE USAGE |
|---|------------------------|
|  | Regular or AccountType |
|  | Key |
|  | Parent |

[Dimension Attribute Properties Reference](#)

Attribute Properties - Define a New Attribute Automatically

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can create a new attribute in a dimension by using drag-and-drop editing in the Dimension Designer.

To create a new attribute automatically

1. In Dimension Designer, open the dimension in which you want to create the attribute.
2. On the **Dimension Structure** tab, in the **Data Source View** pane, in the table to which you want to bind the attribute, select the column, and then drag the column to the **Attributes** pane.

Analysis Services creates the new attribute that has the same name as the column to which it is bound. If there are multiple attributes that use the same column, Analysis Services appends a number to the attribute name.

[Dimensions in Multidimensional Models](#)

[Dimension Attribute Properties Reference](#)

View Attributes in Dimension Designer

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

This procedure describes how to change the way that attributes are displayed in the Dimension Designer.

To change the format of the Attributes pane in Dimension Designer

1. In Dimension Designer, open the dimension that contains the attributes you want to work with, and click the Dimension Structure tab.
2. Click anywhere in the **Attributes** pane to set the focus to the **Attributes** pane.
3. Click the **Dimension** menu, or, right-click the **Attributes** pane.
4. Point to **Show Attributes In**, and then click **Tree**, **Grid**, or **List**.

Attribute Properties - Modify the KeyColumn Property

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can modify the **KeyColumns** property of an attribute. For example, you might want to specify a composite key instead of a single key as the key for the attribute.

To modify the KeyColumns property of an attribute

1. In Visual Studio with Analysis Services projects, open the project in which you want to modify the **KeyColumns** property.
2. Open Dimension Designer by doing one of the following procedures:
 - In **Solution Explorer**, right-click the dimension in the **Dimensions** folder, and then either click **Open** or **View Designer**.
 - or-
 - In Cube Designer, on the **Cube Structure** tab, expand the cube dimension in the **Dimensions** pane and click **Edit <dimension>**.
3. On the **Dimension Structure** tab, in the **Attributes** pane, click the attribute whose **KeyColumns** property you want to modify.
4. In the **Properties** window, click the value for the **KeyColumns** property.
5. Click the browse (...) button that appears in the value cell of the property box.

The **Key Columns** dialog box opens.

6. To remove an existing key column, in the **Key Columns** list, select the column, and then click the < button.
7. To add a key column, in the **Available Columns** list, select the column, and then click the > button.

NOTE

If you define multiple key columns, the order in which those columns appear in the **Key Columns** list affects the display order. For example, a month attribute has two key columns: month and year. If the year column appears in the list before the month column, Analysis Services will sort by year and then by month. If the month column appears before the year column, Analysis Services will sort by month and then by year.

8. To change the order of key columns, select a column, and then click the **Up** or **Down** button.

Attribute Properties - Bind an Attribute to a Key Column

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

This procedure describes how to change the setting for the **Name** property of an attribute in a dimension.

To bind an attribute to a key column

1. In Dimension Designer, open the dimension that contains the attribute you want to rename.
2. In the **Attributes** pane of the Dimension Builder view, change the display format to either **Tree** or **List**. For more information about how to change the format of the Attributes pane, see [View Attributes in a Tree, List or Grid in Dimension Designer](#).
3. Right-click the attribute you want to configure, and then click **Rename**.
4. Type the new name.

NOTE

You can also set the **Name** property of a selected attribute in the **Properties** window of Visual Studio with Analysis Services projects.

Attribute Properties - Bind an Attribute to a Name Column

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

This procedure describes how to bind an attribute to a name column manually by using the **Attributes** pane in the Dimension Designer and by using the **Object Binding** dialog box.

To bind an attribute to a name column

1. In Dimension Designer, open the dimension in which you want to create the attribute.
2. On the **Dimension Structure** tab, in the **Attributes** pane, right-click the attribute that you want to configure, and then click **Properties**.
3. In the **Properties** window, locate the **NameColumn** property, and then select **(new)**.
4. In the **Object Binding** dialog box, for **Binding type**, select **Column binding**.
5. In the **Source column** list, select the column to which the attribute will be bound, and then click **OK**.

Attribute Properties – Set Usage Property

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can set the usage for an attribute by using the **Dimension Structure** view in Dimension Designer, which is accessed from Visual Studio with Analysis Services projects.

When you set usage for an attribute, your changes do not take effect until you process the dimension. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To set usage for an attribute

1. In Solution Explorer, right-click a dimension, and click **Open**.

The **Dimension Structure** view opens by default.

2. In **Attributes**, right-click the attribute for which you want to set usage, point to **Set Attribute Usage**, and then click one of the following options:

- **Regular**
- **Key**
- **Parent**

[Add an Attribute to a Dimension](#)

Attribute Properties – Define Member Groups

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

If an attribute has a large number of members, you can choose to group those members into buckets, reducing the number of members that users see when they browse the data in a hierarchy. You can also determine the number of buckets in which the members are groups and set a naming scheme for the buckets. For more information, see [Group Attribute Members \(Discretization\)](#).

You group members by setting the **DiscretizationMethod** property, which is accessed through the **Properties** window in Visual Studio with Analysis Services projects.

When you create member groups, your changes are not available to users until you process the dimension. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To create member groups

1. Open the dimension that you want to work with. The **Dimension Structure** tab opens by default.
2. In **Attributes**, right-click the attribute whose members you want to group, and then click **Properties**.
3. From the drop-down list next to **DiscretizationMethod**, select a method by which to group the members.
For more information about **DiscretizationMethod** settings, see [Group Attribute Members \(Discretization\)](#).

Parent-Child Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A parent-child hierarchy is a hierarchy in a standard dimension that contains a parent attribute. A parent attribute describes a *self-referencing relationship*, or *self-join*, within a dimension main table. Parent-child hierarchies are constructed from a single parent attribute. Only one level is assigned to a parent-child hierarchy, because the levels present in the hierarchy are drawn from the parent-child relationships between members associated with the parent attribute. The position of a member in a parent-child hierarchy is determined by the **KeyColumns** and **RootMemberId** properties of the parent attribute, whereas the position of a member in a level is determined by the **OrderBy** property of the parent attribute. For more information about attribute properties, see [Attributes and Attribute Hierarchies](#).

Because of parent-child relationships between levels in a parent-child hierarchy, some nonleaf members can also have data derived from underlying data sources, in addition to data aggregated from child members.

Dimension Schema

The dimension schema of a parent-child hierarchy depends on a self-referencing relationship present on the dimension main table. For example, the following diagram illustrates the **DimOrganization** dimension main table in the **AdventureWorksDW2012** sample database.

| DimOrganization | |
|-----------------|---|
| PK | OrganizationKey |
| FK2 | ParentOrganizationKey
PercentageOfOwnership
OrganizationName
ParentOrganizationName
CurrencyKey |
| FK1 | |

In this dimension table, the **ParentOrganizationKey** column has a foreign key relationship with the **OrganizationKey** primary key column. In other words, each record in this table can be related through a parent-child relationship with another record in the table. This kind of self-join is generally used to represent organization entity data, such as the management structure of employees in a department.

Hierarchies and Levels

Dimensions that do not have a parent-child relationship construct hierarchies by grouping and ordering attributes. These dimensions derive the level names for their hierarchies from the attribute names.

However, parent-child dimensions construct parent-child hierarchies by examining the data that the dimension main table contains, and then evaluating the parent-child relationships between the records in the table. For more information about parent-child hierarchies, see [User Hierarchies](#).

Parent-child hierarchies do not derive the names for the levels in a parent-child hierarchy from the attributes that are used to create the hierarchy. Instead, these dimensions create level names automatically by using a naming template—a string expression you can specify at the level of the parent attribute that controls how the attribute generates the attribute hierarchy. For more information about how to set the naming template for a parent attribute, see [Attributes and Attribute Hierarchies](#).

Data Members

Typically, leaf members in a dimension contain data derived directly from underlying data sources, whereas nonleaf members contain data derived from aggregations performed on child members.

However, parent-child hierarchies might have some nonleaf members whose data is derived from underlying data sources, in addition to data aggregated from child members. For these nonleaf members in a parent-child hierarchy, special system-generated child members can be created that contain the underlying fact table data. Referred to as *data members*, these special child members contain a value that is directly associated with a nonleaf member and is independent of the summary value calculated from the descendants of the nonleaf member. For more information about data members, see [Attributes in Parent-Child Hierarchies](#).

See Also

[Attributes in Parent-Child Hierarchies](#)

[Database Dimension Properties](#)

Parent-Child Dimension Attributes

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, a general assumption is usually made about the content of members in a dimension. Leaf members contain data derived directly from underlying data sources; nonleaf members contain data derived from aggregations performed on child members.

In a parent-child hierarchy, however, some nonleaf members may also have data derived from underlying data sources, in addition to data aggregated from child members. For these nonleaf members in a parent-child hierarchy, special system-generated child members are created that contain the underlying fact table data. Referred to as *data members*, they contain a value directly associated with a nonleaf member that is independent of the summary value calculated from the descendants of the nonleaf member.

Data members are available only to dimensions with parent-child hierarchies, and are visible only if allowed by the parent attribute. You can use Dimension Designer to control the visibility of data members. To expose data members, set the **MembersWithData** property for the parent attribute to **NonLeafDataVisible**. To hide data members contained by the parent attribute, set the **MembersWithData** property on the parent attribute to **NonLeafDataHidden**.

This setting does not override the normal aggregation behavior for nonleaf members; the data member is always included as a child member for the purposes of aggregation. However, a custom rollup formula can be used to override the normal aggregation behavior. The Multidimensional Expressions (MDX) **DataMember** function gives you the ability to access the value of the associated data member regardless of the value of the **MembersWithData** property.

The **MembersWithDataCaption** property of the parent attribute provides Analysis Services with the naming template used to generate member names for data members.

Using Data Members

Data members are useful when aggregating measures along organizational dimensions that have parent-child hierarchies. For example, the following diagram shows a dimension that has three levels, representing the gross sales volume of products. The first level shows the gross sales volume for all salespersons. The second level contains the gross sales volume for all sales staff grouped by sales manager, and the third level contains the gross sales volume for all sales staff grouped by salesperson.

Ordinarily, the value of the Sales Manager 1 member would be derived by aggregating the values of the Salesperson 1 and Salesperson 2 members. However, because Sales Manager 1 also can sell products, that member may also contain data derived from the fact table, because there may be gross sales associated with Sales Manager 1.

Moreover, the individual commissions for each sales staff member can vary. In this case, two different scales are used to compute commissions for the individual gross sales of the sales managers, as opposed to the total of gross sales generated by their salespersons. Therefore, it is important to be able to access the underlying fact

table data for nonleaf members. The MDX **DataMember** function can be used to retrieve the individual gross sales volume of the Sales Manager 1 member, and a custom rollup expression can be used to exclude the data member from the aggregated value of the Sales Manager 1 member, providing the gross sales volume of the salespersons associated with that member.

[Parent-Child Dimensions](#)

Parent-Child Dimension Attributes - Custom Rollup Operators

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Custom rollup operators provide a simple way to control how member values are rolled up into parent values in a parent-child hierarchy. In a dimension containing a parent-child relationship, you specify a column that contains unary operators that specify rollup for all noncalculated members of the parent attribute. The unary operator is applied to members whenever the values of the parent members are evaluated.

The unary operators are stored in column defined by the **UnaryOperatorColumn** property of the parent attribute, and they are applied to each member of the attribute. The column specified by this property can reside either in the dimension table or in a table related to the dimension table by a foreign key in the dimension table.

Custom rollup operators provide functionality similar to, but more simplified than, custom member formulas. A custom member formula uses Multidimensional Expressions (MDX) expressions to determine how the members are rolled up. In contrast, a custom rollup operator uses a simple unary operator to determine how the value of a member affects the parent. Custom member formulas of the preceding level in a dimension override a level's custom rollup operator.

Custom Rollup Precedence

In terms of precedence, the custom rollup operators of the source attribute for a level in a hierarchy override the custom member formulas of the previous level. However, the custom member formulas of the preceding level override the custom rollup operators of a level.

Parent-Child Dimension Attributes - Unary Operators

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In a dimension that contains a parent-child relationship in Microsoft SQL Server Analysis Services, you specify a unary (or custom rollup) operator column that determines the custom rollup for all noncalculated members of the parent attribute. The unary operator is applied to members whenever the values of the parent members are evaluated. The **UnaryOperatorColumn** on a parent attribute (**Usage**=Parent) specifies the column of a table in the data source view that contains unary operators. Values for the custom rollup operators that are stored in this column are applied to each member of the attribute.

You can create and specify a named calculation on a dimension table in the data source view as a unary operator column. The simplest expression, such as '+', returns the same operator for all members. But you can use any expression as long as it returns an operator for every member.

You can change the **UnaryOperatorColumn** property setting manually on a parent attribute or use the Define Custom Aggregation enhancement of the Business Intelligence Wizard to replace the default aggregation that is associated with members of a dimension. For more information about how to use the Business Intelligence Wizard to perform this configuration, see [Add a Custom Aggregation to a Dimension](#).

The default setting for the **UnaryOperatorColumn** property on a parent attribute is (none), which disables the custom rollup operators. The following table lists the unary operators and describes how they behave when they are applied to a level.

| UNARY OPERATOR | DESCRIPTION |
|----------------|---|
| +(plus sign) | The value of the member is added to the aggregate value of the sibling members that occur before the member. This operator is the default operator if no unary operator column is defined for an attribute. |
| -(minus sign) | The value of the member is subtracted from the aggregate value of the sibling members that occur before the member. |
| *(asterisk) | The value of the member is multiplied by the aggregate value of the sibling members that occur before the member. |
| /(slash mark) | The value of the member is divided by the aggregate value of the sibling members that occur before the member. |
| ~(tilde) | The value of the member is ignored. |

Blank values and any other values not found in the table are treated the same as the plus sign (+) unary operator. There is no operator precedence, so the order of members as stored in the unary operator column determines the order of evaluation. To change the order of evaluation, create a new attribute, set its **Type** property to **Sequence**, and then assign sequence numbers that correspond to the order of evaluation in its **Source Column** property. You must also order members of the attribute by that attribute. For information about how to use the Business Intelligence Wizard to order members of an attribute, see [Define the Ordering for a Dimension](#).

You can use the **UnaryOperatorColumn** property to specify a named calculation that returns a unary operator as a literal character for all members of the attribute. This could be as simple as typing a literal character such as `'*'`

in the named calculation. This would replace the default operator, the plus sign (+), with the multiplication operator, the asterisk (*), for all members of the attribute. For more information, see [Define Named Calculations in a Data Source View \(Analysis Services\)](#).

In the **Browser** tab of Dimension Designer, you can view the unary operators next to each member in a hierarchy. You can also change the unary operators when you work with a write-enabled dimension. If the dimension is not write-enabled, you must use a tool to modify the data source directly.

User-Defined Hierarchies - Create

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

SQL Server Analysis Services lets you create user-defined hierarchies. A hierarchy is a collection of levels based on attributes. For example, a time hierarchy might contain the Year, Quarter, Month, Week, and Day levels. In some hierarchies, each member attribute uniquely implies the member attribute above it. This is sometimes referred to as a natural hierarchy. A hierarchy can be used by end users to browse cube data. Define hierarchies by using the Hierarchies pane of Dimension Designer in Visual Studio with Analysis Services projects.

When you create a user-defined hierarchy, the hierarchy might become *ragged*. A ragged hierarchy is where the logical parent member of at least one member is not in the level immediately above the member. If you have a ragged hierarchy, there are settings that control whether the missing members are visible and how to display the missing members. For more information, see [Ragged Hierarchies](#).

[Level Properties - user hierarchies](#)

[Parent-Child Dimensions](#)

User-Defined Hierarchies - Ragged Hierarchies

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A ragged hierarchy is a user-defined hierarchy that has an uneven number of levels. Common examples include an organizational chart where a high-level manager has both departmental managers and non-managers as direct reports, or geographic hierarchies composed of Country-Region-City, where some cities lack a parent State or Province, such as Washington D.C., Vatican City, or New Delhi.

For most hierarchies in a dimension, each level has the same number of members above it as any other member at the same level. A ragged hierarchy is different in that the logical parent of at least one member is not in the level immediately above the member. When this occurs, the hierarchy descends to different levels for different drilldown paths. In a client application, this can make drilldown paths unnecessarily complicated.

Client applications vary in how well they handle a ragged hierarchy. If ragged hierarchies exist in your model, be prepared to do a little extra work to get the rendering behavior you expect.

As a first step, check the client application to see how it handles the drilldown path. For example, Excel repeats the parent names as placeholders for missing values. To see this behavior yourself, build a PivotTable using the Sales Territory dimension in the Adventure Works multidimensional model. In a PivotTable having the Sales Territory attributes Group, Country, and Region, you will see that countries missing a region value will get a placeholder, in this case a repeat of the parent above it (Country name). This behavior derives from the MDX Compatibility=1 connection string property that is fixed within Excel. If the client does not naturally provide the drill-down behaviors you are looking for, you can set properties in the model to change at least some of those behaviors.

This topic contains the following sections:

- [Approaches for modifying drilldown navigation in a ragged hierarchy](#)
- [Set HideMemberIf to hide members in a regular hierarchy](#)
- [Set MDX Compatibility to determine how placeholders are represented in client applications](#)

Approaches for modifying drilldown navigation in a ragged hierarchy

The presence of a ragged hierarchy becomes a problem when drilldown navigation does not return expected values or is perceived as awkward to use. To fix navigation problems that result from ragged hierarchies, consider these options:

- Use a regular hierarchy but set the **HideMemberIf** property on each level to specify whether a missing level is visualized to the user. When setting **HideMemberIf**, you should also set **MDXCompatibility** on the connection string to override default navigation behaviors. Instructions for setting these properties are in this topic.
- Create a parent-child hierarchy that explicitly manages the level members. For an illustration of the technique, see [Ragged Hierarchy in SSAS \(blog post\)](#). For more information in Books Online, see [Parent-Child Dimensions](#). Downsides to creating a parent-child hierarchy are that you can only have one per dimension, and you typically incur a performance penalty when calculating aggregations for intermediate members.

If your dimension contains more than one ragged hierarchy, you should use the first approach, setting **HideMemberIf**. BI Developers with practical experience in working with ragged hierarchies go further in

advocating for additional changes in the physical data tables, creating separate tables for each level. See [Martin Mason's the SSAS Financial Cube-Part 1a-Ragged Hierarchies \(blog\)](#) for details about this technique.

Set **HideMemberIf** to hide members in a regular hierarchy

In a ragged dimension's table, the logically missing members can be represented in different ways. The table cells can contain nulls or empty strings, or they can contain the same value as their parent to serve as a placeholder. The representation of placeholders is determined by the placeholder status of child members, as determined by the **HideMemberIf** property, and the **MDX Compatibility** connection string property for the client application.

For client applications that support the display of ragged hierarchies, you can use these properties to hide logically missing members.

1. In SSDT, double-click a dimension to open it in Dimension Designer. The first tab, Dimension Structure, shows attribute hierarchies in the Hierarchies pane.
2. Right-click a member within the hierarchy and select **Properties**. Set **HideMemberIf** to one of the values described below.

| HIDEMEMBERIF SETTING | DESCRIPTION |
|--------------------------------|--|
| Never | Level members are never hidden. This is the default value. |
| OnlyChildWithNoName | A level member is hidden when it is the only child of its parent and its name is null or an empty string. |
| OnlyChildWithParentName | A level member is hidden when it is the only child of its parent and its name is the same as the name of its parent. |
| NoName | A level member is hidden when its name is empty. |
| ParentName | A level member is hidden when its name is identical to that of its parent. |

Set **MDX Compatibility** to determine how placeholders are represented in client applications

After setting **HideMemberIf** on a hierarchy level, you should also set the **MDX Compatibility** property in the connection string sent from the client application. The **MDX Compatibility** setting determines whether the **HideMemberIf** is used.

| MDX COMPATIBILITY SETTING | DESCRIPTION | USAGE |
|---------------------------|---------------------------|---|
| 1 | Show a placeholder value. | This is the default used by Excel, SSDT, and SSMS. It instructs the server to return placeholder values when drilling down empty levels in a ragged hierarchy. If you click the placeholder value, you can continue down to get to the child (leaf) nodes.

Excel owns the connection string used to connect to Analysis Services, and it always sets MDX Compatibility to 1 on each new connection. This behavior preserves backward compatibility. |

| MDX COMPATIBILITY SETTING | DESCRIPTION | USAGE |
|---------------------------|--|---|
| 2 | Hide a placeholder value (either a null value or a duplicate of the parent level), but show other levels and nodes having relevant values. | MDX Compatibility =2 is typically viewed as the preferred setting in terms of ragged hierarchies. A Reporting Services report and some third-party client applications can persist this setting. |

[Parent-Child Dimensions](#)

[Connection String Properties \(Analysis Services\)](#)

User-Defined Hierarchies – Add or Delete a User-Defined Hierarchy

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You add a user-defined hierarchy to or remove a user-defined hierarchy from a dimension on the **Dimension Structure** tab in Dimension Designer in Visual Studio with Analysis Services projects.

When you add a user-defined hierarchy, it is not available to users until it is instantiated in an Analysis Services instance and the dimension is processed. For more information, see [Multidimensional Model Databases](#) and [Processing a multidimensional model \(Analysis Services\)](#).

To add a user-defined hierarchy to a dimension

1. In Visual Studio with Analysis Services projects, open the appropriate Analysis Services project, and then open the dimension with which you want to work.

The dimension opens in Dimension Designer on the **Dimension Structure** tab.

2. From the **Attributes** pane, drag an attribute that you want to use in the user-defined hierarchy to the **Hierarchies** pane.
3. Drag additional attributes to form levels in the user-defined hierarchy.

The order in which attributes are listed in the hierarchy is important. For example, in a time hierarchy, years should appear higher in the hierarchy list than days.

4. Optionally, rearrange the levels in the user-defined hierarchy by dragging them to the correct positions.
5. Optionally, modify properties of the user-defined hierarchy or its levels.

For example, you might want to specify a name for the user-defined hierarchy, rename one or more of its levels, and define a custom name for the All level. For more information, see [User Hierarchy Properties](#), and [Level Properties - user hierarchies](#).

NOTE

By default, a user-defined hierarchy is just a path that enables users to drill down for information. However, if relationships exist between levels, you can increase query performance by configuring attribute relationships between levels. For more information, see [Attribute Relationships](#) and [Define Attribute Relationships](#).

To remove a user-defined hierarchy from a dimension

- On the **Dimension Structure** tab, click the user-defined hierarchy that you want to remove in the **Hierarchies** pane. On the toolbar, click **Delete**.
 - or -
- Right-click the user-defined hierarchy that you want to remove in the **Hierarchies** pane and then click **Delete**.
 - or -
- Drag the user-defined hierarchy off of the design surface.

Attribute Relationships - Define

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Microsoft SQL Server Analysis Services, attributes are the fundamental building block of a dimension. A dimension contains a set of attributes that are organized based on attribute relationships.

For each table included in a dimension, there is an attribute relationship that relates the table's key attribute to other attributes from that table. You create this relationship when you create the dimension.

An attribute relationship provides the following advantages:

- Reduces the amount of memory needed for dimension processing. This speeds up dimension, partition, and query processing.
- Increases query performance because storage access is faster and execution plans are better optimized.
- Results in the selection of more effective aggregates by the aggregation design algorithms, provided that user-defined hierarchies have been defined along the relationship paths.

Attribute Relationship Considerations

When the underlying data supports it, you should also define unique attribute relationships between attributes. To define unique attribute relationships, use the **Attribute Relationships** tab of Dimension Designer.

Any attribute that has an outgoing relationship must have a unique key relative to its related attribute. In other words, a member in a source attribute must identify one and only one member in a related attribute. For example, consider the relationship, City -> State. In this relationship, the source attribute is City and the related attribute is State. The source attribute is the "many" side and the related side is the "one" side of the many-to-one relationship. The key for the source attribute would be City + State. For more information, see [Create, Modify, or Delete an Attribute Relationship](#).

For more information about properties of an attribute relationship, see [Configure Attribute Relationship Properties](#).

NOTE

Defining attribute relationships incorrectly can cause invalid query results.

See Also

[Attribute Relationships](#)

Attribute Relationships - Configure Attribute Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The following table lists and describes the properties of an attribute relationship.

| PROPERTY | DESCRIPTION |
|------------------|---|
| Attribute | Contains the name of the attribute. |
| Cardinality | Indicates the cardinality of the relationship. Values are Many, for a many to one relationship, or One, for a one to one relationship. Default value is Many. In Microsoft SQL Server Analysis Services, the cardinality property has no effect - its use is reserved for a future implementation. |
| Name | Contains the friendly name of the attribute. |
| RelationshipType | Indicates whether member relationships change over time. Values are Rigid, which means that relationships between members do not change over time, or Flexible, which means that relationships between members change over time. Default is Flexible. If you define a relationship as flexible, aggregations are dropped and recomputed as part of an incremental update (they will not be dropped if only new members are added). If you define a relationship as rigid, Analysis Services retains aggregations when the dimension is incrementally updated. If a relationship that is defined as rigid actually changes, Analysis Services generates an error during incremental processing. Specifying the appropriate relationships and relationship properties increases query and processing performance. |
| Visible | Determines the visibility of the attribute relationship. Values are True or False. Default is True. |

Attribute Relationships - Create, Modify, or Delete Relationship

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can create, modify, or delete an attribute relationship between attributes in a dimension by using the **Attribute Relationships** tab of Dimension Designer in Visual Studio with Analysis Services projects.

To create an Attribute Relationship

1. In Dimension Designer, open the dimension that contains the attributes that you want to create an attribute relationship between.
2. On the **Attribute Relationships** tab, right-click an attribute in the diagram or in the **Attributes** pane, and then select **New Attribute Relationship**.

NOTE

To display the **Attributes** pane, click **Show List Views** on the toolbar.

3. In the **Create Attribute Relationship** dialog box, select a source attribute and a related attribute.

4. In the **Relationship type** list, select a relationship type, and then click **OK**.

To modify an Attribute Relationship

1. In Dimension Designer, open the dimension that contains the attribute relationship that you want to modify.
2. Click the **Attribute Relationships** tab.
3. Right-click the attribute relationship in the diagram or in the **Attribute Relationships** pane, and select **Edit Attribute Relationship**.

NOTE

To display the **Attribute Relationships** pane, click **Show List Views** on the toolbar.

4. In the **Edit Attribute Relationship** dialog box, select a source attribute and a related attribute.

5. In the **Relationship type** list, select a relationship type, and then click **OK**.

To delete an Attribute Relationship

1. In Dimension Designer, open the dimension that contains the attribute relationship that you want to delete.
2. On the **Attribute Relationships** tab, right-click the attribute relationship in the diagram or in the **Attribute Relationships** pane, and then select **Delete**.
3. In the **Delete Objects** dialog box, click **OK**.

See Also

[Attribute Relationships](#)

Attribute Relationships - Define the Relationship Type

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You define the relationship type of an attribute relationship by using the **Attribute Relationships** tab in Dimension Designer, which can be accessed from Visual Studio with Analysis Services projects.

To set the relationship type of an attribute relationship

1. In Dimension Designer, open the dimension with which you want to work, and then click on the **Attribute Relationships** tab.
2. In the diagram or in the **Attribute Relationships** pane, right-click the attribute relationship, click **Relationship Type**, and then click either **Flexible** or **Rigid**.

NOTE

To display the **Attribute Relationships** pane, click **Show List Views** on the toolbar.

In a flexible relationship, relationships between members change over time. In a rigid relationship, relationships between members do not change over time.

[Define Attribute Relationships](#)

Attribute Relationships - Arrange Shapes in the Diagram

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can change the layout of the shapes on the **Attribute Relationships** tab of the Dimension Structure view in Dimension Designer in Visual Studio with Analysis Services projects.

To arrange shapes in the attribute relationship diagram

1. In Dimension Designer, open the dimension that contains the attributes that you want to create an attribute relationship between.
2. On the **Attribute Relationships** tab, in the diagram, click a shape to select it, and then grab the shape by the top edge and drag it to the new location.

You can also click **Arrange Shapes** to automatically arrange all shapes according to the layout algorithm that Dimension Designer uses.

[Attribute Relationships](#)

[Define Attribute Relationships](#)

BI Wizard - Add Account Intelligence to a Dimension

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Add the account intelligence enhancement to a cube or a dimension to assign standard account classifications, such as income and expense, to members of an account attribute. This enhancement also identifies account types (such as Asset and Liability) and assigns the appropriate aggregation to each account type. Microsoft SQL Server Analysis Services can use the classifications to aggregate accounts over time.

NOTE

Account intelligence is available only for dimensions that are based on existing data sources. For dimensions that were created without using a data source, you must run the Schema Generation Wizard to create a data source view before adding account intelligence.

You apply account intelligence to a dimension that specifies account information (for example, account name, account number, and account type). To add account intelligence, you use the Business Intelligence Wizard, and select the **Define account intelligence** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply account intelligence, identifying account attributes in the selected account dimension, and then mapping account types in the dimension table to account types recognized by Analysis Services.

Selecting a Dimension

On the first **Define Account Intelligence** page of the wizard, you specify the dimension to which you want to apply account intelligence. The account intelligence enhancement added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

Specifying Account Attributes

On the **Configure Dimension Attributes** page of the wizard, you specify the account attributes in the selected account dimension. First, in the **Include** column, select the check box next to each of the account attribute types that you want to map to a dimension attribute in the dimension. Then, in the **Dimension Attribute** column, expand the drop-down list, and select the attribute in the dimension that corresponds to the selected attribute type. Selecting the attribute from the list sets the attribute **Type** property for the account attributes.

Mapping Account Types

The second **Define Account Intelligence** page maps account type values from the dimension table to account types recognized by Analysis Services. This page appears only if you included the **Account Type** dimension attribute in the dimension. To include the **Account Type** dimension, on the **Define Account Intelligence Settings** page of the wizard, select the check box next to **Account Type**, and then select appropriate attribute.

On the second **Define Account Intelligence** page, there are two columns:

- The **Source Table Account Types** column lists the account types that the wizard obtains from the dimension table.
- The **Server Account Types** column identifies the corresponding account type that Analysis Services recognizes. The following table lists the account types that Analysis Services recognizes and the default

aggregation for each of these types. The selections are made automatically if the dimension table uses the same account type names as Analysis Services uses.

| SERVER ACCOUNT TYPE | AGGREGATION | DESCRIPTION |
|---------------------|---------------------|---|
| Statistical | None | A calculated ratio of something, or a count of something that does not aggregate over time. This type of account does not convert across currencies with conversion rules. |
| Liability | LastNonEmpty | The money or value of things owed at a specific time. This account type does not accumulate over time, and therefore, does not aggregate naturally over time. For example, the Year amount is the value of the last month with data. This type of account converts across currencies with the End of Period rate. |
| Asset | LastNonEmpty | The money or value of things held at a specific time. This account type accumulates over time, and therefore does not aggregate naturally over time. For example, the Year amount is the value of the last month with data. This type of account converts across currencies with the End of Period rate. |
| Balance | LastNonEmpty | The count of something at a specified time. This account type accumulates but does not aggregate naturally over time. For example, the Year amount is the value of the last month with data. |
| Flow | Sum | An incremental count of something. This account type aggregates as a Sum over time but does not convert with currency conversion rules. |
| Expense | Sum | The money or value of things spent. This account type aggregates as a Sum over time and converts across currencies with an average rate. |
| Income | Sum | The money or value of things received. This account type aggregates as a Sum over time and converts across currencies with an average rate. |

NOTE

If appropriate, you can map more than one account type in the dimension to a particular server account type.

To change the default aggregations mapped to each account type for a database, you can use the Database

Designer.

1. In Solution Explorer, right-click the Analysis Services project and click **Edit Database**.
2. In the **Account Type Mapping** box, select an account type in the **Name**.
3. In the **Alias** text box, type an alias for this account type.
4. In the **Aggregation Function** drop down list box, change the default Aggregation Function for this account type.

BI Wizard - Add Dimension Intelligence to a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Add the dimension intelligence enhancement to a cube or a dimension to specify a standard business type for a dimension. This enhancement also specifies the corresponding types for dimension attributes. Client applications can use these type specifications when analyzing data.

To add dimension intelligence, you use the Business Intelligence Wizard, and select the **Define dimension intelligence** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply dimension intelligence and identifying the attributes for the selected dimension.

Selecting a Dimension

On the first **Set Dimension Intelligence Options** page of the wizard, you specify the dimension to which you want to apply dimension intelligence. The dimension intelligence enhancement added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

NOTE

If you select **Account** as the dimension, you will be specifying account intelligence for the dimension. For more information, see [Add Account Intelligence to a Dimension](#).

Specifying Dimension Attributes

On the **Define Dimension Intelligence** page, in **Dimension Type** list, the selection that you make sets the dimension's **Type** property. The **Type** property setting provides information to servers and client applications about the contents of a dimension. Some settings only provide guidance for client applications; these settings are optional. Other settings, such as Accounts or Time, determine specific behaviors and may be required to implement particular business intelligence enhancements. For example, the SQL Server Management Studio uses the dimension type to identify a Currency dimension and set the appropriate currency conversion rules. The default setting for the **Dimension Type** is **Regular**, which makes no assumptions about the contents of the dimension.

After selecting the dimension type, in **Dimension attributes**, in the **Include** column, select the check box next to each standard attribute type for which there is a corresponding attribute in the dimension. Finally, in the **Dimension Attribute** column, expand the drop-down list, and select the attribute in the dimension that corresponds to the selected attribute type. Selecting the attribute from the list sets the attribute **Type** property for the attributes.

For example, you want to add dimension intelligence to an Accounts dimension. In **Dimension Type**, you select **Accounts**. Then, if the dimension has **Account Type** and **Account Description** attributes, in the **Include** column, you select the check boxes for the **Account Name** and **Account Type** account types. In the **Dimension Attribute** column, you then associate these account types with the **Account Description** and **Account Type** attributes, respectively, in the dimension.

[Define Time Intelligence Calculations using the Business Intelligence Wizard](#)

BI Wizard - Add a Custom Aggregation to a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Add a custom aggregation enhancement to a cube or dimension to replace the default aggregations that are associated with a dimension member with a different unary operator. This enhancement specifies a unary operator column in the dimension table that defines rollup for members in a parent-child hierarchy. The unary operator acts on the parent attribute in a parent-child hierarchy.

NOTE

A custom aggregation is available only for dimensions that are based on existing data sources. For dimensions that were created without using a data source, you must run the Schema Generation Wizard to create a data source view before adding the custom aggregation.

To add a custom aggregation, you use the Business Intelligence Wizard, and select the **Specify a unary operator** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply a custom aggregation and identifying the custom aggregation.

NOTE

Before you run the Business Intelligence Wizard to add a custom aggregation, make sure that the dimension that you want to enhance contains a parent-child attribute hierarchy. For more information, see [Parent-Child Dimensions](#).

Selecting a Dimension

On the first **Specify a Unary Operator** page of the wizard, you specify the dimension to which you want to apply a custom aggregation. The custom aggregation added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

Adding Custom Aggregation (Unary Operator)

On the second **Specify a Unary Operator** page, you specify the parent attribute that you want for the custom aggregation and the source column in the dimension table for the unary operator. **Parent attribute** lists attributes that have their **Usage** property set to **Parent**. If there is more than one parent attribute, choose the parent attribute that corresponds to the parent-child relationship that you want to use. If there is no parent attribute listed, then the dimension does not have a valid parent-child hierarchy.

In **Source column**, you select the string column that contains the unary operators. (This selection sets the **UnaryOperatorColumn** property on the parent attribute.) The dimension table should also have a string column that specifies the unary rollup operator. The string values in this column should contain valid aggregation operators. If a row is empty, the corresponding member is calculated normally. If the formula in a column is not valid, a run-time error occurs when a cell value that uses the member is retrieved. For more information, see [Unary Operators in Parent-Child Dimensions](#).

BI Wizard – Custom Member Formulas for Attributes in a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Add a custom member formula enhancement to a cube or dimension to replace the default aggregation that is associated with a dimension member with the results of a Multidimensional Expressions (MDX) expression. (This enhancement sets the **CustomRollupColumn** property on a specified attribute in a dimension.)

NOTE

A custom member formula is available only for dimensions that are based on existing data sources. For dimensions that were created without using a data source, you must run the Schema Generation Wizard to create a data source view before adding a custom member formula.

To add a custom member formula, you use the Business Intelligence Wizard, and select the **Create a custom member formula** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply a custom member formula and enabling the custom member formula.

Selecting a Dimension

On the first **Create a Custom Member Formula** page of the wizard, you specify the dimension to which you want to apply a custom member formula. The custom member formula enhancement added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

Enabling a Custom Member Formula

On the second **Create a Custom Member Formula** page, you associate the source column that contains the custom member formula with one or more attributes in the dimension. In the **Attribute** column, select the check box next to the attribute that you want to associate with the custom member formula column. After you select each attribute, the wizard displays the **Select a Column** dialog box. In this dialog box, click the column in the dimension table that contains the formula. If you want to change a selection after you close the **Select a Column** dialog box, click the **Source Column** cell that you want to change, and then click the ellipsis (...) to open the **Select a Column** dialog box again.

[Use the Business Intelligence Wizard to Enhance Dimensions](#)

BI Wizard - Define the Ordering for a Dimension

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Add the attribute ordering enhancement to a cube or dimension to specify how the members of an attribute are ordered. Members can be ordered by the name or the key of the attribute, or by the name or the key of another attribute (based on an attribute relationship). By default, members are ordered by the name. This enhancement changes the **OrderBy** and **OrderByAttributeID** property settings for attributes in a dimension.

To add attribute ordering, you use the Business Intelligence Wizard, and select the **Specify attribute ordering** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply attribute ordering and specifying how to order the attributes for the selected dimension.

Selecting a Dimension

On the first **Specify Attribute Ordering** page of the wizard, you specify the dimension to which you want to apply attribute ordering. The attribute ordering enhancement added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

Specifying Ordering

On the second **Specify Attribute Ordering** page of the wizard, you specify how all the attributes in the dimension will be ordered.

In the **Ordering Attribute** column, you can change the attribute used to do the ordering. If the attribute that you want to use to order members is not in the list, scroll down the list, and then select **<New attribute...>** to open the **Select a Column** dialog box, where you can select a column in a dimension table. Selecting a column by using the **Select a Column** dialog box creates an additional attribute with which to order members of an attribute.

In the **Criteria** column, you can then select whether to order the members of the attribute by either **Key** or **Name**.

BI Wizard - Enable Dimension Writeback

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Add the dimension writeback enhancement to a cube or dimension to allow users to manually modify the dimension structure and members. Updates to a write-enabled dimension are recorded directly in the dimension table. This enhancement changes the **WriteEnabled** property setting for a dimension.

To add dimension writeback, you use the Business Intelligence Wizard, and select the **Enable dimension writeback** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a dimension to which you want to apply dimension writeback and setting this option for the selected dimension.

NOTE

Writeback is supported for SQL Server relational databases and data marts only.

Selecting a Dimension

On the first **Enable Dimension Writeback** page of the wizard, you specify the dimension to which you want to apply dimension writeback. The dimension writeback enhancement added to this selected dimension will result in changes to the dimension. These changes will be inherited by all cubes that include the selected dimension.

Setting Dimension Writeback Capability

On the second **Enable Dimension Writeback** page of the wizard, you actually set the **Enable writeback in the dimension** option. Selecting this option automatically sets the **WriteEnabled** property of the dimension to **True**. Clearing this option automatically sets the property to **False**.

Remarks

When you create a new member, you must include every attribute in a dimension. You cannot insert a member without specifying a value for the key attribute of the dimension. Therefore, creating members is subject to any constraints (such as non-null key values) that are defined on the dimension table. You should also consider columns optionally specified by dimension properties, such as columns specified in the **CustomRollupColumn**, **CustomRollupPropertiesColumn** or the **UnaryOperatorColumn** dimension properties.

WARNING

If you use SQL Azure as a data source to perform writeback into an Analysis Services database, the operation fails. This is by design, because the provider option that enables multiple active result sets (MARS) is not turned on by default.

The workaround is to add the following setting in the connection string, to support MARS and to enable writeback:

```
"MultipleActiveResultSets=True"
```

For more information see [Using Multiple Active Result Sets \(MARS\)](#).

[Write-Enabled Dimensions](#)

Configure String Storage for Dimensions and Partitions

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can reconfigure string storage to accommodate very large strings in dimension attributes or partitions that exceed the 4 GB file size limit for string stores. If your dimensions or partitions include string stores of this size, you can work around the file size constraint by changing the **StringStoresCompatibilityLevel** property at the dimension or partition level, for local as well as linked (local or remote) objects.

Note that you can increase string storage on just those objects that require additional capacity. In most multidimensional models, string data is associated with dimensions. However, partitions that contain distinct count measures on top of strings can also benefit from this setting. Because the setting is for strings, numeric data is unaffected.

Valid values for this property include the following:

| VALUE | DESCRIPTION |
|-------------|---|
| 1050 | Specifies the default string storage architecture, subject to a 4 GB maximum file size per store. |
| 1100 | Specifies larger string storage, supports up to 4 billion unique strings per store. |

IMPORTANT

Changing the string storage settings of an object requires that you reprocess the object itself and any dependent object. Processing is required to complete the procedure.

This topic contains the following sections:

- [About String Stores](#)
- [Prerequisites](#)
- [Step 1: Set the StringStoreCompatibilityLevel Property in SQL Server Data Tools](#)
- [Step 2: Process the Objects](#)

About String Stores

String storage configuration is optional, which means that even new databases that you create use the default string store architecture that is subject to the 4 GB maximum file size. Using the larger string storage architecture has a small but noticeable impact on performance. You should use it only if your string storage files are close to or at the maximum 4 GB limit.

NOTE

This setting does not apply to data mining models. Currently, it is still possible to encounter the GB file size limitation on models containing data mining structures.

In an Analysis Services multidimensional database, strings are stored separately from numeric data to allow for optimizations based on characteristics of the data. String data is typically found in dimension attributes that represent names or descriptions. It is also possible to have string data in distinct count measures. String data can also be used in keys.

You can identify a string store by its file extension (for example, asstore, .bstore, .ksstore, or .string files). By default, each of these files is subject to a maximum 4 GB limit. In SQL Server 2012 (11.x), you can override the maximum file size by specifying an alternative storage mechanism that allows a string store to grow as needed.

In contrast with the default string storage architecture which limits the size of the physical file, larger string storage is based on a maximum number of strings. The maximum limit for larger string storage is 4 billion unique strings or 4 billion records, whichever occurs first. Larger string storage creates records of an even size, where each record is equal to a 64K page. If you have very long strings that do not fit in a single record, your effective limit will be less than 4 billion strings.

Prerequisites

You must have a SQL Server 2012 (11.x) or later version of Analysis Services.

Dimensions and partitions must use MOLAP storage.

The database compatibility level must be set to 1100. If you created or deployed a database using Visual Studio with Analysis Services projects and the SQL Server 2012 (11.x) or later version of Analysis Services, the database compatibility level is already set to 1100. If you moved a database created in an earlier version of Analysis Services to ssSQL11 or later, you must update the compatibility level. For databases that you are moving, but not redeploying, you can use SQL Server Management Studio to set the compatibility level. For more information, see [Compatibility Level of a Multidimensional Database \(Analysis Services\)](#).

Step 1: Set the **StringStoreCompatibilityLevel** Property in SQL Server Data Tools

1. Using Visual Studio with Analysis Services projects, open the project that contains the dimensions or partitions you want to modify.
2. To change the string storage for dimensions, open Solution Explorer. Double-click the dimension for which you are modifying string storage.
3. In Dimension Designer, in the Attributes pane, make sure that the parent node of the dimension is selected (for example, if the dimension is Customers, select Customers and not one of the child attributes).
4. In the Properties pane, in the Advanced section, set **StringStoresCompatibilityLevel** to **1100**. Repeat for other dimensions that require larger storage, otherwise leave the remaining dimensions at the **1050** value.
5. For partitions, open a cube from Solution Explorer.
6. Click the Partitions tab.
7. Expand the partition, select the partition that requires extra storage capacity, and then modify the **StringStoresCompatibilityLevel** property.
8. Save the file.

Step 2: Process the Objects

The new storage architecture will be used after you process the objects. Processing objects also proves you have successfully resolved storage constraint problem because the error that previously reported a string store overflow condition should no longer occur.

- In Solution Explorer, right-click the dimension or you just modified and select **Process**.

You must use the Process Full option on each object that is using the new string store architecture. Before processing, be sure to run an impact analysis on the dimension to check whether dependent objects also require reprocessing.

[Partition Storage Modes and Processing](#)

[Dimension Storage](#)

Define Linked Dimensions

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A linked dimension is based on a dimension created and stored in another Analysis Services database of the same version and compatibility level. By using a linked dimension, you can create, store, and maintain a dimension on one database, while making it available to users of multiple databases. To users, a linked dimension appears like any other dimension.

Linked dimensions are read-only. If you want to modify the dimension or create new relationships, you must change the source dimension, then delete and recreate the linked dimension and its relationships. You cannot refresh a linked dimension to pick up changes from the source object.

All related measure groups and dimensions must come from the same source database. You cannot create new relationships between local measure groups and the linked dimensions you add to your cube. After linked dimensions and measure groups have been added to the current cube, the relationships between them must be maintained in their source database.

NOTE

Because refresh is not available, most Analysis Services developers copy dimensions rather than link them. You can copy dimensions across projects within the same solution.

Prerequisites

The source database that provides the dimension and the current database that uses it must be at the same version and compatibility level. For more information, see [Compatibility Level of a Multidimensional Database \(Analysis Services\)](#).

The source database must be deployed and online. Servers that publish or consume linked objects must be configured to allow the operation (see below).

The dimension you want to use cannot itself be a linked dimension.

Configure server to allow linked objects

1. In SQL Server Management Studio, connect to an Analysis Services server. In Object Explorer, right-click the server name and select **Facets**.
2. Set **LinkedObjectsLinksFromOtherInstancesEnabled** to **True** to allow the server to issue requests for linked objects that reside in databases running on other instances.
3. Set **LinkedObjectsLinksToOtherInstances** to **True** to allow the server to request data for linked on databases running on other instances.

Create a linked dimension in SQL Server Data Tools

1. Start the wizard. In Visual Studio with Analysis Services projects, right-click the **Dimensions** folder in an Analysis Services database or project, and then click **New Linked Dimension**.
2. Connect to the Analysis Services database that provides the dimension. On the **Select a Data Source** page

of the Linked Object Wizard, choose the Analysis Services data source or create a new one.

3. On the **Select Objects** page of the wizard, choose the dimensions you want to link to in the remote database.
4. On the **Completing the Wizard** page, you can preview the linked objects. If you link a dimension that has the same name as one that already exists, an ordinal number (starting with '1' for the first duplicated name) is appended to the name. When you complete the wizard, the dimension is added to the **Dimensions** folder.

Create a New Data Source Connection to an Analysis Services Database

Use the New Data Source wizard to add to your project connection information about the Analysis Services database that provides the dimension. You can start the wizard by clicking **New Data Source** in the Select a Data Source page of the Linked Objects wizard.

1. In the Data Source Wizard, on the Select how to define the connection page, click **New**.
2. In Connection Manager, verify that the provider is set to **Native OLE DB\Microsoft OLE DB Provider for Analysis Services 11.0**.
3. Enter the name of the server (use *servername\instancename* for a named instance) or type **localhost** to connect to an Analysis Services server that is running on the same computer.
4. Use Windows authentication for the connection.
5. In **Initial catalog**, click the down arrow to select a database on this server.
6. On the Data Source Wizard, click **Next** to continue.
7. On the Impersonation Information page, click **Use the service account**. Click **Next**, and then finish the wizard. The connection you just defined will be selected in the Linked Objects Wizard.

Next Steps

You cannot change the structure of a linked dimension, so you cannot view it with the **Dimension Structure** tab of Dimension Designer. After processing the linked dimension, you can view it with the **Browser** tab. You can also change its name and create a translation for the name.

[Dimension Relationships](#)

Cubes in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A cube is a multidimensional structure that contains information for analytical purposes; the main constituents of a cube are dimensions and measures. Dimensions define the structure of the cube that you use to slice and dice over, and measures provide aggregated numerical values of interest to the end user. As a logical structure, a cube allows a client application to retrieve values, of measures, as if they were contained in cells in the cube; cells are defined for every possible summarized value. A cell, in the cube, is defined by the intersection of dimension members and contains the aggregated values of the measures at that specific intersection.

Benefits of Using Cubes

A cube provides a single place where all related data, for analysis, is stored.

Components of Cubes

A cube is composed of:

| ELEMENT | DESCRIPTION |
|----------------------------------|---|
| Dimensions | Dimensions in Multidimensional Models |
| Measures and Measure Groups | Create Measures and Measure Groups in Multidimensional Models |
| Partitions | Partitions in Multidimensional Models |
| Perspectives | Perspectives in Multidimensional Models |
| Hierarchies | Create User-Defined Hierarchies |
| Actions | Actions in Multidimensional Models |
| Key Performance Indicators (KPI) | Key Performance Indicators (KPIs) in Multidimensional Models |
| Calculations | Calculations in Multidimensional Models |
| Translations | Translations in Multidimensional Models (Analysis Services) |

Related Tasks

| TOPIC | DESCRIPTION |
|---|--|
| Create a Cube Using the Cube Wizard | Describes how to use the Cube Wizard to define a cube, dimensions, dimension attributes, and user-defined hierarchies. |

| TOPIC | DESCRIPTION |
|---|---|
| Create Measures and Measure Groups in Multidimensional Models | Describes how to define measure groups. |
| Calculations in Multidimensional Models | Describes how to define and configure a calculation in an MDX script. |
| Actions in Multidimensional Models | Describes how to define and configure an action. |
| Perspectives in Multidimensional Models | Describes how to define and configure a perspective. |

Create a Cube Using the Cube Wizard

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can create a new cube by using the Cube Wizard in Visual Studio with Analysis Services projects.

To create a new cube

1. In **Solution Explorer**, right-click **Cubes**, and then click **New Cube**.
2. On the **Select Creation Method** page of the Cube Wizard, select **Use existing tables**, and then click **Next**.

NOTE

You might occasionally have to create a cube without using existing tables. To create an empty cube, select **Create an empty cube**. To generate tables, select **Generate tables in the data source**.

3. On the **Select Measure Group Tables** page, do the following procedures:
 - a. In the **Data source view** list, select a data source view.
 - b. In the **Measure group tables** list, select the tables that will be used to create measure groups.
 - c. Click **Next**.
4. On the **Select Measures** page, select the measures that you want to include in the cube, and then click **Next**.

Optionally, you can change the names of the measures and measure groups.

5. On the **Select Existing Dimensions** page, select the existing dimensions to include in the cube, and then click **Next**.

NOTE

The **Select Existing Dimensions** page appears if dimensions already exist in the database for any of the selected measure groups.

6. On the **Select New Dimensions** page, select the new dimensions to create, and then click **Next**.

NOTE

The **Select New Dimensions** page appears if any tables would be good candidates for dimension tables, and the tables have not already been used by existing dimensions.

7. On the **Select Missing Dimension Keys** page, select a key for the dimension, and then click **Next**.

NOTE

The **Select Missing Dimension Keys** page appears if any of the dimension tables that you specified do not have a key defined.

8. On the **Completing the Wizard** page, enter a name for the new cube and review the cube structure. If you want to make changes, click **Back**; otherwise, click **Finish**.

NOTE

You can use Cube Designer after you complete the Cube Wizard to configure the cube. You can also use Dimension Designer to add, remove, and configure attributes and hierarchies in the dimensions that you created.

Create a Cube from a template without using a Data Source View

7/16/2019 • 9 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Select **Build the cube without using a data source** on the first page of the Cube Wizard to create a cube without using a data source view. You can later use the Schema Generation Wizard to generate the relational schema for the data source view based on the structure of the cube and possibly other Analysis Services objects. For more information about generating a schema, see [Schema Generation Wizard \(Analysis Services\)](#).

Selecting the Build Method

In the Cube Wizard, on the **Select Build Method** page, click **Build the cube without using a data source**. To build the cube by using an existing cube template, select the **Use a cube template** check box. If you do not select to use a template, you must set the options manually.

Cube templates contain predefined measures, measure groups, dimensions, hierarchies, and attributes. If you select a template, the wizard uses the object definitions in the templates as the basis for setting options in the following pages. Analysis Services is installed with several templates for standard cubes. The server administrator can also add cube or dimension templates that are designed specifically for your organization's data.

Selecting Dimensions

Use the **Select Dimensions** page of the wizard to add existing dimensions to the cube. This page appears only if there are already shared dimensions without a data source in the project or database. It does not list dimensions that have a data source.

To add existing dimensions, select one or more dimensions in the **Shared dimensions** list and click the right arrow (>) button to move them to the **Cube dimensions** list. Click the double-arrow (>>) button to move all the dimensions in the list.

Defining New Measures

Use the **Define New Measures** page of the wizard to specify the measures and measure groups in the new cube. The measure groups you specify here will correspond to fact tables in the generated schema. The measures you specify here will correspond to numeric non-key columns in the tables.

If you use a template to create the cube, measures in the template are listed in grid format under **Select measures from template**. The check box next to every measure in the list is initially selected. You can clear the check box next to any measure that you do not want to include in the cube. To add or remove all the measures in the list, select or clear the check box on the title bar of the grid.

You can add measures to the cube in the list under **Add new measures**. To add a new measure, click the first empty cell in the **Measure Name** column (which displays **Add new measure**). Specify a measure name, measure group, data type, and aggregation for each new measure. To delete a measure from the **Add new measures** list, click the delete icon (X). If you do not use a template, **Add new measures** is the only list on this page of the wizard.

Both the **Select measures from template** grid and the **Add new measures** grid display values under the columns described in the following table. You can click a value in either list to change it.

| COLUMN | DESCRIPTION |
|----------------------|--|
| Measure Name | A value in this column defines the name of a measure in the cube. Click a value in this column to type a name. Click Add new measure in this column to create a new measure. This column sets the Name property on the measure object. |
| Measure Group | The name of the measure group that contains the measure. Click this value to either choose or type a name. If you delete all the measures that belong to a particular measure group, the measure group is removed as well. This column sets the Name property for the measure group object. |
| Data Type | The data type for the measure. Click this value to change the data type. The default when you create a measure is Single . This column sets the DataType property on the measure object. |
| Aggregation | The standard aggregation for the measure. Click this cell to specify one of the standard aggregations for the measure (or None). The default when you create a measure is Sum . This column sets the AggregationFunction property on the measure object. |

Defining New Dimensions

Use the **Define New Dimensions** page of the wizard to specify the dimensions in the new cube.

If you use a template to create the cube, the grid under **Select dimensions from template** displays the dimensions in the template. You can clear the check box next to any dimension to remove it from the cube. Clear the check box on the title bar of the grid to remove all the dimensions listed. If you do not use a template, this grid lists only the Time dimension.

You can add dimensions to the cube in the grid under **Add new dimensions**. To add a dimension, click the cell in the **Name** column that contains the text **Add new dimension**, and then type a name for the dimension. To remove a row from the list, click the delete icon (X).

Both the **Select dimensions from template** grid and the **Add new dimensions** grid display values under the columns described in the following table. You can click a value in either list to change it.

| COLUMN | DESCRIPTION |
|-------------|---|
| Type | Displays the dimension type for a template dimension. Click this cell to change the dimension type for a dimension. This column sets the Type property for the dimension object. |
| Name | Displays the dimension name. Click this cell to type a different name. This value sets the Name property for the dimension object. |
| SCD | Specifies that this is a slowly changing dimension (SCD). Selecting this check box adds the SCD Start Date, End Date Original ID, and Status attributes to the dimension. SCD is selected by default if you use a template to create the cube and the wizard detects these four attribute types in a template dimension. |

| COLUMN | DESCRIPTION |
|-------------------|---|
| Attributes | Displays the attributes that are to be created for the dimension. Each attribute name in the list is preceded by the dimension name. This list is read-only. You can edit the attributes by using Dimension Designer after you complete the wizard. |

Defining Time Periods

Use the **Define Time Periods** page of the wizard to specify the range of dates you want to include in the dimension. For example, you might choose a range starting on January 1 of the earliest year in your data and extending years past your most current transaction. Transactions that are outside the range either do not appear or appear as unknown members in the dimension, depending on the **UnknownMemberVisible** property setting for the dimension. The **UnknownMemberName** property specifies the caption for the unknown member. You can also change the first day of the week used by your data (the default is Sunday).

NOTE

The **Define Time Periods** page appears only if you include a time dimension in your cube on the **Define New Dimensions** page of the wizard.

Select the time periods (**Year**, **Half Year**, **Quarter**, **Trimester**, **Month**, **Ten Days**, **Week**, and **Date**) that you want to include in your schema. You must select the Date time period; the Date attribute is the key attribute for the dimension, so the dimension cannot function without it. You can also change the language used to label the members of the dimension.

The time periods you select create corresponding time attributes in the new time dimension. The wizard also adds related attributes that do not appear in the list. For example, when you select **Year** and **Half Year** time intervals, the wizard creates Day of Year, Day of Half Year, and Half Years of Year attributes, in addition to Year and Half Year attributes.

After you finish creating the cube, you can use Dimension Designer to add or remove time attributes. Because the Date attribute is the key attribute for the dimension, you cannot remove it. To hide the Date attribute from users, you can change the **AttributeHierarchyVisible** property to **False**.

All the available time periods appear in the Time Periods pane of Dimension Designer. (This pane replaces the **Data Source View** pane for dimensions that are based on dimension tables.) You can change the range of dates for a dimension by changing the **Source** (time binding) property setting for the dimension. Because this is a structural change, you must reprocess the dimension and any cubes that use it before browsing the data.

Specifying Additional Calendars

On the **Specify Additional Calendars** page of the wizard, select calendars on which to base hierarchies in the dimension. You can choose any of the following calendars.

| CALENDAR | DESCRIPTION |
|-----------------|--|
| Fiscal calendar | A twelve-month fiscal calendar. If you select this calendar, specify the starting day and month for the fiscal year used by your organization. |

| CALENDAR | DESCRIPTION |
|-----------------------------------|---|
| Reporting (or marketing) calendar | A twelve-month reporting calendar that includes two months of four weeks and one month of five weeks in a recurring three-month (quarterly) pattern. If you select this calendar, specify the starting day and month and the three-month pattern of 4-4-5, 4-5-4, or 5-4-4 weeks, where each digit represents the number of weeks in a month. |
| Manufacturing calendar | A calendar that uses 13 periods of four weeks, divided into three quarters of four periods and one quarter of five periods. If you select this calendar, specify the starting week (between 1 and 4) and month for the manufacturing year, and the quarter with extra periods. |
| ISO 8601 Calendar | The International Organization for Standardization (ISO) Representation of Dates and Time standard calendar (8601). This calendar has an integral number of 7-day weeks. To avoid splitting a week, this calendar starts a new year up to several days before or after January 1. |

The calendar and settings you select determine the attributes that are created in the dimension. For example, if you select the **Year** and **Quarter** time periods on the **Define Time Periods** page of the wizard and the **Fiscal calendar** on this page, the FiscalYear, FiscalQuarter, FiscalQuarterOfYear attributes are created for the fiscal calendar.

The wizard also creates calendar-specific hierarchies composed of the attributes that are created for the calendar. For every calendar, each level in every hierarchy rolls up into the level above it. For example, in the standard 12-month calendar, the wizard creates a hierarchy of Years and Weeks or Years and Months. However, weeks are not contained evenly within months in a standard calendar, so there is no hierarchy of Years, Months, and Weeks. In contrast, weeks in a reporting or manufacturing calendar are evenly divided into months, so in these calendars weeks do roll up into months.

Defining Dimension Usage

Use the **Define Dimension Usage** page of the wizard to specify which cube measures are aggregated by each dimension in the wizard. The **Dimension usage** grid on this page lists the dimensions as rows and measure groups as columns. Select the check box for any dimension and measure group combination in which the dimension aggregates the measures of that measure group.

Completing the Cube Wizard

On the **Completing the Wizard** page, review the structure of the new cube and in the **Cube name** box, type a name for it. Optionally, select the **Generate schema now** check box to start the schema generation wizard. In most cases, you should not select this check box if you plan to create additional objects. You can also use Cube Designer to generate the schema later.

Create a Cube using a Data Source View

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use this method of building a new cube if you intend to use an existing data source view. With this method, you specify the data source view and select fact and dimension tables that you want to use in the data source view. You then choose the dimensions and measures that you want to include in the cube.

To create a cube with a data source, in Solution Explorer, right-click **Cubes** and select **New Cube**. The Cube Wizard opens.

Selecting the Build Method

On the **Select Build Method** page of the wizard, click **Build the cube using a data source**.

If you select the **Auto build** check box, the wizard analyzes the data source view to configure the cube and its dimensions for you. The wizard identifies fact and dimension tables, selects measures to include in the cube, and builds hierarchies. On each page of the wizard, you can examine and change the choices that the wizard makes when **Auto build** is selected. If you do not select **Auto build**, you make all these choices manually.

If you select **Auto build**, you can click **Finish** on any page of the wizard to jump to the last page and accept the default configurations for any remaining pages of the wizard. On the last page of the wizard, you can review the structure of the cube before finishing the wizard.

If you do not select **Auto build**, you must select the fact and dimension tables yourself. The wizard builds any dimensions that you choose to create, but you must use Dimension Designer to manually build user-defined hierarchies in the dimensions. This requirement may not make any difference if you have already created the dimensions you want to use in the cube before running the Cube Wizard.

Selecting the Data Source View

If you use an existing data source to create a cube, the first step is to specify the data source view on which to base the cube. On the **Select Data Source View** page of the wizard, select an existing data source view. In the preview pane, you can view the tables in a selected data source view. To display the schema for any selected data source view, click **Browse**.

If the data source view you want to use is not listed, in the Cube Wizard, click **Cancel**, and open the Data Source View Wizard. You can also click **Add New Item** on the **File** menu to add an existing data source view from another database (or other location). For more information about creating data source views, see [Data Source Views in Multidimensional Models](#).

NOTE

A data source view must contain at least one table to be listed on this page. You cannot create a cube based on a data source view that does not have any tables.

Identify Fact and Dimension Tables

In the Cube Wizard, use the **Identify Fact and Dimension Tables** page of the wizard to select the fact and dimension tables required to create the cube. If you selected the **Auto build** check box to create the cube, the fact

or dimension tables the wizard detects are selected when this page first appears. If the wizard detects a table that is both a fact table and a dimension table, both columns are selected. If the wizard detects a table that is neither, neither column is selected. If you do not need a table for your cube design, clear the **Fact** and **Dimension** check boxes.

If you did not select the **Auto build** check box, you must make all the selections manually. Use the **Tables** tab or the **Diagram** tab:

- The **Tables** tab lists the tables in table format. Select the check box in the **Fact** column or the **Diagram** column.
- The **Diagram** tab displays the data source view schema. Tables are color coded to indicate fact or dimension. Click any table in the schema, and then click **Fact** or **Dimension** to select or clear the setting on that table. Use the **Zoom** button to change the magnification.

NOTE

On the **Diagram** tab, you can enlarge or maximize the wizard window to view the schema.

If there is a time dimension table in the data source view, select it in the **Time dimension table** list. If there are none, leave **<None>** selected. This is the default item on the list. Selecting a table as the time dimension table also selects it as a dimension table on the **Tables** and **Diagram** tabs.

Defining Time Periods

If you specified a time dimension table while selecting table types, use the **Define Time Periods** page of the wizard to specify the columns in the table that correspond to standard time periods. Look for the standard periods under **Time Property Name**. For each row that has a corresponding column in the time dimension table, choose the correct column under **Time Table Columns**. The wizard uses the associations you specify to create attributes and suggest time hierarchies that make sense for your data. These associations also set the **Type** property for the corresponding attributes in the new time dimension. The wizard then creates a time dimension based on a time dimension table.

After you create the cube, you can use the Business Intelligence Wizard to add time intelligence enhancements to the cube. These enhancements include period-to-date, rolling average, and period-to-period views.

Selecting Dimensions

Use the **Select Dimensions** page of the wizard to add existing dimensions to the cube. This page appears only if there are already shared dimensions that correspond to dimension tables in the new cube.

To add existing dimensions, select one or more dimensions in the **Shared dimensions** list and click the right arrow (>) button to move them to the **Cube dimensions** list. Click the double-arrow (>>) button to move all the dimensions in the list.

If an existing dimension does not appear in the list and you think it should, you can click **Back** and change the table type settings for one or more tables. An existing dimension must also be related to at least one of the fact tables in the cube to appear in the **Shared dimensions** list.

Selecting Measures

Use the **Select Measures** page of the wizard to select the measures you want to include in the cube. Every table marked as a fact table appears as a measure group in this list, and every numeric non-key column appears as a measure on the list. By default every measure in every measure group is selected. You can clear the check box next to measures that you do not want to include in the cube. To remove all the measures of a measure group from the

cube, clear the **Measure Groups/Measures** check box.

The names of measures listed under **Measure Groups/Measures** reflect column names. You can click the cell that contains a name to edit the name.

To view data for any measure, right-click any of the measure rows in the list, and then click **View sample data**.

This opens the **Data Sample Viewer** and displays up to the first 1000 records from the corresponding fact table.

Reviewing New Dimensions

Use the **Review New Dimensions** page of the wizard to review the structures of any dimensions created by the wizard. The dimensions are listed on this page of the wizard in the **New dimensions** tree view. You can review the dimensions in the following ways:

- Expand any dimension to view its attributes and hierarchies.
- Expand the **Attributes** folder under any dimension to view the attributes in the dimension.
- Expand the **Hierarchy** folder under any dimension to view the hierarchies in the dimension.
- Expand any hierarchy to view its levels.

NOTE

You can enlarge or maximize the wizard window to view the tree better.

To remove any object in the tree from the cube, clear the check box next to it. Clearing the check box next to an object also removes all the objects underneath it. Dependencies between objects are enforced, so if you remove an attribute, any hierarchy levels dependent on the attribute are also removed. For example, clearing a check box next to a hierarchy clears the check boxes next to all the levels in the hierarchy and removes the levels as well as the hierarchies. The key attribute for a dimension cannot be removed.

You can rename any dimension, attribute, hierarchy or level either by clicking the name or by right-clicking the name and then on the shortcut menu clicking **Rename <object>**, where **<object>** is **Dimension**, **Attribute**, or **Level**.

There is not necessarily a one-to-one relationship between the number of dimension tables defined on the **Identify Fact and Dimension Tables** page of the wizard and the number of dimensions listed on this page of the wizard. Depending on relationships between tables in the data source view, the wizard can use two or more tables to build a dimension (for example, as required by a snowflake schema).

Completing the Cube Wizard

On the **Completing the Wizard** page of the wizard, you can view the measure groups, measures, and dimensions in the new cube. In the **Cube name** box, type a name for the cube. Then, if you are satisfied with the cube, click **Finish**. Click **Back** to go back to any previous page of the wizard and make changes.

Browse data and metadata in Cube

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use the **Browser** tab of Cube Designer to browse cube data. You can use this view to examine the structure of a cube and to check data, calculation, formatting, and security of database objects. You can quickly examine a cube as end users see it in reporting tools or other client applications. When you browse cube data, you can view different dimensions, drill down into members, and slice through dimensions.

Before you browse a cube, you must process it and the reconnect to it. After you process it, open the **Browser** tab of Cube Designer. Click the Reconnect button on the toolbar to refresh the connection.

The **Browser** tab has three panes - the Metadata pane, the Filter pane, and the Data pane. Use the Metadata pane to examine the structure of the cube in tree format. Use the Filter pane at the top of the **Browser** tab to define any subcube you want to browse. Use the Data pane to view the result set and drill down through dimension hierarchies.

Setting up the Browser

To prepare to browse a cube, you can specify a perspective or translation that you want to use. You add measures and dimensions to the Data pane and specify any filters in the Filter pane.

Specifying a Perspective

Use the **Perspective** list to choose a perspective that is defined for the cube. Perspectives are defined in the **Perspectives** tab of Cube Designer. To switch to a different perspective, select any perspective in the list.

Specifying a Translation

Use the **Language** list to choose a translation that is defined for the cube. Translations are defined in the **Translations** tab of Cube Designer. The **Browser** tab initially shows captions for the default language, which is specified by the **Language** property for the cube. To switch to a different language, select any language in the list.

Formatting the Data Pane

You can format captions and cells in the Data pane. Right-click the selected cells or captions that you want to format, and then click **Commands and Options**. Depending on the selection, the **Commands and Options** dialog box displays settings for **Format**, **Filter and Group**, **Report**, and **Behavior**.

Setting up the Data

Adding or Removing Measures

Drag the measures you want to browse from the Metadata pane to the details area of the Data pane, which is the large empty pane on the lower right side of the workspace. As you drag additional measures, they are added as columns. A vertical line indicates where each additional measure will drop. Dragging the **Measures** folder drops all the measures into the details area.

To remove a measure from the details area, either drag it out of the Data pane, or right-click it and then click **Delete** on the shortcut menu.

Adding or Removing Dimensions

Drag the hierarchies or dimensions to the row or filter areas.

If you want to work with multiple dimensions, use Analyze in Excel. Analyze in Excel is a shortcut that starts Excel if it is installed on the same computer as Visual Studio with Analysis Services projects. Excel will open a workbook that contains an existing connection to the current database and a PivotTable Field List that is preloaded with measures and dimensions. For more information, see [Analyze in Excel \(Browser Tab, Cube Designer\) \(Analysis\)](#)

Services - Multidimensional Data).

To remove a dimension, either drag it out of the Data pane, or right-click it and then click **Delete** on the shortcut menu.

Adding or Removing Filters

You can use either of two methods to add a filter:

- Expand a dimension in the Metadata pane, and then drag a hierarchy to the Filter pane.
- OR -
- In the **Dimension** column of the **Filter** pane, click <**Select dimension**> and select a dimension from the list, then click <**Select hierarchy**> in the **Hierarchy** column and select a hierarchy from the list.

After you specify the hierarchy, specify the operator and filter expression. The following table describes the operators and filter expressions.

| OPERATOR | FILTER EXPRESSION | DESCRIPTION |
|-------------------|--|---|
| Equal | One or more members | Values must be equal to a specified member.

(Provides multiple member selection for attribute hierarchies, other than parent-child hierarchies, and single member selection for other hierarchies.) |
| Not Equal | One or more members | Values must not equal a specified member.

(Provides multiple member selection for attribute hierarchies, other than parent-child hierarchies, and single member selection for other hierarchies.) |
| In | One or more named sets | Values must be in a specified named set.

(Supported for attribute hierarchies only.) |
| Not In | One or more named sets | Values must not be in a specified named set.

(Supported for attribute hierarchies only.) |
| Range (Inclusive) | One or two delimiting members of a range | Values must be between or equal to the delimiting members. If the delimiting members are equal or only one member is specified, no range is imposed and all values are permitted.

(Supported only for attribute hierarchies. The range must be on one level of a hierarchy. Unbounded ranges are not currently supported.) |

| OPERATOR | FILTER EXPRESSION | DESCRIPTION |
|-------------------|--|--|
| Range (Exclusive) | One or two delimiting members of a range | Values must be between the delimiting members. If the delimiting members are the equal or only one member is specified, values must be either greater than or less than the delimiting member.

(Supported only for attribute hierarchies. The range must be on one level of a hierarchy. Unbounded ranges are not currently supported.) |
| MDX | An MDX expression returning a member set | Values must be in the calculated member set. Selecting this option displays the Calculated Member Builder dialog box for creating MDX expressions. |

For user-defined hierarchies, in which multiple members may be specified in the filter expression, all the specified members must be at the same level and share the same parent. This restriction does not apply for parent-child hierarchies.

Working with Data

Drilling Down into a Member

To drill down into a particular member, click the plus sign (+) next to the member or double-click the member.

Slicing Through Cube Dimensions

To filter the cube data, click the drop-down list box on the top-level column heading. You can expand the hierarchy and select or clear a member on any level to show or hide it and all its descendants. Clear the check box next to **(All)** to clear all the members in the hierarchy.

After you have set this filter on dimensions, you can toggle it on or off by right-clicking anywhere in the Data pane and clicking **Auto Filter**.

Filtering Data

You can use the filter area to define a subcube on which to browse. You can add a filter by either clicking a dimension in the Filter pane or by expanding a dimension in the Metadata pane and then dragging a hierarchy to the Filter pane. Then specify an **Operator** and **Filter Expression**.

Performing Actions

A triangle marks any heading or cell in the Data pane for which there is an action. This might apply for a dimension, level, member, or cube cell. Move the pointer over the heading object to see a list of available actions. Click the triangle in the cell to display a menu and start the associated process.

For security, the **Browser** tab only supports the following actions:

- URL
- Rowset
- Drillthrough

Command Line, Statement, and Proprietary actions are not supported. URL actions are only as safe as the Web page to which they link.

Viewing Member Properties and Cube Cell Information

To view information about a dimension object or cell value, move the pointer over the cell.

Showing or Hiding Empty Cells

You can hide empty cells in the data grid by right-clicking anywhere in the Data pane and clicking **Show Empty Cells**.

View the Cube Schema

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The **Data Source View** pane of the **Cube Structure** tab in **Cube Designer** displays the cube schema. The schema is the set of tables from which the measures and dimensions for a cube are derived. Every cube schema consists of one or more fact tables and one or more dimension tables on which the measures and dimensions in the cube are based.

The **Data Source View** pane of the **Cube Structure** tab displays a diagram of the data source view on which the cube is based. This diagram is a subset of the main diagram of the data source view. You can hide and show tables in the **Data Source View** pane and view any existing diagrams. However, you cannot make changes (such as adding new relationships or named queries) to the underlying schema. To make changes to the schema, use Data Source View Designer.

When you create a cube, the diagram displayed in the **Data Source View** pane of the **Cube Structure** tab is initially the same as the **Show All Tables** diagram in the data source view for the project or database. You can replace this diagram with any existing diagram in the data source view and make adjustments in the **Data Source View** pane.

While you work with the diagram in **Cube Designer**, commands that act on the tab or on any selected object in the tab are available on the **Data Source View** menu. You can also right-click the background of the diagram or any object in the diagram to use commands that act on the diagram or selected object. You can:

- Switch between diagram and tree formats.
- Arrange, find, show, and hide tables.
- Show friendly names.
- Switch layouts.
- Change the magnification.
- View properties.

Additionally, you can perform the actions listed in the following table:

| TO | DO THIS |
|---|---|
| Use a diagram from the data source view of the cube | <p>On the Data Source View menu, point to Copy Diagram from, and then click the data source view diagram you want to use.</p> <p>- or -</p> <p>Right-click the background of the Data Source View pane, point to Copy Diagram from, and then click the diagram in the data source view that you want. This method creates an independent copy of the diagram, so any changes you make on the Cube Builder tab do not appear in the original diagram.</p> |

| TO | DO THIS |
|--|---|
| Show only the tables that are used in the cube | <p>On the Data Source View menu, click Show Only Used Tables.</p> <p>- or -</p> <p>Right-click the background of the Data Source View pane, and then click Show Only Used Tables.</p> |
| Edit the data source view schema | <p>On the Data Source View menu, click Edit Data Source View.</p> <p>- or -</p> <p>Right-click the background of the Data Source View pane, and then click Edit Data Source View.</p> |

Define Cube Dimension Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A cube dimension is an instance of a database dimension within a cube. A database dimension can be used in multiple cubes, and multiple cube dimensions can be based on a single database dimension. The following table describes the properties of a cube dimension.

| PROPERTY | DESCRIPTION |
|----------------------------------|--|
| AllMemberAggregationUsage | Controls how aggregations are designed by the Aggregation Designer in Microsoft SQL Server Analysis Services. This property can have the following values:

Full: Every aggregation for the cube must include the All member.

None: No aggregation for the cube can include the All member. This is the default value.

Unrestricted: No restrictions are placed on the Aggregation Designer.

Default: The same functionality as Unrestricted. |
| Description | Provides a descriptive name for the level. |
| DimensionID | Contains the unique identifier (ID) of the database dimension. |
| HierarchyUniqueNameStyle | Determines how unique names are generated for hierarchies that are contained within the cube dimension. This property can have the following values:

IncludeDimensionName:
The name of the dimension is included as part of the name of the hierarchy. This is the default value.

ExcludeDimensionName:
The name of the dimension is not included as part of the name of the hierarchy. |
| ID | Contains the unique identifier of the cube dimension. |
| MemberUniqueNameStyle | Determines how unique names are generated for members of hierarchies contained within the cube dimension. This property can have the following values:

Native:
Analysis Services automatically determines the unique names of members. This is the default value.

NamePath: Analysis Services generates a compound name consisting of the name of each level and the caption of the member. |

| PROPERTY | DESCRIPTION |
|----------------|--|
| Name | Contains the friendly name of the cube dimension. By default, the name of a cube dimension is the same as the name of the database dimension, unless another cube dimension of the same name is already defined. |
| Visible | Determines whether the cube dimension is visible. The default value is True . |

Define Cube Hierarchy Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Cube hierarchy properties enable you to specify unique settings for user-defined hierarchies in cube dimensions based on the same database dimension. The following table describes the properties of a cube hierarchy.

| PROPERTY | DESCRIPTION |
|-----------------------|--|
| Enabled | Determines whether the hierarchy is enabled for the cube dimension. |
| HierarchyID | Contains the unique identifier (ID) of the hierarchy. |
| OptimizedState | Determines the level of optimization that is applied to the hierarchy. This property can have the following values:

FullyOptimized:
The instance builds indexes for the hierarchy to improve query performance. This is the default value.

NotOptimized:
The instance does not build additional indexes. |
| Visible | Determines the visibility of the cube hierarchy. The default value is True . |

Define Cube Attribute Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Cube attribute properties enable you to specify unique settings for dimension attributes in cube dimensions based on the same database dimension. The following table describes the properties of a cube attribute.

| PROPERTY | DESCRIPTION |
|----------------------------------|--|
| AggregationUsage | <p>Specifies how the Aggregation Design Wizard will design aggregations for the attribute. The default value is Default. This property can have the following values:</p> <p>Default:
The Aggregation Design Wizard applies a default rule based on the type of attribute (Full for keys, Unrestricted for others).</p> <p>None:
No aggregation for the cube should include this attribute.</p> <p>Unrestricted:
No restrictions are placed on the Aggregation Design Wizard</p> <p>Full:
Every aggregation for the cube must include this attribute.</p> |
| AttributeHierarchyEnabled | <p>Identifies whether the attribute hierarchy is enabled on this cube dimension. This allows attribute hierarchies to be disabled on specific cubes or dimension roles. This setting has no effect if the underlying attribute hierarchy is disabled. Default value is True.</p> |
| OptimizedState | <p>Indicates whether the attribute hierarchy is optimized on this cube dimension. This allows attribute hierarchies to be optimized on specific cubes or dimension roles. This setting has no effect if the underlying attribute hierarchy is not optimized. The default value is FullyOptimized. This property can have the following values:</p> <p>FullyOptimized: The instance builds indexes for the hierarchy to improve query performance. This is the default value.</p> <p>NotOptimized:
The instance does not build additional indexes.</p> |
| AttributeHierarchyVisible | <p>Indicates whether the attribute hierarchy is visible on this cube dimension. This allows attribute hierarchies to be visible on specific cubes or dimension roles. This setting has no effect if the underlying attribute hierarchy is not visible. The default value is True.</p> |
| AttributeID | Contains the unique identifier (ID) of the attribute. |

[Define Cube Hierarchy Properties](#)

Define a Regular Relationship and Regular Relationship Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

When you define a new cube dimension or a new measure group, Analysis Services will try to detect if a regular relationship exists and then set the dimension usage setting to **Regular**. You can view or edit a regular dimension relationship on the **Dimension Usage** tab of Cube Designer.

When you define the relationship of a cube dimension to a measure group, you also specify the granularity attribute for that relationship. The granularity attribute defines the lowest level of detail available in the cube for that dimension, which is generally the key attribute for the dimension. However, sometimes you may want to set the granularity of a particular cube dimension in a particular measure group to a different grain. For example, you may want to set the granularity attribute for the Time dimension to the Month attribute instead of to the Day attribute, if you are using a Sales Quotas or a Budget measure group. When you specify the granularity attribute to be an attribute other than the key attribute, you must guarantee that all other attributes in the dimension are directly or indirectly linked to this other attribute through attribute relationships. If not, Analysis Services will be unable to aggregate data correctly.

Define a Referenced Relationship and Referenced Relationship Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

A reference dimension relationship is defined on the **Dimension Usage** tab of Cube Designer. The reference dimension relationship is defined by specifying the following:

- The intermediate dimension to which to join. This can be a regular dimension or another reference dimension.
- A reference dimension attribute that defines the lowest level that the dimension is available for aggregation with regard to the measure group.
- The (foreign key) attribute in the intermediate dimension that corresponds to the reference dimension attribute.

Notice that the column that links the reference dimension to the fact table, which is generally the key attribute in the reference dimension, must also be defined as an attribute in the intermediate dimension. When you create a chain of reference dimensions, start by creating the regular relationship between the first dimension in the chain and the measure group. Then create each additional referenced relationship in order. A referenced relationship can only be made to a dimension that has an existing relationship to the measure group.

When you create a reference dimension relationship, the dimension attribute link is materialized by default. Materializing a dimension attribute link causes the value of the link between the fact table and the reference dimension for each row to be materialized, or stored, in the MOLAP structure for the dimension during processing. This will have a minor effect on processing performance and storage requirements, but will improve query performance.

In a reference dimension, granularity is specified by identifying the attribute that defines the relationship between a reference dimension and the measure group corresponding to the main table of the dimension. When multiple reference dimensions are chained together, the references define the relationship from the outermost dimension to the measure group.

Define a Fact Relationship and Fact Relationship Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

When you define a new cube dimension or a new measure group, Analysis Services will try to detect if a fact dimension relationship exists and then set the dimension usage setting to **Fact**. You can view or edit a fact dimension relationship on the **Dimension Usage** tab of Cube Designer. The fact relationship between a dimension and a measure group has the following constraints:

- A cube dimension can have only one fact relationship to a particular measure group.
- A cube dimension can have separate fact relationships to multiple measure groups.
- The granularity attribute for the relationship must be the key attribute (such as Transaction Number) for the dimension. This creates a one-to-one relationship between the dimension and facts in the fact table.

Define a Many-to-Many Relationship and Many-to-Many Relationship Properties

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

This topic explains many-to-many dimensions in Analysis Services, including when to use them and how to create them.

Introduction

Analysis Services supports many-to-many dimensions, allowing for more complex analytics than what can be described in a classic star schema. In a classic star schema, all dimensions have a one-to-many relationship with a fact table. Each fact joins to one dimension member; a single dimension member is associated with many facts.

Many-to-many removes this modeling restriction by enabling a fact (such as an account balance) to be associated with multiple members of the same dimension (the balance of a joint account can be attributed to two or more owners of a joint account).

Conceptually, a many-to-many dimensional relationship in Analysis Services is equivalent to many-to-many relationships in a relational model, supporting the same kinds of scenarios. Common examples of many-to-many include:

- Students are enrolled in many courses; each course has many students.
- Doctors have many patients; patients have many doctors.
- Customers have many bank accounts; bank accounts might belong to more than one customer.
- In Adventure Works, many customers have many reasons for ordering a product, and a sales reason can be associated with many orders.

Analytically, the problem that a many-to-many relationship solves is accurate representation of a count or sum relative to the dimensional relationship (usually by eliminating double-counts when performing calculations for a specific dimension member). An example is necessary to clarify this point. Consider a product or service that belongs to more than one category. If you were counting the number of services by category, you would want a service belonging to both categories to be included in each one. At the same time, you would not want to overstate the number of services that you provide. By specifying the many-to-many dimensional relationship, you are more likely to get the correct results back when querying by category or by service. However, thorough testing is always necessary to ensure that this is the case.

Structurally, creating a many-to-many dimensional relationship is similar to how you might create many-to-many in a relational data model. Whereas a relational model uses a *junction table* to store row associations, a multidimensional model uses an *intermediate measure group*. Intermediate measure group is the term we use to refer to a table that maps members from different dimensions.

Visually, a many-to-many dimensional relationship is not indicated in a cube diagram. Instead, use the Dimension Usage tab to quickly identify any many-to-many relationships in a model. A many-to-many relationship is indicated by the following icon.

Click the button to open the Define Relationship dialog box to verify the relationship type is many-to-many, and to

view which intermediate measure group is used in the relationship.

In subsequent sections, you will learn how to set up a many-to-many dimension and test model behaviors. If you would rather review additional information or try tutorials first, see **Learn More** at the end of this article.

Create a many-to-many dimension

A simple many-to-many relationship includes two dimensions having a many-to-many cardinality, an intermediate measure group for storing member associations, and a fact measure group containing measurable data, such as sum of total sales or the balance of a bank account.

Dimensions in a many-to-many relationship might have correspondent tables in the DSV, where each dimension in the model is based on an existing table in a data source. Conversely, the dimensions in your model might derive from fewer or different physical tables in the DSV. Using Sales Reasons and Sales Orders as a case in point, the Adventure Works sample cube demonstrates a many-to-many relationship using dimensions that exist as model-only data structures, without physical counterparts in the DSV. The Sales Order dimension is based on a fact table, rather than a dimension table, in the underlying data source.

The next procedure assumes that you already know which entities participate in the many-to-many relationship. See **Learn More** for further study.

To illustrate the steps used to create a many-to-many relationship, this procedure re-creates one of the many-to-many relationships in the Adventure Works sample cube. If you have the source data (that is, the Adventure Works sample data warehouse) installed on a relational database engine instance, you can follow these steps.

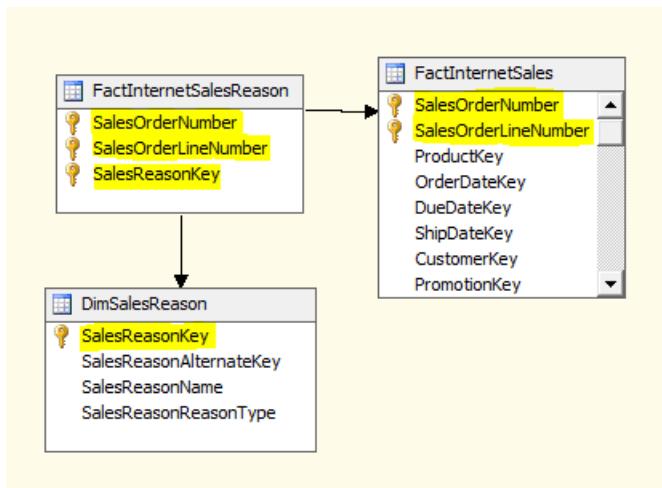

Step 1: Verify DSV relationships

1. In SQL Server Data Tools, in a multidimensional project, create a data source to the Adventure Works DW 2012 relational data warehouse, hosted on a SQL Server Database Engine instance.
2. Create a Data Source View using the following existing tables:
 - FactInternetSales
 - FactInternetSalesReason
 - DimSalesReason
3. Verify that all of the tables you plan to use in the many-to-many relationships are related in the DSV through primary key relationships. This is a requirement for establishing a link to the intermediate measure group in a subsequent step.

NOTE

If the underlying data source does not provide primary and foreign key relationships, you can create the relationships manually in the DSV. For more information, see [Define Logical Relationships in a Data Source View \(Analysis Services\)](#).

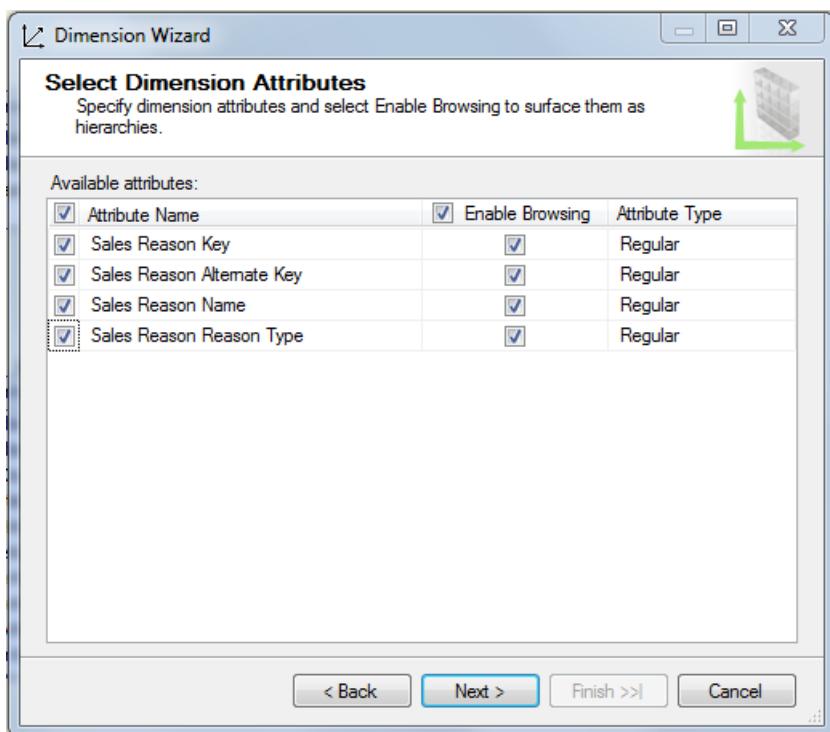

The following example confirms that the tables used in this procedure are linked using primary keys.

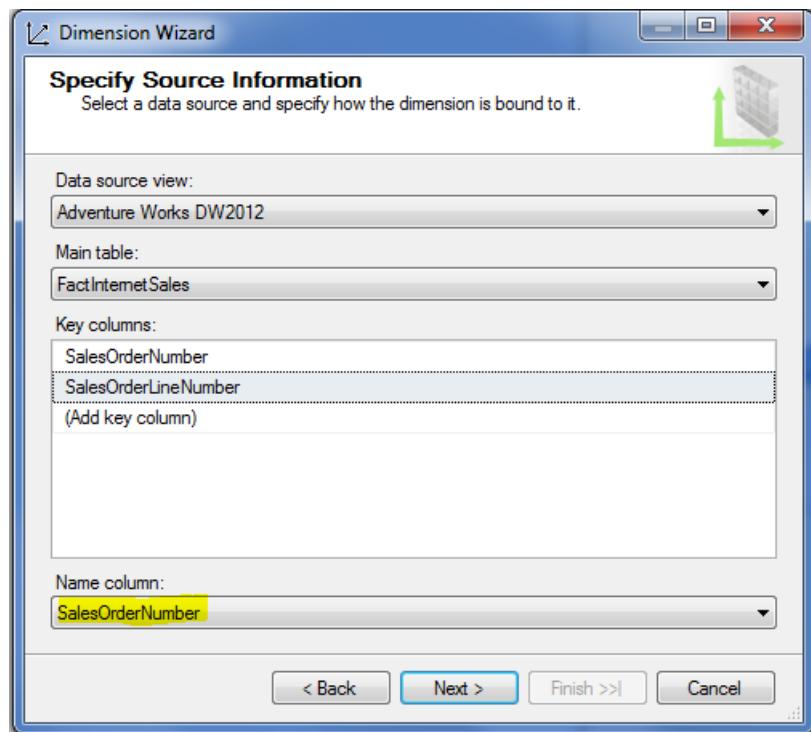

Step 2: Create dimensions and measure groups

1. In SQL Server Data Tools, in a multidimensional project, right-click **Dimensions** and select **New Dimension**.
2. Create a new dimension based on existing table, **DimSalesReason**. Accept all of the default values when specifying the source.

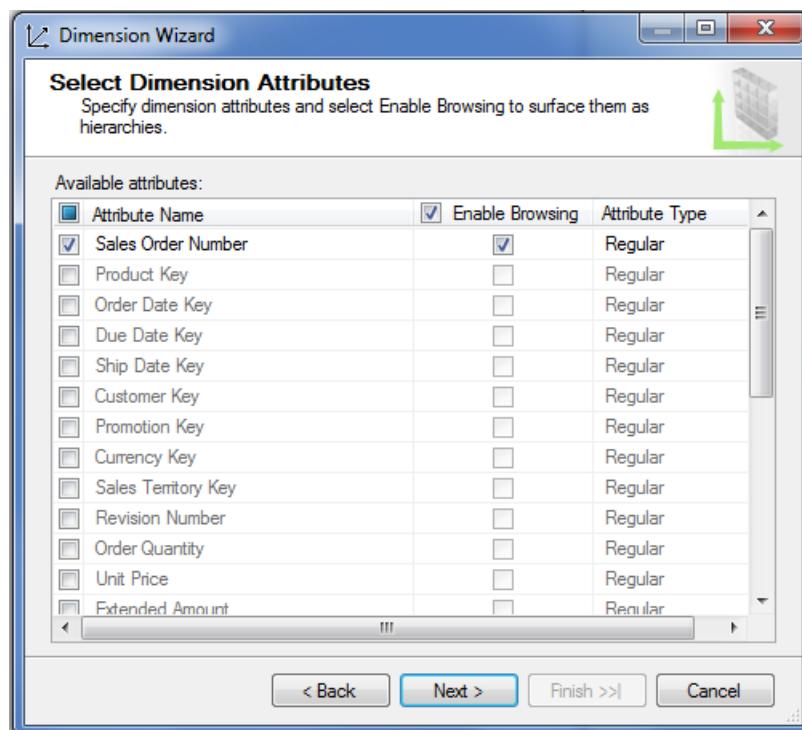

For attributes, select all.

3. Create a second dimension based on existing table, Fact Internet Sales. Although this is a fact table, it contains Sales Order information. We'll use it to build a Sales Order dimension.
4. In Specify Source Information, you will see a warning that indicates a Name column must be specified. Choose **SalesOrderNumber** as the Name.

5. On the next page of the wizard, choose the attributes. In this example, you can select just **SalesOrderNumber**.

6. Rename the dimension to **Dim Sales Orders**, so that you have a consistent naming convention for the dimensions.

Completing the Wizard
Type a name for the new dimension, verify the dimension structure, and then click Finish to save the dimension.

Name: Dim Sales Order

Preview:

- Dim Sales Order
 - Attributes
 - Sales Order Number

- Right-click **Cubes** and select **New Cube**.
- In measure group tables, choose **FactInternetSales** and **FactInternetSalesReason**.
You are choosing **FactInternetSales** because it contains the measures you want to use in the cube. You are choosing **FactInternetSalesReason** because it is the intermediate measure group, providing member association data that relates sales orders to sales reasons.
- Choose measures for each fact table.
To simplify your model, clear all the measures, and then select just **Sales Amount** and **Fact Internet Sales Count** at the bottom of the list. The **FactInternetSalesReason** only has one measure, so it is selected for you automatically.
- In the dimension list, you should see **Dim Sales Reason** and **Dim Sales Orders**.

In the Select New Dimensions page, the wizard prompts you to create a new dimension for **Fact Internet Sales Dimension**. You do not need this dimension, so you can clear it from the list.

- Name the cube and click **Finish**.

Step 3: Define Many-to-Many relationship

- In cube designer, click Dimension Usage tab. Notice that there is already a many-to-many relationship between **Dim Sales Reason** and **Fact Internet Sales**. Recall that the following icon indicates a many-to-many relationship.

- Click on the intersection cell between **Dim Sales Reason** and **Fact Internet Sales**, and then click the button to open the Define Relationship dialog box.

You can see that this dialog box is used to specify a many-to-many relationship. If you were adding dimensions that had a regular relationship instead, you would use this dialog box to change it to many-to-many.

- Deploy the project to an Analysis Services multidimensional instance. In the next step, you will browse the cube in Excel to verify its behaviors.

Testing Many-to-Many

When you define a many-to-many relationship in a cube, testing is imperative to ensure queries return expected results. You should test the cube using the client application tool that will be used by end-users. In this next procedure, you will use Excel to connect to the cube and verify query results.

Browse the cube in Excel

1. Deploy the project and then browse the cube to confirm the aggregations are valid.
2. In Excel, click **Data | From Other Sources | From Analysis Services**. Enter the name of the server, choose the database and cube.
3. Create a PivotTable that uses the following:
 - **Sales Amount** as the Value
 - **Sales Reason Name** on Columns
 - **Sales Order Number** on Rows

4. Analyze the results. Because we are using sample data, the initial impression is that all sales orders have identical values. However, if you scroll down, you begin to see data variation.

Part way down, you can find the sales amount and sales reasons for order number **SO5382**. Grand total of this particular order is **539.99**, and the purchase reasons attributed to this order include Promotion, Other and Price.

| | A | B | C | D | E | F | G | H | I |
|-------|--------------|--------------|--------------|--------|--------|---------|--------|------------|-------------|
| 1 | Sales Amount | Column Label | | | | | | | |
| 2 | Row Labels | Manufacturer | On Promotion | Other | Price | Quality | Review | Television | Grand Total |
| 11130 | SO53824 | | | | 63.5 | | | | 63.5 |
| 11131 | SO53825 | | 539.99 | 539.99 | 539.99 | | | | 539.99 |
| 11132 | SO53825 | | 8.99 | 8.99 | 8.99 | | | | 8.99 |
| 11133 | SO53825 | | 4.99 | 4.99 | 4.99 | | | | 4.99 |
| 11134 | SO53826 | | 539.99 | 539.99 | 539.99 | | | | 539.99 |
| 11135 | SO53826 | | 4.99 | 4.99 | 4.99 | | | | 4.99 |
| 11136 | SO53826 | | 8.99 | 8.99 | 8.99 | | | | 8.99 |

Notice that the Sales Amount is correctly calculated for the order; it is **539.99** for the entire order. Although **539.99** is indicated for each reason, that value is not summed for all three reasons, erroneously inflating our grand total.

Why put a sales amount under each sales reason in the first place? The answer is that it allows us to identify the amount of sales we can attribute to each reason.

5. Scroll to the bottom of the worksheet. It is now easy to see that Price is the most important reason for customer purchases, relative to other reasons as well as the grand total.

| Column Label | Manufacturer | On Promotion | Other | Price | Quality | Review | Television | Ad | Grand Total |
|--------------|-----------------|-----------------|---------------|------------------|-----------------|-----------------|--------------|------------------|-------------|
| | \$ 5,998,122.10 | \$ 6,361,828.95 | \$ 248,483.34 | \$ 10,975,842.56 | \$ 5,549,896.77 | \$ 1,694,881.98 | \$ 27,475.82 | \$ 29,358,677.22 | |

Tips for handling unexpected query results

1. Hide measures in the intermediate measure group, such as the count, that do not return meaningful results in a query. This prevents people from trying to use aggregations producing meaningless data. To hide a measure, set **Visibility** to **False** on the attribute in dimension designer.
2. Create perspectives to use a subset of measures and dimensions that support the analytical experience you want to provide. Possibly, a cube that contains many measure groups and dimensions do not work well together in all cases. By isolating the dimensions and measure groups that you intend to be used together, you ensure a more predictable outcome.
3. Always remember to deploy and reconnect after changing a model. In Excel, use the Refresh button on the PivotTable Analyze ribbon.
4. Avoid using linked measure groups in multiple many-to-many relationships, especially when those

relationships are in different cubes. Doing so can result in ambiguous aggregations. For more information, see [Incorrect Amounts for Linked Measures in Cubes containing Many-to-Many Relationships](#).

Measures and Measure Groups

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A cube includes *measures* in *measure groups*, business logic, plus a collection of dimensions that give context for evaluating the numerical data that a measure provides. Both measures and measure groups are an essential component of a cube. A cube cannot exist without at least one of each.

This topic describes [Measures](#) and [Measure Groups](#). It also contains the following table, with links to procedural steps for creating and configuring measures and measure groups.

| LINK | DESCRIPTION |
|---|--|
| Create Measures and Measure Groups in Multidimensional Models | Choose from one of several approaches for creating measures and measure groups. |
| Configure Measure Properties | If you used the Cube Wizard to start your cube, you might need to change the aggregation method, apply a data format, set the visibility of the measure in client applications, or possibly add a measure expression to manipulate the data before values are aggregated. |
| Configure Measure Group Properties | In a multidimensional model, a measure group equates to a fact table in the source data warehouse. Properties on a measure group allow you to specify caching behaviors, storage, and processing directives that operate collectively at the measure group level. Partition configuration is partly determined by the properties you set on measure group objects. |
| Use Aggregate Functions | Understand the aggregation methods that can be assigned to a measure. |
| Define Semiadditive Behavior | Semiadditive behavior refers to aggregations that are valid for some dimensions but not others. A common example is a bank account balance. You might want to aggregate balances by customer and region, but not time. For example, you would not want to add balances from the same account over consecutive days. To define semiadditive behavior, use the Add Business Intelligence Wizard. |
| Linked Measure Groups | Repurpose an existing measure group in other cubes in the same database or in different Analysis Services databases. |

Measures

A measure represents a column that contains quantifiable data, usually numeric, that can be aggregated. Measures represent some aspect of organizational activity, expressed in monetary terms (such as revenue, margins, or costs) or as counts (inventory levels, number of employees, customers, or orders), or as a more complex calculation that incorporates business logic.

Every cube must have at least one measure, but most have many, sometimes numbering in the hundreds. Structurally, a measure is often mapped to a source column in a fact table, with the column providing the values

used to load the measure. Alternatively, you can also define a measure using MDX.

Measures are context-sensitive, operating on numeric data in a context that is determined by whichever dimension members happen to be included in the query. For example, a measure that calculates **Reseller Sales** will be backed by a **Sum** operator, and it will add the sales amounts for each dimension member included in the query. Whether the query specifies individual products, rolls up to a category, or is sliced by time or geography, the measure should produce an operation that is valid for the dimensions included in the query.

In this example **Reseller Sales** aggregates to various levels along the **Sales Territory** hierarchy.

| Reseller Sales Amount | | Column Labels | | | | |
|-----------------------|--|----------------|-----------------|-----------------|-----------------|-----------------|
| Row Labels | | CY 2005 | CY 2006 | CY 2007 | CY 2008 | Grand Total |
| Europe | | \$1,698,880.94 | \$5,632,816.55 | \$3,538,837.31 | \$10,870,534.80 | |
| North America | | \$8,065,435.31 | \$22,445,548.71 | \$25,722,421.91 | \$11,752,320.88 | \$67,985,726.81 |
| Canada | | \$1,513,359.46 | \$4,822,999.20 | \$5,651,305.43 | \$2,390,261.51 | \$14,377,925.60 |
| United States | | \$6,552,075.85 | \$17,622,549.51 | \$20,071,116.48 | \$9,362,059.37 | \$53,607,801.21 |
| Central | | \$951,240.65 | \$2,625,639.72 | \$3,005,591.43 | \$1,323,536.38 | \$7,906,008.18 |
| Northeast | | \$568,545.52 | \$2,443,901.73 | \$2,863,937.85 | \$1,056,456.93 | \$6,932,842.01 |
| Northwest | | \$1,689,790.14 | \$3,471,099.54 | \$4,640,535.06 | \$2,633,651.25 | \$12,435,076.00 |
| Southeast | | \$1,448,921.51 | \$2,815,903.10 | \$2,429,279.90 | \$1,173,311.72 | \$7,867,416.23 |
| Southwest | | \$1,893,578.02 | \$6,266,005.43 | \$7,131,772.25 | \$3,175,103.09 | \$18,466,458.79 |
| Pacific | | | | \$847,430.96 | \$746,904.41 | \$1,594,335.38 |
| Grand Total | | \$8,065,435.31 | \$24,144,429.65 | \$32,202,669.43 | \$16,038,062.60 | \$80,450,596.98 |

Measures produce valid results when the fact table that contains the numeric source data also contains pointers to dimension tables that are used in the query. Using the Reseller Sales example, if each row storing a sales amount also stores a pointer to a product table, a date table, or a sales territory table, then queries that include members from those dimension will resolve correctly.

What happens if the measure is unrelated to the dimensions used in query? Typically, Analysis Services will show the default measure, and the value will be the same for all members. In this example, **Internet Sales**, which measure direct sales placed by customers using the online catalog, has no relationship to the sales organization.

| Internet Sales Amount | | Column Labels | | | | |
|--------------------------|--|---------------|----------------|----------------|-----------------|-------------|
| Row Labels | | CY 2010 | CY 2011 | CY 2012 | CY 2013 | CY 2014 |
| AdventureWorks Cycle | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| European Operations | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| France | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Germany | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| North America Operations | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Canadian Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| USA Operations | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Central Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Northeast Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Northwest Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Southeast Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Southwest Division | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Pacific Operations | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |
| Grand Total | | \$43,421.04 | \$7,075,525.93 | \$5,842,485.20 | \$16,351,550.34 | \$45,694.72 |

To minimize the chances of encountering these behaviors in a client application, you could build multiple cubes or perspectives within the same database, and ensure that each cube or perspective contains only related objects. The relationships you need to check are between the measure group (mapped to the fact table) and the dimensions.

Measure Groups

In a cube, measures are grouped by their underlying fact tables into measure groups. Measure groups are used to associate dimensions with measures. Measure groups are also used for measures that have distinct count as their

aggregation behavior. Placing each distinct count measure into its own measure group optimizes aggregation processing.

A simple [MeasureGroup](#) object is composed of basic information like the group name, storage mode, and processing mode. It also contains its constituent parts; the measures, dimensions, and partitions that form the composition of the measure group.

Create Measures and Measure Groups in Multidimensional Models

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A *measure* is an aggregation of numeric data values, such as sum, count, minimum, maximum, average, or a custom MDX expression that you create. A *measure group* is a container for one or more measures. All measures exist in a measure group, even if there is only one measure. A cube must have at least one measure and measure group.

This topic includes the following sections:

- [Approaches for creating measures](#)
- [Components of a measure](#)
- [Modeling measures and measure groups on facts and fact tables](#)
- [Granularity of a measure group](#)

Approaches for creating measures

Measures can be a static element of the cube, created at design time, always present whenever the cube is accessed. But you can also define a measure as a *calculated member* by using a MDX to provide a calculated value for a measure based on other measures in the cube. A calculated member can be scoped to session or user.

To create a measure or a measure group, use one of these approaches:

| | |
|--------------------|--|
| Cube Wizard | <p>Run the Cube Wizard in Visual Studio with Analysis Services projects to create a cube.</p> <p>In Solution Explorer, right-click Cubes and choose New Cube. See Multidimensional Modeling (Adventure Works Tutorial) if you need help with these steps.</p> <p>When you create a cube based on tables from an existing data warehouse, definitions for the measures and measure group materialize as part of the cube creation process. In the wizard, you'll choose which facts and fact tables to use as the basis for the measure and measure group objects in your cube.</p> |
| New Measure dialog | <p>Assuming the cube already exists in Visual Studio with Analysis Services projects, double-click the cube name in Solution Explorer to open it in Cube Designer. In the Measures pane, right-click the top node to create a new measure group, or new measures, by specifying a source table, column, and aggregation type. Using this approach requires that you choose the aggregation method from a fixed list of prebuilt functions. See Use Aggregate Functions for a discussion of the more commonly used aggregations.</p> |

| | |
|-------------------|--|
| Calculated member | <p>Calculated members add flexibility and analysis capability to a cube in Analysis Services because you can control when and how they are created. Sometimes you only need a measure temporarily, for the duration of a user session, or in Management Studio as part of an investigation.</p> <p>In Visual Studio with Analysis Services projects, open the Calculations tab to create a new calculated member.</p> <p>Choose this approach when basing a measure on an MDX expression. See these topics for more information: Building Measures in MDX, Calculations, Calculations in Multidimensional Models and MDX Scripting Fundamentals (Analysis Services).</p> |
| MDX or XMLA | <p>In SQL Server Management Studio, you can execute MDX or XMLA to alter a database to include a new calculated measure. This approach is useful for ad hoc testing of data, after the solution is deployed to a server. See Document and Script an Analysis Services Database.</p> |

Components of a measure

A measure is an object with properties. In addition to its name, a measure must have an aggregation type and a source column or an expression used to load the measure with data. You can modify the measure definition by setting its properties.

| | |
|--------------------|--|
| source | <p>Most measures come from numeric columns in fact tables in an external data warehouse, such as the Sales Amount column in the Internet Sales and Reseller Sales tables in the AdventureWorks data warehouse, but you can also create new measures based entirely on calculations that you define.</p> <p>Attribute columns from dimension tables can be used to define measures, but such measures are typically semiadditive or nonadditive in terms of their aggregation behavior. For more information about semiadditive behavior, see Define Semiadditive Behavior.</p> |
| aggregation | <p>By default, measures are summed along each dimension. However, the AggregateFunction property lets you modify this behavior. See Use Aggregate Functions for a list.</p> |
| Properties | <p>See Configure Measure Properties for additional property descriptions.</p> |

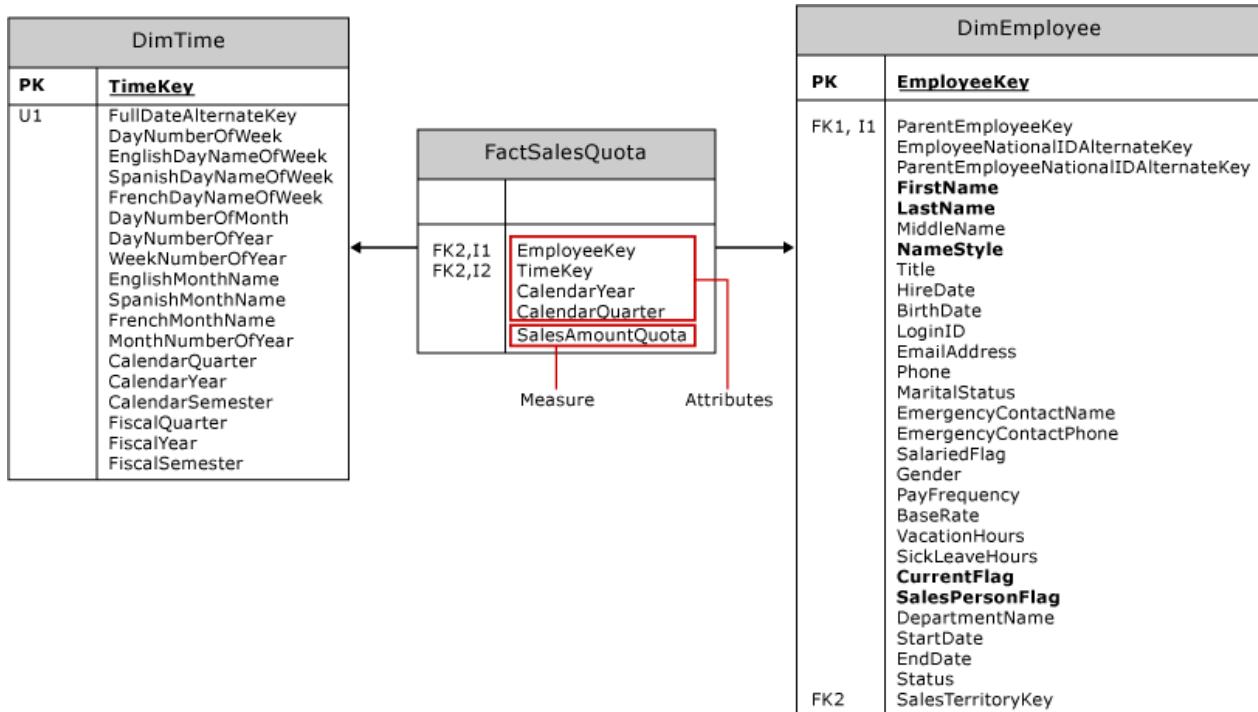

Modeling measures and measure groups on facts and fact tables

Before you run a wizard, it helps to understand the modeling principles behind measure definition.

Measures and measure groups are the multidimensional objects that represent facts and fact tables in an external data warehouse. In most cases, measures and measure groups will be based on objects in a data source view, which in turn are created from the underlying data warehouse.

The following diagram represents the **FactSalesQuota** fact table and the two dimension tables associated with it, **DimTime** and **DimEmployee**. In the Adventure Works sample cube, these tables are used as the basis of the

Sales Quotas measure group, and the Time and Employee dimensions.

The fact table contains two basic types of columns: attribute columns and measure columns.

- Attribute columns are used to create foreign key relationships to dimension tables, so that the quantifiable data in the measure columns can be organized by the data contained in the dimension tables. Attribute columns are also used to define the granularity of a fact table and its measure group.
- Measure columns define the measures contained by a measure group.

When you run the Cube Wizard, the foreign keys are filtered out. In the list of remaining columns to choose from, you will see measure columns, plus attribute columns that are not identified as a foreign key. In the **FactSalesQuota** example, the wizard will offer **CalendarYear** and **CalendarQuarter** in addition to **SalesAmountQuota**. Only the **SalesAmountQuota** measure column will result in a workable measure for your multidimensional model. The other date-based columns exist to qualify each quota amount. You should exclude the other columns, **CalendarYear** and **CalendarQuarter**, from the measure list in the Cube Wizard (or remove them from the measure group later in the designer).

The point to take away from this discussion is that not all columns offered by the wizard are useful as a measure. Rely on your understanding of the data and how it will be used when deciding which columns to use as measures. Remember that you can right-click a table in the data source view to explore the data, which can help you identify which columns to use as measures. See [Explore Data in a Data Source View \(Analysis Services\)](#) for more information.

NOTE

Not all measures are derived directly from a value stored in a column of the fact table. For example, the **Sales Person Count** measure defined in the **Sales Quota** measure group of the Adventure Works sample cube is actually based on the count of unique values (or distinct count) in the **EmployeeKey** column of the **FactSalesQuota** fact table.

Granularity of a measure group

Measure groups have an associated granularity that refers to the level of detail supported by a fact table. The granularity is set through the foreign key relationship to a dimension.

For example, the **FactSalesQuota** fact table has a foreign key relationship with the **DimEmployee** table, each

record in the **FactSalesQuota** table is related to a single employee, and thus the granularity of the measure group as viewed from the Employee dimension is at the individual employee level.

The granularity of a measure group can never be set finer than the lowest level of the dimension from which the measure group is viewed, but the granularity can be made coarser by using additional attributes. For example, the **FactSalesQuota** fact table uses three columns, **TimeKey**, **CalendarYear**, and **CalendarQuarter**, to establish the granularity of the relationship with the **DimTime** table. As a result, the granularity of the measure group as viewed from the Time dimension is by calendar quarter, and not by day, which is the lowest level of the Time dimension.

You can specify the granularity of a measure group with relation to a specific dimension by using the **Dimension Usage** tab of the Cube Designer. For more information about dimension relationships, see [Dimension Relationships](#).

Configure Measure Group Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Measures groups have properties that enable you to define how measure groups function.

Measure Group Properties

Measure group properties determine behaviors for the entire measure group and set the default behaviors for certain properties of measures within a measure group.

| PROPERTY | DEFINITION |
|----------------------------------|--|
| AggregationPrefix | Applies to ROLAP storage. Assigns a common prefix to the indexed views in SQL Server, used to store aggregations for the partitions associated with this measure group. |
| DataAggregation | This property is reserved for future use and currently has no effect. Therefore, it is recommended that you do not modify this setting. |
| Description | You can use this property to document the measure group. |
| ErrorConfiguration | Configurable error handling settings for handling of duplicate keys, unknown keys, null keys, error limits, action upon error detection, and the error log file. See Error Configuration for Cube, Partition, and Dimension Processing (SSAS - Multidimensional) . |
| EstimatedRows | Specifies the estimated number of rows in the fact table. |
| EstimatedSize | Specifies the estimated size (in bytes) of the measure group. |
| ID | Specifies the identifier of the object. |
| IgnoreUnrelatedDimensions | Determines whether unrelated dimensions are forced to their top level when members of dimensions that are unrelated to the measure group are included in a query. Default setting is True . |
| Name | Name of the measure. This property is read-only. |
| ProactiveCaching | Configurable error handling settings for handling of duplicate keys, unknown keys, null keys, error limits, action upon error detection, and the error log file. |
| ProcessingMode | Indicates whether indexing and aggregating should occur during or after processing. Options are Regular and LazyAggregations. LazyAggregations can be used to run aggregation as a background task. |

| PROPERTY | DEFINITION |
|---------------------------|--|
| ProcessingPriority | Determines the processing priority of the cube during background operations, such as lazy aggregations and indexing. The default value is 0 . |
| StorageLocation | The file system storage location for the measure group. If none is specified, the location is inherited from the cube that contains the measure group. |
| StorageMode | The storage mode for the measure group. Available values are MOLAP, ROLAP, or HOLAP. |
| Type | Specifies the type of the measure group. |

Configure Measure Properties

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Measures have properties that enable you to define how the measures function and to control how the measures appear to users.

You can set properties in Visual Studio with Analysis Services projects when creating or editing a cube or measure. You can also set them programmatically, using MDX or AMO. See [Create Measures and Measure Groups in Multidimensional Models](#) or [CREATE MEMBER Statement \(MDX\)](#) or [Programming AMO OLAP Basic Objects](#) for details.

Measure Properties

Measures inherit certain properties from the measure group of which they are a member, unless those properties are overridden at the measure level. Measure properties determine how a measure is aggregated, its data type, the name that is displayed to the user, the display folder in which the measure will appear, its format string, any measure expression, the underlying source column, and its visibility to users.

| PROPERTY | DEFINITION |
|--------------------------|---|
| AggregateFunction | Required. Determines how measures are aggregated. Sum is the default aggregation. For more information, see Use Aggregate Functions for a description of each function. |
| DataType | Required. Specifies the data type of the column in the underlying fact table to which the measure is bound. This value is inherited from the source column by default. |
| Description | Provides a description of the measure, which may be exposed in client applications. |
| DisplayFolder | Specifies the folder in which the measure will appear when users connect to the cube. When a cube has many measures, you can use display folders to categorize the measures and improve the user browsing experience. |
| FormatString | You can select the format that is used to display measure values to users by using the FormatString property of the measure.

Although a list of display formats is provided in Visual Studio with Analysis Services projects, you can specify many additional formats that are not in the list. You can specify any named or user-defined format that is valid in Microsoft Visual Basic. |
| ID | Required. Displays the unique identifier (ID) of the measure. This property is read-only. |

| PROPERTY | DEFINITION |
|--------------------------|--|
| MeasureExpression | Specifies a constrained MDX expression defining the value of the measure. The expression is evaluated at the leaf level before being aggregated, and allows for weighting of a value. For example, in currency conversion where a sales amount is weighted by the exchange rate. |
| Name | Required. Specifies the name of the measure. |
| Source | Required. Specifies the column in the data source view to which the measure is bound. See Data Sources and Bindings (SSAS Multidimensional) . |
| Visible | Determines the visibility of the measure in client applications. |

[Modifying Measures](#)

Use Aggregate Functions

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When a dimension is used to slice a measure, the measure is summarized along the hierarchies contained in that dimension. The summation behavior depends on the aggregate function specified for the measure. For most measures containing numeric data, the aggregate function is **Sum**. The value of the measure will sum to different amounts depending on which level of the hierarchy is active.

In Analysis Services, every measure that you create is backed by an aggregation function that determines the measure's operation. Predefined aggregation types include **Sum**, **Min**, **Max**, **Count**, **Distinct Count**, and several other more specialized functions. Alternatively, if you require aggregations based on complex or custom formulas, you can build an MDX calculation in lieu of using a prebuilt aggregation function. For example, if you want to define a measure for a percentage value, you would do that in MDX, using a calculated measure. See [CREATE MEMBER Statement \(MDX\)](#).

Measures that are created via the Cube Wizard are assigned an aggregation type as part of the measure definition. The aggregation type is always **Sum**, assuming the source column contains numeric data. **Sum** is assigned regardless of the source column's data type. For example, if you used the Cube Wizard to create measures, and you pulled in all columns from a fact table, you will notice that all of the resulting measures have an aggregation of **Sum**, even if the source is a date time column. Always review the pre-assigned aggregation methods for measures created via the wizard to make sure the aggregation function is suitable.

You can assign or change the aggregation method in either the cube definition, via SQL Server Data Tools - Business Intelligence, or via MDX. See [Create Measures and Measure Groups in Multidimensional Models](#) or [Aggregate \(MDX\)](#) for further instructions.

Aggregate Functions

Analysis Services provides functions to aggregate measures along the dimensions that are contained in measure groups. The *additivity* of an aggregation function determines how the measure is aggregated across all the dimensions in the cube. Aggregation functions fall into three levels of additivity:

Additive

An additive measure, also called a fully additive measure, can be aggregated along all the dimensions that are included in the measure group that contains the measure, without restriction.

Semiadditive

A semiadditive measure can be aggregated along some, but not all, dimensions that are included in the measure group that contains the measure. For example, a measure that represents the quantity available for inventory can be aggregated along a geography dimension to produce a total quantity available for all warehouses, but the measure cannot be aggregated along a time dimension because the measure represents a periodic snapshot of quantities available. Aggregating such a measure along a time dimension would produce incorrect results. See [Define Semiadditive Behavior](#) for details.

Nonadditive

A nonadditive measure cannot be aggregated along any dimension in the measure group that contains the measure. Instead, the measure must be individually calculated for each cell in the cube that represents the measure. For example, a calculated measure that returns a percentage, such as profit margin, cannot be aggregated from the percentage values of child members in any dimension.

The following table lists the aggregation functions in Analysis Services, and describes both the additivity and expected output of the function.

| AGGREGATION FUNCTION | ADDITIVITY | RETURNED VALUE |
|--------------------------|--------------|--|
| Sum | Additive | Calculates the sum of values for all child members. This is the default aggregation function. |
| Count | Additive | Retrieves the count of all child members. |
| Min | Semiadditive | Retrieves the lowest value for all child members. |
| Max | Semiadditive | Retrieves the highest value for all child members. |
| DistinctCount | Nonadditive | Retrieves the count of all unique child members. For more details, see About Distinct Count Measures in the next section. |
| None | Nonadditive | No aggregation is performed, and all values for leaf and nonleaf members in a dimension are supplied directly from the fact table for the measure group that contains the measure. If no value can be read from the fact table for a member, the value for that member is set to null. |
| ByAccount | Semiadditive | <p>Calculates the aggregation according to the aggregation function assigned to the account type for a member in an account dimension. If no account type dimension exists in the measure group, treated as the None aggregation function.</p> <p>For more information about account dimensions, see Create a Finance Account of parent-child type Dimension.</p> |
| AverageOfChildren | Semiadditive | Calculates the average of values for all non-empty child members. |
| FirstChild | Semiadditive | Retrieves the value of the first child member. |
| LastChild | Semiadditive | Retrieves the value of the last child member. |
| FirstNonEmpty | Semiadditive | Retrieves the value of the first non-empty child member. |

| AGGREGATION FUNCTION | ADDITIVITY | RETURNED VALUE |
|----------------------|--------------|---|
| LastNonEmpty | Semiadditive | Retrieves the value of the last non-empty child member. |

About Distinct Count Measures

A measure with an **Aggregate Function** property value of **Distinct Count** is called a distinct count measure. A distinct count measure can be used to count occurrences of a dimension's lowest-level members in the fact table. Because the count is distinct, if a member occurs multiple times, it is counted only once. A distinct count measure is always placed in a dedicated measure group. Putting a distinct count measure into its own measure group is a best practice that has been built into the designer as a performance optimization technique.

Distinct count measures are commonly used to determine for each member of a dimension how many distinct, lowest-level members of another dimension share rows in the fact table. For example, in a Sales cube, for each customer and customer group, how many distinct products were purchased? (That is, for each member of the Customers dimension, how many distinct, lowest-level members of the Products dimension share rows in the fact table?) Or, for example, in an Internet Site Visits cube, for each site visitor and site visitor group, how many distinct pages on the Internet site were visited? (That is, for each member of the Site Visitors dimension, how many distinct, lowest-level members of the Pages dimension share rows in the fact table?) In each of these examples, the second dimension's lowest-level members are counted by a distinct count measure.

This kind of analysis need not be limited to two dimensions. In fact, a distinct count measure can be separated and sliced by any combination of dimensions in the cube, including the dimension that contains the counted members.

A distinct count measure that counts members is based on a foreign key column in the fact table. (That is, the measure's **Source Column** property identifies this column.) This column joins the dimension table column that identifies the members counted by the distinct count measure.

[Define Semiadditive Behavior](#)

Define Semiadditive Behavior

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Semiadditive measures, which do not uniformly aggregate across all dimensions, are very common in many business scenarios. Every cube that is based on snapshots of balances over time exhibits this problem. You can find these snapshots in applications dealing with securities, account balances, budgeting, human resources, insurance policies and claims, and many other business domains.

Add semiadditive behavior to a cube to define an aggregation method for individual measures or members of the account type attribute. If the cube contains an account dimension, you can automatically set semiadditive behavior based on the account type.

To add semiadditive behavior, open a cube in Cube Designer and choose **Add Business Intelligence** from the Cube menu. In the Business Intelligence Wizard, select the **Define semiadditive behavior** option on the **Choose Enhancement** page. This wizard then guides you through the steps of identifying which measures have semiadditive behavior.

With the exception of LastChild which is available in the standard edition, semi-additive behaviors are only available in the business intelligence or enterprise editions.

Define Semiadditive Behavior

On the **Define Semiadditive Behavior** page of the wizard, you select how to define semiadditivity by selecting one of the following options:

Turn off semiadditive behavior

Removes semiadditive behavior from a cube in which semiadditive behavior was previously defined. This selection resets a measure to **SUM** if it is set to any of the following aggregation function types:

- By Account
- Average of Children
- First Child
- Last Child
- Last Nonempty Child
- First Nonempty Child
- None

This option does not change measures with a regular aggregation function: **Sum**, **Min**, **Max**, **Count**, or **Distinct****Count**.

The wizard has detected the 'Account' account dimension, which contains semiadditive members. The server will aggregate members of this dimension according to the semiadditive behavior specified for each account type.

Causes the system to set all measures from a measure group dimensioned by an Account type dimension to the By Account aggregation function and the server will aggregate members of the dimension according to the semiadditive behavior specified for each account type.

NOTE

This option is selected by default if the wizard detects an Account type dimension.

Define semiadditive behavior for individual measures

Selects the semiadditive behavior of each measure individually. The default setting is **SUM** (fully additive).

NOTE

This option is selected by default if the wizard does not detect an Account type dimension.

For each measure, you can select from the types of semiadditive functionality described in the following table.

| SEMIADDITIVE FUNCTION | DESCRIPTION |
|-----------------------|--|
| Average of Children | The aggregation of a member is the average of its children. |
| ByAccount | The system reads the semiadditive behavior specified for the account type. |
| Count | The aggregation is a count of members. |
| Distinct Count | The aggregation is a count of unique members. |
| First Child | The member value is evaluated as the value of its first child along the time dimension. |
| FirstNonEmpty | The member value is evaluated as the value of its first child along the time dimension that contains data. |
| LastChild | The member value is evaluated as the value of its last child along the time dimension. |
| LastNonEmpty | The member value is evaluated as the value of its last child along the time dimension that contains data. |
| Max | The standard maximum aggregation function is applied. |
| Min | The standard minimum aggregation function is applied. |
| None | No aggregation is applied. |
| Sum | The standard summation function is applied. |

Any existing semiadditive behavior is overwritten when you complete the wizard.

Linked Measure Groups

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A linked measure group is based on another measure group in a different cube within the same database or a different Analysis Services database. You might use a linked measure group if you want to reuse a set of measures, and the corresponding data values, in multiple cubes.

Microsoft recommends that the original and linked measure groups reside in solutions that run on the same server. Linking to a measure group on a remote server is scheduled for deprecation in a future release.

IMPORTANT

Linked measure groups are read-only. To pick up the latest changes, you must delete and recreate all linked measure groups based on the modified source object. For this reason, copy and pasting measure groups between projects is an alternative approach that you should consider in case future modifications to the measure group are required.

Usage Limitations

As noted previously, an important constraint to using linked measures is an inability to customize a linked measure directly. Modifications to the data type, format, data binding, and visibility, as well as membership of the items in the measure group itself, are all changes that must be made in the original measure group.

Operationally, linked measure groups are identical to other measure groups when accessed by client applications, and are queried in the same manner as other measure groups.

When you query a cube that contains a linked measure group, the link is established and resolved during the first calculation pass of the destination cube. Because of this behavior, any calculations that are stored in the linked measure group cannot be resolved before the query is evaluated. In other words, calculated measures and calculated cells must be recreated in the destination cube rather than inherited from the source cube.

The following list summarizes usage limitations.

- You cannot create a linked measure group from another linked measure group.
- You cannot add or remove measures in a linked measure group. Membership is defined only in the original measure group.
- Writeback is not supported in linked measure groups.
- Linked measure groups cannot be used in multiple many-to-many relationships, especially when those relationships are in different cubes. Doing so can result in ambiguous aggregations. For more information, see [Incorrect Amounts for Linked Measures in Cubes containing Many-to-Many Relationships](#).

The measures contained in a linked measure group can be directly organized only along linked dimensions retrieved from the same Analysis Services database. However, you can use calculated members to relate information from linked measure groups to the other, non-linked dimensions in your cube. You can also use an indirect relationship, such as a reference or many-to-many relationship, to relate non-linked dimensions to a linked measure group.

Create or modify a linked measure

Use Visual Studio with Analysis Services projects to create a linked measure group.

1. Finalize any modifications to the original measure group now, in the source cube, so that you don't have to recreate the linked measure groups later in subsequent cubes. You can rename a linked object, but you cannot change any other properties.
2. In Solution Explorer, double-click the cube to which you are adding the linked measure group. This step opens the cube in Cube Designer.
3. In Cube Designer, in either the Measures pane or Dimensions pane, right-click anywhere in either pane, then select **New Linked Object**. This starts the Linked Object Wizard.
4. On the first page, specify the data source. This step establishes the location of the original measure group. The default is the current cube in the current database, but you can also choose a different Analysis Services database.
5. On the next page, choose the measure group or dimension you want to link. Dimensions and Cube objects, such as measure groups, are listed separately. Only those objects not already present in the current cube are available.
6. Click **Finish** to create the linked object. Linked objects appear in the Measures and Dimensions pane, indicated by the link icon.

Secure a linked measure

After the link has been defined, access to the measures in a linked measure group, is managed in the same manner as access to other measure groups. A linked object appears alongside its non-linked counterparts in Role Designer. For more information on managing security for a measure group, see [Grant cube or model permissions \(Analysis Services\)](#).

In order to define or use a linked measure group, the Windows service account for the Analysis Services instance must belong to an Analysis Services database role that has **ReadDefinition** and **Read** access rights on the source Analysis Services instance to the source cube and measure group, or must belong to the Analysis Services Administrators role for the source Analysis Services instance.

Partitions in Multidimensional Models

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

In Analysis Services, a *partition* provides the physical storage of fact data loaded into a measure group. A single partition is created for each measure group automatically, but it is common to create additional partitions that further segment the data, resulting in more efficient processing and faster query performance.

Processing is more efficient because partitions can be processed independently and in parallel, on one or more servers. Queries run faster because each partition can be configured to have storage modes and aggregation optimizations that result in shorter response times. For example, choosing MOLAP storage for partitions containing newer data is typically faster than ROLAP. Likewise, if you partition by date, partitions containing newer data can have more optimizations than partitions containing older data that is accessed less frequently. Note that varying storage and aggregation design by partition will have a negative impact on future merge operations. Be sure to consider whether merging is an essential component of your partition management strategy before optimizing individual partitions.

NOTE

Support for multiple partitions is available in the business intelligence edition and enterprise edition. The standard edition does not support multiple partitions. For more information, see [Features Supported by the Editions of SQL Server 2016](#).

Important considerations when designing a partitioning strategy

The integrity of a cube's data relies on the data being distributed among the partitions of the cube such that no data is duplicated among the partitions. When data is summarized from the partitions, any data elements that are present in more than one partition will be summarized as if they were different data elements. This can result in incorrect summaries and erroneous data provided to the end user. For example, if a sales transaction for Product X is duplicated in the fact tables for two partitions, summaries of Product X sales can include a double accounting of the duplicated transaction.

Partitions can be merged; you can use this feature in your overall storage and data update strategy. Partitions can be merged only if they have the same storage mode and aggregation design. To create partitions that are candidates for later merging, you can copy the aggregation design of another partition when you create partitions. You can also edit a partition after it has been created to copy the aggregation design of another partition. Merging partitions must also be performed carefully to avoid duplication of data in the resulting partition, which can cause cube data to be inaccurate.

Local Partitions

Local partitions are partitions that are defined, processed, and stored on one server. If you have large measure groups in a cube, you might want to partition them out so that processing occurs in parallel across the partitions. The advantage is that parallel processing provides faster execution. Because one partition processing job does not have to finish before another starts, they can run in parallel. For more information, see [Create and Manage a Local Partition \(Analysis Services\)](#).

Remote Partitions

Remote partitions are partitions that are defined on one server, but are processed and stored on another. If you

want to distribute storage of your data and metadata across multiple servers, use remote partitions. Ordinarily, when you transition from development to production, the size of data under analysis grows several times over. With such large chunks of data, one possible alternative is to distribute that data over multiple computers. This is not just because one computer cannot hold all the data, but because you will want more than one computer processing the data in parallel. For more information, see [Create and Manage a Remote Partition \(Analysis Services\)](#).

Aggregations

Aggregations are precalculated summaries of cube data that help enable Analysis Services to provide rapid query responses. You can control the number of aggregations created for a measure group by setting limits on storage, performance gains, or arbitrarily stopping the aggregation build process after it has been running for a while. More aggregations are not necessarily better. Every new aggregation comes at a cost, both in terms of disk space and processing time. We recommend creating aggregations for a thirty percent performance gain, and then raising the number only if testing or experience warrants it. For more information, see [Designing Aggregations \(Analysis Services - Multidimensional\)](#).

Partition Merging and Editing

If two partitions use the same aggregation design, you can merge those two partitions into one. For example, if you have an inventory dimension that is partitioned by month, then at the end of each calendar month, you can merge that month partition with the existing year-to-date partition. This way, the current month partition can be processed and analyzed quickly, while the rest of the year in months only has to be reprocessed when merged. That reprocess requires longer processing time, and can be run less frequently. For more information about managing the partition merging process, see [Merge Partitions in Analysis Services \(SSAS - Multidimensional\)](#). To edit cube partitions by using the **Partitions** tab in Cube Designer, see [Edit or Delete Partitions \(Analysis Services - Multidimensional\)](#).

Create and Manage a Local Partition (Analysis Services)

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can create additional partitions for a measure group to improve processing performance. Having multiple partitions allows you to allocate fact data across a corresponding number of physical data files on local as well as remote servers. In Analysis Services, partitions can be processed independently and in parallel, giving you more control over processing workloads on the server.

Partitions can be created in Visual Studio with Analysis Services projects during model design, or after the solution is deployed using SQL Server Management Studio or XMLA. We recommend that you choose one approach only. If you alternate between tools, you might find that changes made to a deployed database in SQL Server Management Studio are overwritten when you subsequently redeploy the solution from Visual Studio with Analysis Services projects.

Before you start

Check whether you have either the business intelligence edition or enterprise edition. Standard edition does not support multiple partitions. To check the edition, right-click the server node in SQL Server Management Studio and choose **Reports | General**. For more information about feature availability, see [Features Supported by the Editions of SQL Server 2016](#).

From the outset, it's important to understand that partitions must share the same aggregation design if you want to merge them later. Partitions can be merged only if they have identical aggregation designs and storage modes.

TIP

Explore the data in Data Source View (DSV) to understand the range and depth of the data you are partitioning. For example, if partitioning by date, you can sort on a date column to determine the upper and lower bounds of each partition.

Choose an approach

The most important consideration when creating partitions is to segment the data so that there are no duplicate rows. Data must be stored in one, and only one, partition to avoid double counting any rows. As such, it's common to partition by DATE so that you can define clear boundaries between each partition.

You can use either technique to distribute the fact data across multiple partitions. The following techniques can be used to segment the data.

TECHNIQUE

RECOMMENDATIONS

| TECHNIQUE | RECOMMENDATIONS |
|--|---|
| Use SQL queries to segment fact data | <p>Partitions can be sourced from SQL queries. During processing, the SQL query is to retrieve the data. The query's WHERE clause provides the filter that segments the data for each partition. Analysis Services generates the query for you, but you must fill in the WHERE clause to properly segment the data.</p> <p>The primary advantage of this approach is the ease with which you can partition data from a single source table. If all of the source data originates from a large fact table, you can build queries that filter that data into discrete partitions, without having to create additional data structures in the Data Source View (DSV).</p> <p>One disadvantage is that using queries will break the binding between the partition and the DSV. If you later update the DSV in the Analysis Services project, such as adding columns to the fact table, you must manually edit the queries for each partition to include the new column. The second approach, discussed next, does not have this disadvantage.</p> |
| Use tables in the DSV to segment fact data | <p>You can bind a partition to a table, named query, or view in the DSV. As the basis of a partition, all three are functionally equivalent. The entire table, named query, or view provides all of the data to a single partition.</p> <p>Using a table, view, or named query places all of the data selection logic in the DSV, which can be easier to manage and maintain over time. An important advantage to this approach is that table bindings are preserved. If you update the source table later, you do not have to modify the partitions that use it. Secondly, all of the tables, named queries and views exist in a common work space, making updates more convenient than having to open and edit partition queries individually.</p> |

Option 1: Filter a Fact Table for Multiple Partitions

To create multiple partitions, you begin by modifying the **Source** property of the default partition. By default, a measure group is created using a single partition that is bound to a single table in the DSV. Before you can add more partitions, you must first modify the original partition to contain just a portion of the fact data. You can then proceed to create additional partitions for storing the remainder of the data.

Construct your filters such that data is not duplicated among the partitions. A partition's filter specifies which data in the fact table is used in the partition. It is important that the filters for all partitions in a cube extract mutually exclusive datasets from the fact table. The same fact data might be double-counted if it appears in multiple partitions.

1. In Visual Studio with Analysis Services projects, in Solution Explorer, double-click the cube to open it in Cube Designer, and then click the **Partitions** tab.
2. Expand the measure group for which are adding partitions. By default, each measure group has one partition, bound to a fact table in the DSV.
3. In the Source column, click the browse (.) button to open the Partition Source dialog box.

| Partition Name | Source | Estimated Rows | Storage Mode | Aggregation Design |
|-----------------------|-------------------|----------------|--------------|--------------------|
| 1 Fact Internet Sales | FactInternetSales | 0 | MOLAP | |

[New Partition...](#) [Storage Settings...](#)

4. In Binding Type, select **Query Binding**. The SQL query that selects the data appears automatically.
5. In the WHERE clause at the bottom, add a filter that segments data for this partition.

Examples of WHERE clause syntax include `WHERE OrderDateKey >= '20060101'` or
`WHERE OrderDateKey BETWEEN '20051001' AND '20051201'`. For other examples, see [WHERE \(Transact-SQL\)](#).

Notice that the following filters are mutually exclusive within each set:

| | |
|--------|--|
| Set 1: | "SaleYear" = 2012 |
| | "SaleYear" = 2013 |
| Set 2: | "Continent" = 'NorthAmerica' |
| | "Continent" = 'Europe' |
| | "Continent" = 'SouthAmerica' |
| Set 3: | "Country" = 'USA' |
| | "Country" = 'Mexico' |
| | ("Country" <> 'USA' AND "Country" <> 'Mexico') |

6. Click **Check** to check for syntax errors, and then click **OK**.
7. Repeat the previous steps to create the remaining partitions, modifying the WHERE clause each time to select the next data slice.
8. Deploy the solution or process the partition to load the data. Be sure to process all partitions.
9. Browse the cube to verify the correct data is returned.

After you have a measure group that uses multiple measure groups, you can create additional partitions in SQL Server Management Studio. Under a measure group, right-click the Partitions folder and select **New Partitions** to start the wizard.

NOTE

Instead of filtering data in a partition, you can use the same query to create a name query in the DSV, and then base the partition on the named query.

Option 2: Use Tables, Views, or Named Queries

If the DSV already organizes facts into individual tables (for example, by year or quarter), you can create partitions based on an individual table, where each partition has its own data source table. This is essentially how measure groups are partitioned by default but in the case of multiple partitions, you break the original partition into multiple partitions, and map each new partition to the data source table providing the data.

Views and named queries are functional equivalent to tables, in that all three objects are defined in the DSV and bound to a partition using the Table Binding option in the Partition Source dialog box. You can create a view or named query to generate the data segment needed for each partition. For more information, see [Define Named Queries in a Data Source View \(Analysis Services\)](#).

IMPORTANT

When you create mutually exclusive named queries for partitions in a DSV, ensure that the combined data for the partitions includes all data from a measure group that you want to include in the cube. Make sure that you do not leave a default partition based on the entire table for the measure group, or else the query based partitions will overlap the query based on the complete table.

1. Create one or more named queries to use as the partition source. For more information, see [Define Named Queries in a Data Source View \(Analysis Services\)](#).

The named query must be based on the fact table associated with the measure group. For example, if you are partitioning the FactInternetSales measure group, the named queries in the DSV must specify the FactInternetSales table in the FROM statement.

2. In Visual Studio with Analysis Services projects, in Solution Explorer, double-click the cube to open it in Cube Designer, and then click the **Partitions** tab.
3. Expand the measure group for which are adding partitions.
4. Click **New Partition** to start the Partition Wizard. If you created the named queries using the fact table bound to the measure group, you should see each of the named queries you created in the previous step.
5. In Specify Source Information, choose one of the named queries you created in a previous step. If you do not see any named queries, go back to the DSV and check the FROM statement.
6. Click **Next** to accept the default values for each subsequent page.
7. On the last page, Completing the Wizard, give the partition a descriptive name.
8. Click **Finish**.
9. Repeat the previous steps to create the remaining partitions, choosing a different named query each time to select the next data slice.
10. Deploy the solution or process the partition to load the data. Be sure to process all partitions.
11. Browse the cube to verify the correct data is returned.

Next Step

When you create mutually exclusive queries for partitions, ensure that the combined partition data includes all data you want to include in the cube.

As a final step, you normally want to remove the default partition that was based on the table itself (if it still exists), or else the query based partitions will overlap the query based on the complete table.

[Remote Partitions](#)

[Merge Partitions in Analysis Services \(SSAS - Multidimensional\)](#)

Create and Manage a Remote Partition (Analysis Services)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When partitioning a measure group, you can configure a secondary database on a remote Analysis Services instance as partition storage.

Remote partitions for a cube (called the master database) are stored in a dedicated Analysis Services database on the remote instance of Analysis Services (called the secondary database).

A dedicated secondary database can store remote partitions for one and only one master database, but the master database can use multiple secondary databases, as long as all the secondary databases are on the same remote instance of Analysis Services. Dimensions in a database dedicated to remote partitions are created as linked dimensions.

Prerequisites

Before you create a remote partition, the following conditions must be met:

- You must have a second Analysis Services instance and dedicated database to store the partitions. The secondary database is single-purpose; it provides storage of remote partitions for a master database.
- Both server instances must be the same version. Both databases should be the same functional level.
- Both instances must be configured for TCP connections. Analysis Services does not support creation of remote partitions by using the HTTP protocol.
- Firewall settings on both computers must be set to accept outside connections. For information about setting the firewall, see [Configure the Windows Firewall to Allow Analysis Services Access](#).
- The service account for the instance running the master database must have administrative access to the remote instance of Analysis Services. If the service account changes, you must update permissions on both the server and database.
- You must be an Analysis Services administrator on both computers.
- You must ensure your disaster recovery plan accommodates backup and restore of the remote partitions. Using remote partitions can complicate backup and restore operations. Be sure to test your plan thoroughly to be sure you can restore the necessary data.

Configure remote partitions

Two separate computers that are running an instance of SQL Server Analysis Services are each required to create a remote partition arrangement that designates one computer as the master server and the other computer as the subordinate server.

The following procedure assumes that you have two server instances, with a cube database deployed on the master server. For the purposes of this procedure, the cube database is referred to as db-master. The storage database containing remote partitions is referred to as db-storage.

You will use both SQL Server Management Studio and Visual Studio with Analysis Services projects to complete

this procedure.

NOTE

Remote partitions can be merged only with other remote partitions. If you are using a combination of local and remote partitions, an alternative approach is to create new partitions that include the combined data, deleting the partitions you no longer use.

Specify valid server names for cube deployment (in SSDT)

1. On the master server: In Solution Explorer, right-click the solution name and select **Properties**. In the **Properties** dialog box, click **Configuration Properties**, then click **Deployment**, and then click **Server** and set the master server's name.
2. On the subordinate server: In Solution Explorer, right-click the solution name and select **Properties**. In the **Properties** dialog box, click **Configuration Properties**, then click **Deployment**, and then click **Server** and set the subordinate server's name.

Create and deploy a secondary database (in SSDT)

1. On the subordinate server: Create a new Analysis Services project for the storage database.
2. On the subordinate server: In Solution Explorer, create a new data source pointing to the cube database, db-master. Use the provider **Native OLE DB\Microsoft OLE DB Provider for Analysis Services 11.0**.
3. On the subordinate server: Deploy the solution.

Enable features (in SSMS)

1. On the subordinate server: In SQL Server Management Studio, right-click your connected Analysis Services instance in Object Explorer and select **Properties**. Set both **Feature\LinkToOtherInstanceEnabled** and **Feature\LinkFromOtherInstanceEnabled** to **True**.
2. On the subordinate server: Restart the server by right-clicking the server name in Object Explorer and selecting **Restart**.
3. On the master server: In SQL Server Management Studio, right-click your connected Analysis Services instance in Object Explorer and select **Properties**. Set both **Feature\LinkToOtherInstanceEnabled** and **Feature\LinkFromOtherInstanceEnabled** to **True**.
4. On the master server: To restart the server, right-click the server name in Object Explorer and select **Restart**.

Set the MasterDataSourceID database property on the remote server (in SSMS)

1. On the subordinate server: Right-click the storage database, db-storage, point to **Script Database as | ALTER To | New Query Editor Window**.
2. Add **MasterDataSourceID** to the XMLA, and then specify the cube database, db-master, ID as the value. The XMLA should look similar to the following.

```

<Alter ObjectExpansion="ExpandFull" xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
<Object>
  <DatabaseID>DB-Storage</DatabaseID>
</Object>
<ObjectDefinition>
  <Database xmlns:xsd="http://www.w3.org/2001/XMLSchema" 400>
    <ID>DB-Storage</ID>
    <Name>DB-StorageB</Name>
    <ddl1200:CompatibilityLevel>1100</ddl1200:CompatibilityLevel>
    <Language>1033</Language>
    <Collation>Latin1_General_CI_AS</Collation>
    <DataSourceImpersonationInfo>
      <ImpersonationMode>ImpersonateAccount</ImpersonationMode>
        <Account>*****</Account>
      </DataSourceImpersonationInfo>
      <MasterDataSourceID>DB-Master</MasterDataSourceID>
    </Database>
  </ObjectDefinition>
</Alter>

```

3. Press F5 to execute the script.

Set up the remote partition (in SSDT)

1. On the master server: Open the cube in Cube Designer and click **Partitions** tab. Expand the measure group. Click **New Partition** if the measure group is already configured for multiple partitions, or click the browse (...) button in the Source column to edit the existing partition.
2. In the Partition Wizard, in **Specify Source Information**, select the original Data Source View and fact table.
3. If using a query binding, provide a WHERE clause that segments the data for the new partition you are creating.
4. In **Processing and Storage Locations**, under **Processing Location**, choose **Remote Analysis Services data source** and click **New** to create a new data source that points to your subordinate database, db-storage.

NOTE

If you get an error indicating the data source does not exist in the collection, you must open the project of the storage database, db-storage, and create a data source that points to the master database, db-master.

5. On the master server: Right-click the cube name in Solution Explorer, select **Process** and fully process the cube.

Administering remote partitions

Analysis Services supports both parallel and sequential processing of remote partitions. The master database, where the partitions were defined, coordinates the transactions among all the instances that participate in processing the partitions of a cube. Processing reports are then sent to all instances that processed a partition.

A cube that contains remote partitions can be administered together with its partitions on a single instance of Analysis Services. However, the metadata for the remote partition can be viewed and updated only on the instance of Analysis Services where the partition and its parent cube were defined. The remote partition cannot be viewed or updated on the remote instance of Analysis Services.

NOTE

Although databases dedicated to storage of remote partitions are not exposed to schema rowsets, applications that use Analysis Management Objects (AMO) can still discover a dedicated database by using the XML for Analysis Discover command. Any CREATE or DELETE command that is sent directly to a dedicated database by using a TCP or HTTP client will succeed, but the server will return a warning indicating that the action may damage this closely managed database.

[Partitions \(Analysis Services - Multidimensional Data\)](#)

Change a partition source to use a different fact table

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you create a partition for a cube, you can choose to use a different fact table. Different tables may be from a single data source view, from different data source views, or from different data sources. A data source view may also contain different tables from more than one data source.

All fact tables and dimensions for a cube's partitions must have the same structure as the fact table and dimensions of the cube. For example, different fact tables can have the same structure but contain data for different years or different product lines.

You specify a fact table on the **Specify Source Information** page of the Partition Wizard. On this page, in the Partition Source group next to **Look in**, specify a data source or data source view in which to look. Next, click **Find Tables**, and then, under **Available Tables**, select the table you want to use.

When you use different fact tables, ensure that no data is duplicated among the partitions. For example, if one fact table contains transactions for 2012 only, and another fact table contains transactions for 2013 only, these tables contain independent data. Similarly, fact tables for distinct product lines or distinct geographical areas are independent.

It is possible, but not recommended, to use different fact tables that contain duplicated data. In this case, you must use filters in the partitions to ensure that data used by one partition is not used by any other partition. For more information, see [Create and Manage a Local Partition \(Analysis Services\)](#).

[Create and Manage a Local Partition \(Analysis Services\)](#)

Designing Aggregations (Analysis Services - Multidimensional)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Aggregations are precalculated summaries of cube data that help enable Analysis Services to provide rapid query responses.

To set storage options and design aggregations for a partition, use the Aggregation Design Wizard. The wizard operates on a single partition of a measure group at a time so that you can select different options and designs for each partition. The wizard takes you through steps to configure storage and design aggregation for a partition. For more information about configuring storage, see.

Select a method for controlling the number of aggregations the wizard will design, and then let the wizard design the aggregations.

The goal is to design the optimal number of aggregations. This number should not only provide satisfactory response time, but also prevent excessive partition size. A greater number of aggregations produces faster response times but it also requires more storage space and may take longer to compute. Moreover, as the wizard designs more and more aggregations, earlier aggregations produce considerably larger performance gains than later aggregations. Reduction in less useful aggregations increases performance as well. You can control the number of aggregations the wizard designs by one of the following methods available in the wizard:

- Specify a storage space limit for the aggregations.
- Specify a performance gain limit.
- Stop the wizard manually when the displayed performance versus size curve starts to level off at an acceptable performance gain.
- Choose not to design aggregations.

To design storage, the wizard must be able to connect to Analysis Services on the target server. The wizard will display an error message if Analysis Services is not running on the target server or if the storage design process is otherwise unable to connect to the target server.

The final step of the wizard allows you to process or defer processing. Processing creates the aggregations you design with the wizard, while deferring processing saves the designed aggregations for future processing, thus allowing design activities to continue without processing. Depending on the size of the partition, processing may take considerable time. If you choose, you can interrupt processing a partition.

Edit or Delete Partitions (Analysis Services - Multidimensional)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Cube partitions are modified using the **Partitions** tab in Cube Designer in Visual Studio with Analysis Services projects. The **Partitions** tab lists the partitions for all of the measure groups in a cube. It also lists the writeback partitions that have writeback enabled.

To edit the partitions for any measure group, expand the measure group on the **Partitions** tab. Partitions for a measure group are listed by ordinal number in a table format with the columns listed in the following table.

Settings for a linked measure group must be edited in the source cube.

Deleting partitions occurs automatically when you merge a source partition into a destination partition. The partition specified as the Source is deleted after the merge is completed. You can also delete partitions manually in SQL Server Management Studio or in the Partitions tab in Visual Studio with Analysis Services projects. Right-click and choose **Delete**. Remember that deleting a partition also deletes data and aggregations. As a precaution, make sure you have a recent back up of the database in case you need to reverse this step later.

NOTE

Alternatively, you can use XMLA scripts that automate tasks for building, merging, and deleting partitions. XMLA script can be created and executed in SQL Server Management Studio, or in custom SSIS packages that runs as a scheduled task. For more information, see [Automate Analysis Services Administrative Tasks with SSIS](#).

Partition source

Specifies the source table or named query for the partition. To change the source table, click the cell and then click the browse (...) button.

| | Partition Name | Source | Estimated Rows | Storage Mode | Aggregation Design |
|---|---------------------|-------------------|----------------|--------------|--------------------|
| 1 | Fact Internet Sales | FactInternetSales | 0 | MOLAP | |

[New Partition...](#) [Storage Settings...](#)

If the partition is based on a query, click the browse (...) button to edit the query. This edits the **Source** property for the partition. For more information, see [Change a partition source to use a different fact table](#).

You can specify a table in the data source view that has the same structure as the original source table (in the external data source from which the data is retrieved). The source can be in any of the data sources or data source views of the cube database.

Storage settings

In Cube Designer, on the Partitions tab, you can click **Storage Settings** to pick one of the standard settings for MOLAP, ROLAP, or HOLAP storage, or to configure custom settings for the storage mode and proactive caching. The default is MOLAP because it delivers the fastest query performance. For more information about each setting,

see [Set Partition Storage \(Analysis Services - Multidimensional\)](#).

Storage can be configured separately for each partition of each measure group in a cube. You can also configure the default storage settings for a cube or measure group. Storage is configured on the **Partitions** tab in the Cube Wizard.

Merge Partitions in Analysis Services (SSAS - Multidimensional)

7/16/2019 • 8 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

You can merge partitions in an existing Analysis Services database to consolidate fact data from multiple partitions of the same measure group.

[Common scenarios](#)

[Requirements](#)

[Update the Partition Source after merging partitions](#)

[Special considerations for partitions segmented by fact table or named query](#)

[How to merge partitions using SSMS](#)

[How to merge partitions using XMLA](#)

Common scenarios

The single most common configuration for partition use involves the separation of data across the dimension of time. The granularity of time associated with each partition varies depending on the business requirements specific to the project. For example, segmentation might be by years, with the most recent year divided by months, plus a separate partition for the active month. The active month partition regularly takes on new data.

When the active month is completed, that partition is merged back into the months in the year-to-date partition and the process continues. At the end of the year, a whole new year partition has been formed.

As this scenario demonstrates, merging partitions can become a routine task performed on a regular basis, providing a progressive approach for consolidating and organizing historical data.

Requirements

Partitions can be merged only if they meet all of the following criteria:

- They have the same measure group.
- They have the same structure.
- They must be in a processed state.
- They have the same storage modes.
- They contain identical aggregation designs.
- They share the same string store compatibility level (applies to partitioned distinct count measure groups only).

If the target partition is empty (that is, it has an aggregation design but no aggregations), merge will drop the aggregations for the source partitions. You must run Process Index, Process Full, or Process Default on the partition to build the aggregations.

Remote partitions can be merged only with other remote partitions that are defined with the same remote instance of Analysis Services.

NOTE

If you are using a combination of local and remote partitions, an alternative approach is to create new partitions that include the combined data, deleting the partitions you no longer use.

To create a partition that is a candidate for future merging, when you create the partition in the Partition Wizard, you can choose to copy the aggregation design from another of the cube's partitions. This ensures that these partitions have the same aggregation design. When they are merged, the aggregations of the source partition are combined with the aggregations in the target partition.

Update the Partition Source after merging partitions

Partitions are segmented by query, such as the WHERE clause of a SQL query used to process the data, or by a table or named query that provides data to the partition. The **Source** property on the partition indicates whether the partition is bound to a query or a table.

When you merge partitions, the contents of the partitions are consolidated, but the **Source** property is not updated to reflect the additional scope of the partition. This means if you subsequently reprocess a partition that retains its original **Source**, you will get incorrect data from that partition. The partition will erroneously aggregate data at the parent level. The following example illustrates this behavior.

The Problem

Suppose you have a cube containing information about three soft drink products. It has three partitions that use the same fact table. These partitions are segmented by product. Partition 1 contains data about [ColaFull], Partition 2 contains data about [ColaDecaf], and Partition 3 contains data about [ColaDiet]. If Partition 3 is merged into Partition 2, the data in the resulting partition (Partition 2) is correct and the cube data is accurate. However, when Partition 2 is processed, its content may be determined by the parent of the members at the product level. This parent, [SoftDrinks], also includes [ColaFull], the product in Partition 1. Processing Partition 2 loads the partition with data for all soft drinks, including [ColaFull]. The cube then contains duplicate data for [ColaFull] and returns incorrect data to end users.

The Solution

The solution is to update the **Source** property, adjusting either the WHERE clause or named query, or manually merging data from the underlying fact tables, to ensure that subsequent processing is accurate given the expanded scope of the partition.

In this example, after merging Partition 3 into Partition 2, you can provide a filter such as ("Product" = 'ColaDecaf' OR "Product" = 'ColaDiet') in the resulting Partition 2 to specify that only data about [ColaDecaf] and [ColaDiet] be extracted from the fact table, and the data pertaining to [ColaFull] be excluded. Alternatively, you can specify filters for Partition 2 and Partition 3 when they are created, and these filters will be combined during the merger process. In either case, after the partition is processed the cube does not contain duplicate data.

The Conclusion

After you merge partitions, always check the **Source** to verify the filter is correct for the merged data. If you started with a partition that included historical data for Q1, Q2, and Q3, and you now merge Q4, you must adjust the filter to include Q4. Otherwise, subsequent processing of the partition will yield erroneous results. It will not be correct for Q4.

Special considerations for partitions segmented by fact table or named

query

In addition to queries, partitions can also be segmented by table or named query. If the source partition and target partition use the same fact table in a data source or data source view, the **Source** property is valid after merging partitions. It specifies the fact table data that is appropriate to the resulting partition. Because the facts that are required for the resulting partition are present in the fact table, no modification to the **Source** property is necessary.

Partitions using data from multiple fact tables or named queries require additional work. You must manually merge the facts from the fact table of the source partition into the fact table of the target partition.

Alternatively, you can change the source for the merged partition to a named query that returns the contents of two separate fact tables. If this manual step is not performed, the fact table does not contain complete information.

For the same reason, partitions obtaining segmented data from named queries also require updating. The combined partition must now have a named query that returns the combined result set that was previously obtained from the separate named queries.

Partition storage considerations: MOLAP

When MOLAP partitions are merged, the facts stored in the multidimensional structures of the partitions are also merged. This results in an internally complete and consistent partition. However, the facts stored in MOLAP partitions are copies of facts in the fact table. When the partition is subsequently processed, the facts in the multidimensional structure are deleted (only for full and refresh) and data is copied from the fact table as specified by the data source and filter for the partition. If the source partition uses a different fact table from the target partition, the fact table of the source partition must be manually merged with the fact table of the target partition to ensure that a complete set of data is available when the resulting partition is processed. This applies as well if the two partitions were based on different named queries.

IMPORTANT

A merged MOLAP partition with an incomplete fact table contains an internally merged copy of fact table data and operates correctly until it is processed.

Partition storage considerations: HOLAP and ROLAP Partitions

When HOLAP or ROLAP partitions that have different fact tables are merged, the fact tables are not automatically merged. Unless the fact tables are manually merged, only the fact table associated with the target partition is available to the resulting partition. Facts associated with the source partition are not available for drilldown in the resulting partition, and when the partition is processed, aggregations do not summarize data from the unavailable table.

IMPORTANT

A merged HOLAP or ROLAP partition with an incomplete fact table contains accurate aggregations, but incomplete facts. Queries that refer to missing facts return incorrect data. When the partition is processed, aggregations are computed only from available facts.

The absence of unavailable facts might not be noticed unless a user attempts to drill down to a fact in the unavailable table or executes a query that requires a fact from the unavailable table. Because aggregations are combined during the merge process, queries whose results are based only on aggregations return accurate data, whereas other queries may return inaccurate data. Even after the resulting partition is processed, the missing data

from the unavailable fact table may not be noticed, especially if it represents only a small portion of the combined data.

Fact tables can be merged before or after merging the partitions. However, the aggregations will not accurately represent the underlying facts until both operations have been completed. It is recommended that you merge HOLAP or ROLAP partitions that access different fact tables when users are not connected to the cube that contains these partitions.

How to merge partitions using SSMS

IMPORTANT

Before merging partitions, first copy the data filter information (often, the WHERE clause for filters based on SQL queries). Later, after the merge is completed, you should update the Partition Source property of the partition containing the accumulated fact data.

1. In Object Explorer, expand the **Measure Groups** node of the cube containing the partitions that you want to merge, expand **Partitions**, right-click the partition that is the target or destination of the merge operation. For example, if you are moving quarterly fact data to a partition that stores annual fact data, select the partition that contains the annual fact data.
2. Click **Merge Partitions** to open the **Merge Partition <partition name>** dialog box.
3. Under **Source Partitions**, select the check box next to each source partition that you want to merge with the target partition, and click **OK**.

NOTE

Source partitions are immediately deleted after the source is merged into the target partition. Refresh the Partitions folder to update its contents after the merge is completed.

4. Right-click the partition containing the accumulated data and select **Properties**.
5. Open the **Source** property and modify the WHERE clause so that it includes the partition data you just merged. Recall that the **Source** property is not updated automatically. If you reprocess without first updating the **Source**, you might not get all of the expected data.

How to merge partitions using XMLA

Set Partition Storage (Analysis Services - Multidimensional)

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Microsoft SQL Server Analysis Services provides several standard storage configurations for storage modes and caching options. These provide commonly used configurations for update notification, latency, and rebuilding data.

You can specify partition storage in the Partitions tab of the cube in Visual Studio with Analysis Services projects, or on the partition property page in SQL Server Management Studio.

Guidelines for choosing a storage mode

For a large measure group, it's common practice to configure storage differently for different partitions. Consider the following guidelines:

- Use real-time ROLAP for current data that is being continuously updated.
- Use proactive caching with low latency or medium latency for partitions based on data sources that are being updated less frequently.
- Use automatic MOLAP for data sources of which users require high performance but can afford some latency of the data.
- Use scheduled MOLAP for data sources for which users need to be able to continuously access the data but see changes only periodically.
- Use MOLAP storage without proactive caching for partitions that are changing infrequently or not at all; for partitions for which users do not need to browse the most recent data; and if the data does not have to be continuously available to users during any necessary updates and processing.

These are general guidelines, and careful analysis and testing may be necessary to develop the best possible storage scheme for your data. You may also manually configure storage settings for a partition if none of the standard configurations meet your needs.

Storage Settings Descriptions

| STANDARD STORAGE SETTING | DESCRIPTION |
|--------------------------|--|
| Real Time ROLAP | <p>OLAP is in real time. Detail data and aggregations are stored in relational format. The server listens for notifications when data changes and all queries reflect the current state of the data (zero latency).</p> <p>This setting would typically be used for a data source with very frequent and continuous updates when the very latest data is always required by users. Depending on the types of queries generated by client applications, this method is liable to give the slowest response times.</p> |

| Standard Storage Setting | Description |
|--------------------------|--|
| Real Time HOLAP | <p>OLAP is in real time. Detail data is stored in a relational format while aggregations are stored in a multidimensional format. The server listens for notifications when data changes and refreshes the multidimensional OLAP (MOLAP) aggregations as needed. No MOLAP cache is created. Whenever the data source is updated, the server switches to real-time relational OLAP (ROLAP) until the aggregations are refreshed. All queries reflect the current state of the data (zero latency).</p> <p>This setting would typically be used for a data source with frequent and continuous updates (but not so frequent as to require real-time ROLAP) and users always require the latest data. This method normally provides better overall performance than ROLAP storage. Users can get MOLAP performance from this setting if the data source stays silent long enough.</p> |
| Low Latency MOLAP | <p>Detail data and aggregations are stored in multidimensional format. The server listens for notifications of changes to the data and switches to real-time ROLAP while MOLAP objects are reprocessed in a cache. A silence interval of at least 10 seconds is required before updating the cache. There is an override interval of 10 minutes if the silence interval is not attained. Processing occurs automatically as data changes with a target latency of 30 minutes after the first change.</p> <p>This setting would typically be used for a data source with frequent updates when query performance is somewhat more important than always providing the most current data. This setting automatically processes MOLAP objects whenever required after the latency interval. Performance is slower while the MOLAP objects are being reprocessed.</p> |
| Medium Latency MOLAP | <p>Detail data and aggregations are stored in multidimensional format. The server listens for notifications of changes to the data and switches to real-time ROLAP while MOLAP objects are reprocessed in cache. A silence interval of at least 10 seconds is required before updating the cache. There is an override interval of 10 minutes if the silence interval is not attained. Processing occurs automatically as data changes with a target latency of four hours.</p> <p>This setting is typically used for a data source with frequent (or less frequent) updates when query performance is more important than always providing the most current data. This setting automatically processes MOLAP objects whenever required after the latency interval. Performance is slower while the MOLAP objects are being reprocessed.</p> |

| STANDARD STORAGE SETTING | DESCRIPTION |
|--------------------------|--|
| Automatic MOLAP | <p>Detail data and aggregations are stored in multidimensional format. The server listens for notifications but retains the current MOLAP cache while it builds a new one. The server never switches to real-time OLAP, and queries may be stale while the new cache is built.</p> <p>A silence interval of at least 10 seconds is required before creating the new MOLAP cache. There is an override interval of 10 minutes if the silence interval is not attained. Processing occurs automatically as data changes with a target latency of two hours.</p> <p>This setting is typically used for a data source when query performance is of key importance. This setting automatically processes MOLAP objects whenever required after the latency interval. Queries do not return the most recent data while the new cache is being built and processed.</p> |
| Scheduled MOLAP | <p>Detail data and aggregations are stored in a multidimensional format. The server does not receive notifications when data changes. Processing occurs automatically every 24 hours.</p> <p>This setting is typically used for a data source when only daily updates are required. Queries are always against data in the MOLAP cache, which is not discarded until a new cache is built and its objects are processed.</p> |
| MOLAP | <p>Proactive caching is not enabled. Detail data and aggregations are stored in multidimensional format. The server does not receive notifications when data changes. Processing must either be scheduled or performed manually.</p> <p>This setting is typically used for a data source in which periodic updates are unnecessary for the client applications but for which high performance is critical.</p> <p>MOLAP storage without proactive caching provides the best possible performance if your applications do not require the most recent data. It does require downtime to process updated objects, although downtime can be minimized by updating and processing cubes on a staging server and using database synchronization to copy the updated and processed MOLAP objects to the production server.</p> |

Custom Storage Options

Instead of using one of the standard storage settings, you can manually configure storage and proactive caching. Before you create custom storage settings, you may want to first click the **Standard settings** option and move the slider to the standard setting that most closely matches the configuration you want to use. Then, to create a custom configuration, click the **Custom settings** option and click **Options**.

- You can specify whether changes in a data source trigger updates to the cache. To allow for a tolerable level of churn, you can specify a minimum silence interval after updates to the data source. You can also specify a silence interval override that updates the cache after a specified period if the interval between changes to the data source never reaches the minimum.
- You can specify whether to drop the outdated cache when updates occur. If you select this option, then when the specified latency is exceeded, the server switches to real-time relational OLAP (ROLAP) while it

updates the cache. If you do not select this option, the server continues to query the stale multidimensional OLAP (MOLAP) cache while it builds the new one.

You can specify the latency interval that must occur between changes and dropping an outdated cache. This is the amount of time users may continue browsing data in an outdated cache before it is dropped. If changes occur and the cache is still being updated or processed at the end of this interval, queries will be redirected to ROLAP.

- You can schedule forced updates of the cache if you want to periodically update the cached MOLAP objects regardless of changes to the data source. Real-time OLAP benefits vary with the size of your database and the latency period assigned by frequency of source data changes. You want users sending queries to a cache as often as possible, not to ROLAP.

If you select the **Apply settings to dimensions** check box, the same storage settings are applied to the dimensions related to the measure group. The dimension values are initially the same as the partition values.

[Partitions in Multidimensional Models](#)

Set the Partition Slice Property (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A data slice is an important optimization feature that helps direct queries to the data of the appropriate partitions. Explicitly setting the Slice property can improve query performance by overriding default slices generated for MOLAP and HOLAP partitions. Additionally, the Slice property provides an extra validation check when processing the partition.

You can specify a data slice after you create a partition, but before processing it, using the Slice property. On the Partitions tab, expand a measure group, right-click a partition, and select **Properties**.

For an explanation of data slice benefits, see [Set the Slice on your SSAS Cube Partition](#).

Defining a Slice

Valid values for a slice property are an MDX member, set, or tuple. The following examples illustrate valid slice syntax:

| SLICE | MEMBER, SET OR TUPLE |
|---|--|
| [Date].[Calendar].[Calendar Year].&[2010] | Specify this slice on a partition containing facts from year 2010 (assuming the model includes a Date dimension with Calendar Year hierarchy, where 2010 is a member). Although the partition source WHERE clause or table might already filter by 2010, specifying the Slice provides an additional check during processing, as well as more targeted scans during query execution. |
| { [Sales Territory].[Sales Territory Country].&[Australia], [Sales Territory].[Sales Territory Country].&[Canada] } | Specify this slice on a partition containing facts that include sales territory information. A slice can be an MDX set consisting of two or more members. |
| [Measures].[Sales Amount Quota] > '5000' | This slice shows an MDX expression. |

A data slice of a partition should reflect, as closely as possible, the data in the partition. For example, if a partition is limited to 2012 data, the partition's data slice should specify the 2012 member of the Time dimension. It is not always possible to specify a data slice that reflects the exact contents of a partition. For example, if a partition contains data for only January and February, but the levels of the Time dimension are Year, Quarter, and Month, the Partition Wizard cannot select both the January and February members. In such cases, select the parent of the members that reflect the partition's contents. In this example, select Quarter 1.

NOTE

Note that dynamic MDX functions (such as [Generate \(MDX\)](#) or [Except \(MDX\)](#)) are not supported in the Slice property for partitions. You must define the slice by using explicit tuples or member references.

For example, rather than using the range operator (:) to define a range, you would need to enumerate each member by the specific years.

If you need to define a complex slice, we recommend that you define the tuples in the slice by using an XMLA Alter script. Then, you can use either the ascmd command-line tool or the [Analysis Services Execute DDL Task](#) in Integration Services to run the script and create the specified set of members immediately before you process the partition.

[Create and Manage a Local Partition \(Analysis Services\)](#)

Set Partition Writeback

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

If you write-enable a measure group, end users can change cube data while they browse it, where changes are saved in a separate table called a writeback table, not in the cube data or source data. End users who browse a write-enabled partition see the net effect of all changes in the writeback table for the partition.

You can browse or delete writeback data. You can also convert writeback data to a partition. On a write-enabled partition, you can use cube roles to grant read/write access to users and groups of users, and to limit access to specific cells or groups of cells in the partition.

For a short video introduction to writeback, see [Excel 2010 Writeback to Analysis Services](#). A more detailed exploration of this feature is available through this blog post series, [Building a Writeback Application with Analysis Services \(blog\)](#).

NOTE

Writeback is supported for SQL Server relational databases and data marts only, and only for Analysis Services multidimensional models.

How to write-enable a partition

You can write-enable a partition's measure groups by write-enabling the partition itself in Cube Designer in Visual Studio with Analysis Services projects or SQL Server Management Studio.

- In Cube Designer, in the Partitions tab, right-click a partition and choose **Writeback Settings**.
- In Management Studio, expand the database | cube | measure group, and then right-click **Writeback** and choose **Enable Writeback**.

Writeback is only supported for measures that use the SUM aggregation. In the AdventureWorks sample database, you can use the Sales Targets measure group to test writeback behaviors.

When you write-enable a partition, you specify a table name and a data source for storing the write-back table. Any subsequent changes to the measure group are recorded in this table.

Browse writeback data in a partition

You can browse the contents of a cube's writeback table in the **Browse Data** dialog box, which you can access by right-clicking a write-enabled partition on the **Partitions** tab in Cube Designer.

Delete writeback data or disable writeback

Deleting writeback data clears the writeback cache; as soon as that data is deleted, additional writeback work is performed on a clean slate. Disabling writeback for a cube partition simply turns off writeback for that partition.

Convert writeback data to a partition

You can convert the data in a partition's writeback table to a partition. This procedure causes the writeback table to become the new partition's fact table.

Caution

Incorrect use of partitions can result in inaccurate cube data. For more information, see [Create and Manage a Local Partition \(Analysis Services\)](#).

Converting the writeback data table to a partition also write-disables the partition. All unrestricted read/write policies and read/write permissions for the partition's cells are disabled, and end users will not be able to change displayed cube data. (End users with disabled unrestricted read/write policies or disabled read/write permissions will still be able to browse the cube.) Read and read-contingent permissions are not affected.

To convert writeback data to a partition, use the **Convert to Partition** dialog box, which is accessed by right-clicking the writeback table for a write-enabled partition in SQL Server Management Studio. You specify a name for the partition and whether to design the aggregation for the partition later or at the same time that you create it. To create the aggregation at the same time you choose the partition, you must choose to copy the aggregation design from an existing partition. This is normally, but not necessarily, the current writeback partition. You can also choose to process the partition at the same time that you create it.

Calculations in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Use the **Calculations** tab of Cube Designer to create calculated members, named sets, and other Multidimensional Expressions (MDX) calculations.

The **Calculations** tab has the following three panes:

- The **Script Organizer** pane lists the calculations in a cube. Use this pane to create, organize, and select calculations for editing.
- The **Calculation Tools** pane provides metadata, functions, and templates with which to create calculations.
- The Calculation Expressions pane supports a form view and a script view.

Creating a New Calculation

To create a new calculation, on the **Calculations** tab of Cube Designer, on the **Cube** menu, click either **New Calculated Member**, **New Named Set**, or **New Script Command**, depending on the type of calculation you want to create. You can also click any of the corresponding buttons on the toolbar, or right-click anywhere in the **Script Organizer** pane and then click one of the commands on the shortcut menu. This action adds a new calculation to the **Script Organizer** pane and displays fields for it in the calculations form in the Calculations Expressions pane. If you create a new script, this action opens the Script view in the Calculation Expressions pane. For more information about building the three types of calculations, see [Create Calculated Members](#), [Create Named Sets](#), and [Define Assignments and Other Script Commands](#).

Editing Scripts

Edit scripts in the Calculation Expressions pane of the **Calculations** tab. The Calculation Expressions pane has two views, Script view and Form view. The Form view shows the expressions and properties for a single command. When you edit an MDX script, an expression box fills the entire Form view.

The Script view provides a code editor in which to edit the scripts. While the Calculation Expressions pane is in Script view, the **Script Organizer** pane is hidden. The Script view provides color coding, parenthesis matching, auto-complete, and MDX code regions. The MDX code regions can be collapsed or expanded to facilitate editing.

You can switch between the Form view and the Script view by clicking the **Cube** menu, pointing to **Show Calculations in**, and then clicking **Script** or **Form**. You can also click either **Form view** or **Script view** on the toolbar.

Changing Solve Order

Calculations are solved in the order listed in the **Script Organizer** pane. You can reorder the calculations by right-clicking any calculation and then clicking **Move Up** or **Move Down** on the shortcut menu. You can also click a calculation and then click the **Move Up** or **Move Down** button on the toolbar.

You can override this order manually for calculated cells and calculated members. For more information about pass order and solve order, see [Understanding Pass Order and Solve Order \(MDX\)](#).

Deleting a Calculation

To delete an existing calculation, on the **Calculations** tab, in the **Script Organizer** pane, select the calculation to be deleted, and then click **Delete** on the **Edit** menu or click the **Delete** icon on the toolbar. You can also right-click the calculation in the **Script Organizer** pane and select **Delete** from the short-cut menu.

Create Calculated Members

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can create customized measures or dimension members, called calculated members, by combining cube data, arithmetic operators, numbers, and functions. For example, you can create a calculated member named Euros that converts dollars to euros by multiplying an existing dollar measure by a conversion rate. Euros can then be displayed to end users in a separate row or column.

Calculated member definitions are stored, but their values exist only in memory. In the preceding example, values in euros are displayed to end users but are not stored as cube data.

You create calculated members in cubes. To create a calculated member, in Cube Designer, on the **Calculations** tab, click the **New Calculated Member** icon on the toolbar. This command displays a form to specify the following options for the calculated member:

Name

Select the name of the calculated member. This name appears as the column or row heading for the calculated member values when end users browse the cube.

Parent hierarchy

Select the parent hierarchy to include in the calculated member. Hierarchies are descriptive categories of a dimension by which the numeric data (that is, measures) in a cube can be separated for analysis. In tabular browsers, hierarchies provide the column and row headings displayed to end users when they browse data in a cube. (In graphical browsers, they provide other types of descriptive labels, but they have the same function as in tabular browsers.) A calculated member provides a new heading (or label) in the parent dimension you select.

Alternatively, you can include the calculated member in the measures instead of in a dimension. This option also provides a new column or row heading, but it is attached to measures in the browser.

Parent member

Click **Change** to select a parent member to include the calculated member. This option is unavailable if you select a one-level hierarchy or **MEASURES** as the parent dimension.

Hierarchies are divided into levels that contain members. Each member produces a heading. While browsing data in a cube, end users can drill down from a selected heading to previously undisplayed subordinate headings. The heading for the calculated member is added at the level directly below the parent member you select.

Expression

Specify the expression that produces the values of the calculated member. This expression can be written in Multidimensional Expressions (MDX). The expression can contain any of the following:

- Data expressions that represent cube components such as dimensions, levels, measures, and so on
- Arithmetic operators
- Numbers
- Functions

You can drag or copy cube components from the **Metadata** tab of the **Calculation Tools** pane to quickly add them to an expression.

IMPORTANT

Any calculated member that is to be used in the value expression of another calculated member must be created before the calculated member that uses it.

Format String

Specifies the format of cell values that are based on the calculated member. This property accepts the same values as the **Display Format** property for measures. For more information about display formats, see [Configure Measure Properties](#).

Visible

Determines whether the calculated member is visible or hidden when cube metadata is retrieved. If the calculated member is hidden, it can still be used in MDX expressions, statements, and scripts, but it is not displayed as a selectable object in client user interfaces.

Non-empty Behavior

Stores the names of measures used to resolve NON EMPTY queries in MDX. If this property is blank, the calculated member must be evaluated repeatedly to determine whether a member is empty. If this property contains the name of one or more measures, the calculated member is treated as empty if all the specified measures are empty. This property is an optimization hint to Analysis Services to return only non-NULL records. Returning only non-NULL records improves the performance of MDX queries that utilize the NON EMPTY operator or the NonEmpty function, or that require the calculation of cell values. For best performance with cell calculations, specify only a single member when possible.

Color Expressions

Specifies MDX expressions that dynamically set the foreground and background colors of cells based on the value of the calculated member. This property is ignored if unsupported by client applications.

Font Expressions

Specifies MDX expressions that dynamically set the font, font size, and font attributes for cells based on the value of the calculated member. This property is ignored if unsupported by client applications.

You can copy or drag cube components from the **Metadata** tab of the **Calculation Tools** pane to the **Expression** box in the Calculation Expressions pane. You can copy or drag functions from the **Functions** tab in the **Calculation Tools** pane to the **Expression** box in the Calculation Expressions pane.

Addressing Calculated Members

When you create a calculated member on the **Calculations** tab of **Cube Designer**, you specify the parent hierarchy in which the calculated member is stored. The parent hierarchy determines how a calculated member can be addressed, according to the following rules:

- If a calculated member is created in the measures dimension, the calculated member is addressable in that dimension.

[Calculations in Multidimensional Models](#)

Create Named Sets

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A named set is a set of dimension members or a set expression that is created for reuse, for example in Multidimensional Expressions (MDX) queries. You can create named sets by combining cube data, arithmetic operators, numbers, and functions. For example, you can create a named set called Top Ten Factories that contains the ten members of the Factories dimension that have the highest values for the Production measure. Top Ten Factories can then be used in queries by end users. For example, an end user can place Top Ten Factories on one axis and the Measures dimension, including Production, on another axis. For more information, see [Calculations in Multidimensional Models](#), and [Building Named Sets in MDX \(MDX\)](#).

To create a named set, use the **New Named Set** command on the **Calculations** tab of Cube Designer. This command can be invoked on the **Cube** menu on the **Calculations** tab toolbar. This command displays a form to specify the following options for the named set:

Name

Select the name of the named set. This name appears to end users when they browse the cube.

Expression

Specify the expression that produces the named set. This expression can be written in MDX. The expression can contain any of the following:

- Data expressions that represent cube components such as dimensions, levels, measures, and so on.
- Arithmetic operators.
- Numbers.
- Functions.

You can copy or drag cube components from the **Metadata** tab of the **Calculation Tools** pane to the **Expression** box in the **Named Set Form Editor** pane. You can copy or drag functions from the **Functions** tab in the **Calculation Tools** pane to the **Expression** box in the **Named Set Form Editor** pane.

IMPORTANT

If you create the set expression by explicitly naming the members in the set, enclose the list of members in a pair of braces {}.

See Also

[Calculations in Multidimensional Models](#)

Define Assignments and Other Script Commands

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

On the **Calculations** tab of Cube Designer, click the **New ScriptCommand** icon on the toolbar to create an empty script. When you create a new script, it initially is displayed with a blank title in the **Script Organizer** pane of the Calculations tab. The characters you type in the Calculation Expressions pane will be visible as the name of the item in **Script Organizer**. Therefore, you may want to type a commented name on the first line to more easily identify the script in the **Script Organizer** pane. For more information, see [Introduction to MDX Scripting in Microsoft SQL Server 2005](#).

IMPORTANT

When you initially switch to the **Calculations** tab of Cube Designer, the **Script Organizer** pane contains a single script with a CALCULATE command. The CALCULATE command controls the aggregation of the cells in the cube and should be edited only if you intend to manually specify how the cube is to be aggregated.

You can use the Calculation Expressions pane to build an expression in Multidimensional Expressions (MDX) syntax. While you build the expression, you can drag or copy cube components, functions, and templates from the **Calculation Tools** pane to the Calculation Expressions pane. Doing so adds the script for the item to the Calculation Expressions pane in the location that you drop or paste it. Replace arguments and their delimiters (« and ») with the appropriate values.

IMPORTANT

When writing an expression that contains multiple statements using the Calculation Expressions pane, ensure that all lines except the last line of the MDX script end with a semi-colon (;). Calculations are concatenated into a single MDX script, and each script has a semi-colon appended to it to ensure that the MDX script compiles correctly. If you add a semi-colon to the last line of the script in the Calculation Expressions pane, the cube will build and deploy correctly but you will be unable to run queries against it.

[Calculations in Multidimensional Models](#)

Define Time Intelligence Calculations using the Business Intelligence Wizard

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The time intelligence enhancement is a cube enhancement that adds time calculations (or time views) to a selected hierarchy. This enhancement supports the following categories of calculations:

- Period to date.
- Period over period growth.
- Moving averages.
- Parallel period comparisons.

You apply time intelligence to cubes that have a time dimension. (A time dimension is a dimension whose **Type** property is set to **Time**). Additionally, the time attributes of that dimension must also have the appropriate setting (such as, Years or Months) for their **Type** property. The **Type** property of both the dimension and its attributes will be set correctly if you use the Dimension Wizard to create the time dimension.

To add time intelligence to a cube, you use the Business Intelligence Wizard, and select the **Define time intelligence** option on the **Choose Enhancement** page. This wizard then guides you through the steps of selecting a hierarchy to which you are adding time intelligence and specifying which members in the hierarchy will have time intelligence applied to them. On the last page of the wizard, you can see the changes that will be made to the Microsoft SQL Server Analysis Services database to add the selected time intelligence.

Selecting a Time Hierarchy

On the **Choose Target Hierarchy and Calculations** page, you select the time hierarchy to which the time enhancement applies. You can apply the time enhancement to only one time hierarchy every time that you run the Business Intelligence Wizard. If you want to apply the enhancement to more than one time hierarchy, you run the wizard again.

After you select a time hierarchy, in the **Available time calculations** list, you select the calculations that apply to the hierarchy. The calculations that are listed depend on the levels in the hierarchy, and on the **Type** property setting for the attribute for each level. For example, a Years hierarchy supports Year to Date and Year Over Year Growth, but a Quarters hierarchy does not.

NOTE

The Timeintelligence.xml template file defines the time calculations that are listed in **Available time calculations**. If the listed calculations do not meet your needs, you can either change the existing calculations or add new calculations to the Timeintelligence.xml file.

TIP

To view a description for a calculation, use the up and down arrows to highlight that calculation.

Apply Time Views to Members

On the **Define Scope of Calculations** page, you specify the members to which the new time views apply. You can apply the new time views to one of the following objects:

- **Members of an account dimension** On the **Define Scope of Calculations** page, the **Available measures** list includes account dimensions. Account dimensions have their **Type** properties set to **Accounts**. If you have an accounts dimension but that dimension does not appear in the **Available measures** list, you can use the Business Intelligence Wizard to apply the account intelligence to that dimension. For more information, see [Add Account Intelligence to a Dimension](#).
- **Measures** Instead of specifying an account dimension, you can specify the measures to which the time views apply. In this case, select the views to which selected time calculations apply. For example, assets and liabilities are year-to-date data; therefore, you do not apply a Year-to-Date calculation to assets or liabilities measures.

Viewing the Time Intelligence Enhancement

On the final page of the Business Intelligence Wizard, you can view the changes that will be made to the Analysis Services database. For a time intelligence enhancement, the wizard will change the selected time dimension, associated data source view, and associated cube as described in the following table.

| OBJECT | CHANGE |
|------------------|---|
| Time dimension | Adds an attribute for each calculation (or view). |
| Data source view | Adds a calculated column in the time table for each new attribute in the time dimension. |
| Cube | Adds a calculated member that defines the Multidimensional Expressions (MDX) code to perform the calculation. |

[Create Calculated Members](#)

Key Performance Indicators (KPIs) in Multidimensional Models

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In business terminology, a Key Performance Indicator (KPI) is a quantifiable measurement for gauging business success.

In Analysis Services, a KPI is a collection of calculations that are associated with a measure group in a cube that are used to evaluate business success. Typically, these calculations are a combination of Multidimensional Expressions (MDX) expressions or calculated members. KPIs also have additional metadata that provides information about how client applications should display the results of the KPI's calculations.

A KPI handles information about a goal set, the actual formula of the performance recorded in the cube, and measurement to show the trend and the status of the performance. AMO is used to define the formulas and other definitions about the values of a KPI. A query interface, such as ADOMD.NET, is used by the client application to retrieve and expose the KPI values to the end user. For more information see [Developing with ADOMD.NET](#).

A simple [Kpi](#) object is composed of: basic information, the goal, the actual value achieved, a status value, a trend value, and a folder where the KPI is viewed. Basic information includes the name and description of the KPI. The goal is an MDX expression that evaluates to a number. The actual value is an MDX expression that evaluates to a number. The status and trend value are MDX expressions that evaluate to a number. The folder is a suggested location for the KPI to be presented to the client.

In business terminology, a Key Performance Indicator (KPI) is a quantifiable measurement for gauging business success. A KPI is frequently evaluated over time. For example, the sales department of an organization may use monthly gross profit as a KPI, but the human resources department of the same organization may use quarterly employee turnover. Each is an example of a KPI. Business executives frequently consume KPIs that are grouped together in a business scorecard to obtain a quick and accurate historical summary of business success.

In Microsoft SQL Server Analysis Services, a KPI is a collection of calculations, which are associated with a measure group in a cube, that are used to evaluate business success. Typically, these calculations are a combination of Multidimensional Expressions (MDX) expressions and calculated members. KPIs also have additional metadata that provides information about how client applications should display the results of a KPI's calculation.

One key advantage of KPIs in Analysis Services is that they are server-based KPIs that are consumable by different client applications. A server-based KPI presents a single version of the truth, compared to separate versions of the truth from separate client applications. Moreover, performing the sometimes complex calculations on the server instead of on each client computer may have performance benefits.

Common KPI Terms

The following table provides definitions for common KPI terms in Analysis Services.

| TERM | DEFINITION |
|------|--|
| Goal | An MDX numeric expression or a calculation that returns the target value of the KPI. |

| TERM | DEFINITION |
|---------------------|--|
| Value | An MDX numeric expression that returns the actual value of the KPI. |
| Status | <p>An MDX expression that represents the state of the KPI at a specified point in time.</p> <p>The status MDX expression should return a normalized value between -1 and 1. Values equal to or less than -1 will be interpreted as "bad" or "low." A value of zero (0) is interpreted as "acceptable" or "medium." Values equal to or greater than 1 will be interpreted as "good" or "high."</p> <p>An unlimited number of intermediate values can optionally be returned and can be used to display any number of additional states, if supported by the client application.</p> |
| Trend | <p>An MDX expression that evaluates the value of the KPI over time. The trend can be any time-based criterion that is useful in a specific business context.</p> <p>The trend MDX expression enables a business user to determine whether the KPI is improving over time or degrading over time.</p> |
| Status indicator | A visual element that provides a quick indication of the status for a KPI. The display of the element is determined by the value of the MDX expression that evaluates status. |
| Trend indicator | A visual element that provides a quick indication of the trend for a KPI. The display of the element is determined by the value of the MDX expression that evaluates trend. |
| Display folder | The folder in which the KPI will appear when a user is browsing the cube. |
| Parent KPI | A reference to an existing KPI that uses the value of the child KPI as part of computation of the parent KPI. Sometimes, a single KPI will be a computation that consists of the values for other KPIs. This property facilitates the correct display of the child KPIs underneath the parent KPI in client applications. |
| Current time member | An MDX expression that returns the member that identifies the temporal context of the KPI. |
| Weight | An MDX numeric expression that assigns a relative importance to a KPI. If the KPI is assigned to a parent KPI, the weight is used to proportionally adjust the results of the child KPI value when calculating the value of the parent KPI. |

Parent KPIs

An organization may track different business metrics at different levels. For example, only two or three KPIs may be used to gauge business success for the whole company, but these company-wide KPIs may be based on three or four other KPIs tracked by the business units throughout the company. Also, business units in a company may use different statistics to calculate the same KPI, the results of which are rolled up to the company-wide KPI.

Analysis Services lets you define a parent-child relationship between KPIs. This parent-child relationship lets the results of the child KPI be used to calculate the results of the parent KPI. Client applications can also use this relationship to appropriately display parent and child KPIs.

Weights

Weights can also be assigned to child KPIs. Weights enable Analysis Services to proportionally adjust the results of the child KPI when calculating the value of the parent KPI.

Retrieving and Displaying KPIs

The display of KPIs depends on the implementation of the client application. For example, selecting **Browser View** on the toolbar on the **KPIs** tab of Cube Designer demonstrates one possible client implementation, with graphics used to display status and trend indicators, display folders used to group KPIs, and child KPIs displayed under parent KPIs.

You can use MDX functions to retrieve individual sections of the KPI, such as the value or goal, for use in MDX expressions, statements, and scripts.

Actions in Multidimensional Models

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

An action is an end user-initiated operation upon a selected cube or portion of a cube. The operation can start an application with the selected item as a parameter, or it can retrieve information about the selected item. For more information about actions, see [Actions \(Analysis Services - Multidimensional Data\)](#).

Use the **Actions** tab of Cube Designer to build actions for a cube. Specify the following:

Name

Select a name that identifies the action.

Action Target

Select the object to which the action is attached. Generally, in client applications, the action is displayed when end users select the target object; however, the client application determines which end-user operation displays actions. For **Target type**, select from the following objects:

- Attribute members
- Cells
- Cube
- Dimension members
- Hierarchy
- Hierarchy members
- Level
- Level members

After you select the target object type, under **Target object**, select the cube object of the designated type.

Condition (Optional)

Specify an optional Multidimensional Expressions (MDX) expression that resolves to a Boolean value. If the value is **True**, the action is performed on the specified target. If the value is **False**, the action is not performed.

Action Content

Select the type of action. The following table summarizes the available types.

| TYPE | DESCRIPTION |
|-------------|--|
| Data Set | Retrieves a dataset. |
| Proprietary | Performs an operation by using an interface other than those listed in this table. |
| Row Set | Retrieves a rowset. |
| Statement | Runs an OLE DB command. |

| TYPE | DESCRIPTION |
|------|--|
| URL | Displays a variable page in an Internet browser. |

For **Action Expression**, specify the parameters that are passed when the action is run. The syntax must evaluate to a string, and you must include an expression written in MDX. For example, your MDX expression can indicate a part of the cube that is included in the syntax. MDX expressions are evaluated before the parameters are passed. Also, MDX Builder is available to help you build MDX expressions.

Additional Properties

Select the property. The following table summarizes the available properties.

| PROPERTY | DESCRIPTION |
|-----------------------|---|
| Invocation | Specifies how the action is run. Interactive, the default, specifies that the action is run when a user accesses an object. The possible settings are:

Batch

Interactive

On Open |
| Application | Describes the application of the action. |
| Description | Describes the action. |
| Caption | Provides a caption that is displayed for the action. If the caption is MDX, specify True for Caption is MDX . |
| Caption is MDX | Specify True if the caption is MDX or False if it is not. |

NOTE

You must use Analysis Services Scripting Language (ASSL) or Analysis Management Objects (AMO) to define HTML and Command Line action types. For more information, see [Action Element \(ASSL\)](#), [Type Element \(Action\) \(ASSL\)](#), and [Programming AMO OLAP Advanced Objects](#).

Creating a Reporting Action

The report server responds to URL-based requests for reports. To create a reporting action, on the **Cube** menu, click **New Reporting Action**. The following options are specific to a reporting action.

Report Server

The properties described in the following table are specified for the report server.

| PROPERTY | DESCRIPTION |
|----------------------|---|
| Server name | The name of the computer running report server. |
| Server path | The path exposed by report server. |
| Report format | HTML5, HTML3, Excel, or PDF. |

NOTE

In SQL Server 2017, you can specify Transport Layer Security (https:) in the server name property.

Parameters (Optional)

The parameters are sent to the server as part of the URL string when the action is created. They include **Parameter Name** and **Parameter Value**, which is an MDX expression.

The report server URL is constructed as follows:

```
http://  
host  
/  
virtualdirectory  
/Path&  
parametername1  
=  
parametervalue1  
& ...
```

For example:

```
http://localhost/ReportServer/Sales/YearlySalesByCategory?rs:Command=Render&Region=West
```

Creating a Drillthrough Action

A drillthrough action is defined by a rowset action, which is returned to the client application as a drillthrough statement. The action target is a member of a measure group. To create a new drillthrough action, on the **Cube** menu, click **New Drillthrough Action**. The following options are specific to a drillthrough action:

Drillthrough Columns

Select one or more dimensions and, for each dimension, the drillthrough columns returned to the client application by the action.

See Also

[Cubes in Multidimensional Models](#)

Actions (Analysis Services - Multidimensional Data)

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Actions can be of different types and they have to be created accordingly. Actions can be:

- Drillthrough actions, which return the set of rows that represents the underlying data of the selected cells of the cube where the action occurs.
- Reporting actions, which return a report from Reporting Services that is associated with the selected section of the cube where the action occurs.
- Standard actions, which return the action element (URL, HTML, DataSet, RowSet, and other elements) that is associated with the selected section of the cube where the action occurs.

A query interface, such as ADOMD.NET, is used by the client application to retrieve and expose the actions to the end user. For more information see [Developing with ADOMD.NET](#).

A simple [Action](#) object is composed of: basic information, the target where the action is to occur, a condition to limit the action scope, and the type. Basic information includes the name of the action, the description of the action, the caption suggested for the action, and others.

The target is the actual location in the cube where the action is to occur. The target is composed of a target type and a target object. Target type represents the kind of object, in the cube, where the action is to be enabled. Target type could be level members, cells, hierarchy, hierarchy members, or others. The target object is a specific object of the target type; if the target type is hierarchy, then the target object is any one of the defined hierarchies in the cube.

The condition is a **Boolean** MDX expression that is evaluated at the action event. If the condition evaluates to **true**, then the action is executed. Otherwise, the action is not executed.

The type is the kind of action to be executed. [Action](#) is an abstract class, therefore, to use it you have to use any one of the derived classes. Two kinds of actions are predefined: drillthrough and reporting. These have corresponding derived classes: [DrillThroughAction](#) and [ReportAction](#). Other actions are covered in the [StandardAction](#) class.

In Microsoft SQL Server Analysis Services, an action is a stored MDX statement that can be presented to and employed by client applications. In other words, an action is a client command that is defined and stored on the server. An action also contains information that specifies when and how the MDX statement should be displayed and handled by the client application. The operation that is specified by the action can start an application, using the information in the action as a parameter, or can retrieve information based on criteria supplied by the action.

Actions enable business users to act upon the outcomes of their analyses. By saving and reusing actions, end users can go beyond traditional analysis, which typically ends with presentation of data, and initiate solutions to discovered problems and deficiencies, thereby extending the business intelligence application beyond the cube. Actions can transform the client application from a sophisticated data rendering tool into an integral part of the enterprise's operational system. Instead of focusing on sending data as input to operational applications, end users can "close the loop" on the decision-making process. This ability to transform analytical data into decisions is crucial to the successful business intelligence application.

For example, a business user browsing a cube notices that the current stock of a certain product is low. The client application provides to the business user a list of actions, all related to low product stock value, that are retrieved from the Analysis Services database. The business user selects the Order action for the member of the cube that

represents the product. The Order action initiates a new order by calling a stored procedure in the operational database. This stored procedure generates the appropriate information to send to the order entry system.

You can exercise flexibility when you create actions: for example, an action can launch an application, or retrieve information from a database. You can configure an action to be triggered from almost any part of a cube, including dimensions, levels, members, and cells, or create multiple actions for the same portion of a cube. You can also pass string parameters to the launched applications and specify the captions displayed to end users as the action runs.

IMPORTANT

In order for a business user to use actions, the client application employed by the business user must support actions.

Types of Actions

The following table lists the types of actions that are included in Analysis Services:

| ACTION TYPE | DESCRIPTION |
|--------------|--|
| CommandLine | Executes a command at the command prompt |
| Dataset | Returns a dataset to a client application. |
| Drillthrough | Returns a drillthrough statement as an expression, which the client executes to return a rowset |
| Html | Executes an HTML script in an Internet browser |
| Proprietary | Performs an operation by using an interface other than those listed in this table. |
| Report | Submits a parameterized URL-based request to a report server and returns a report to a client application. |
| Rowset | Returns a rowset to a client application. |
| Statement | Runs an OLE DB command. |
| URL | Displays a dynamic Web page in an Internet browser. |

Resolving and Executing Actions

When a business user accesses the object for which the command object is defined, the statement associated with the action is automatically resolved, which makes it available to the client application, but the action is not automatically executed. The action is executed only when the business user performs the client-specific operation that initiates the action. For example, a client applications might display a list of actions as a pop-up menu when the business user right-clicks on a particular member or cell.

[Actions in Multidimensional Models](#)

Add a Standard Action

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You add an action to a database by using the Actions view in Cube Designer. That view can be accessed from Visual Studio with Analysis Services projects. After you create an action, it becomes available to users after you reprocess the relevant cube. For more information, see [Processing Analysis Services Objects](#).

To create an action

1. Open the cube for which you want to create an action, and then click the **Actions** tab.
2. On the toolbar, click the **New Action** icon, and then in the expression pane, do the following:
 - In **Name**, type a name for the action.
 - From the **Target type** drop-down list, select the type of object to which you want to attach the action. The object you select in **Target Type** determines the objects that are available and the type of selection that you can make in **Target Object**. The following table lists valid **Target Object** selections for each target type.

| IF YOU SELECT THE FOLLOWING TARGET TYPE | MAKE THE FOLLOWING SELECTION IN TARGET OBJECT |
|---|---|
| Attribute Members | The only valid selection is a single attribute hierarchy. The target type of the action will be all members of the attribute wherever they appear (that is, the action will apply to user-defined hierarchies as well). |
| Cells | All cells is the only selection available. If you choose Cells as a target type, you can type an expression in Condition to restrict the cells with which the action is associated. |
| Cube | CURRENTCUBE is the only selection available. The action is associated with the current cube. |
| Dimension members | Select a single dimension. The action will be associated with all members of the dimension. |
| Hierarchy | Select a single hierarchy. The action will be associated with the hierarchy object only. Attribute hierarchies appear in the list only if their AttributeHierarchyEnabled and AttributeHierarchyVisible properties are set to True . |
| Hierarchy members | Select a single hierarchy. The action will be associated with all members of the selected hierarchy. Attribute hierarchies appear in the list only if their AttributeHierarchyEnabled and AttributeHierarchyVisible properties are set to True . |
| Level | Select a single level. The action will be associated with the level object only. |

| IF YOU SELECT THE FOLLOWING TARGET TYPE | MAKE THE FOLLOWING SELECTION IN TARGET OBJECT |
|---|--|
| Level members | Select a single level. The action will be associated with all members of the selected level. |

- In **Target object**, click the arrow at the right of the text box, and in the tree view that opens, click the object to which you want to attach the action, and then click **OK**.
- (Optional.) In **Condition**, create an MDX expression to limit the target of the action. You can either type the expression manually, or you can drag items from the **Metadata** and **Functions** tabs.
- From the **Type** drop-down list, select the type of action that you want to create. The following table lists the types of actions that are available.

| TYPE | DESCRIPTION |
|-------------|---|
| Dataset | Retrieves a dataset. |
| Proprietary | Performs an operation using an interface other than those listed in this table. |
| Rowset | Retrieves a rowset. |
| Statement | Runs an OLE DB command. |
| URL | Displays a Web page in an Internet browser. |

- In **Action expression**, create an expression that defines the action. The expression must evaluate to a string. You can either type the expression manually, or you can drag items from the **Metadata** and **Functions** tabs.

3. (Optional.) Expand **Additional Properties**, and then perform one of the following steps:

- From the **Invocation** drop-down list, specify how the action is invoked. The following table describes the available options for invoking an action.

| OPTION | DESCRIPTION |
|-------------|--|
| Interactive | The action is triggered by user interaction. |
| Batch | The action runs as a batch operation. |
| On open | The action runs when a user opens the cube. |

- In **Application**, type the name of the application that is associated with the action. For example, if you create an action that takes a user to a particular Web site, the application associated with the action should be Microsoft Internet Explorer or another Web browser.

NOTE

Proprietary actions are not returned to the server unless the client application explicitly restricts the schema rowset to return only actions that match the name specified in **Application**.

- In **Action Content**, if you are using the URL type, enclose the Internet address in quotes, For example, "http://www.adventure-works.com".

- In **Description**, type a description for the action.
- In **Caption**, type a caption or an MDX expression that evaluates to a caption. This caption is displayed to end users when the action is initiated. If you do not specify a caption, the name of the action is used instead.
- From the **Caption is MDX** drop-down list, specify whether the caption is MDX. This field indicates to the server whether to evaluate the contents of **Caption** as an MDX expression.

Test an Action

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You test an action by using the Browser view in Cube Designer. Cube Designer can be accessed from Visual Studio with Analysis Services projects. After you create the action, you must process the cube before the action can be tested. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To test an action

1. Open the cube that contains the action that you want to test, then under **View**, click **Browser**.
2. Drag the target object to either **Drop Column Fields Here** or **Drop Row Fields Here**.
3. In the view pane, right-click the object to which the action is attached (for example, a cell). The action name will appear in the context menu.
4. Click the action name to test the action.

Use a Template to Create an Action

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The **Actions** view in Cube Designer contains a number of templates that you can use to create common actions. Cube Designer can be accessed from Visual Studio with Analysis Services projects.

NOTE

After you create the action, it will become available to users after you update or reprocess the cube. For more information, see [Processing a multidimensional model \(Analysis Services\)](#).

To use a template to create an action

- Open the cube for which you want to create an action, and under **Design**, click the **Actions** tab.
- Under **Calculation Tools**, click the **Templates** tab, expand the node containing the type of action you want to create, and then double-click the template you want to use.
- Fill in the required information to complete building the action based on the template.

See Also

[Actions \(Analysis Services - Multidimensional Data\)](#)

Perspectives in Multidimensional Models

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

A perspective is a subset of a cube created for a particular application or group of users. The cube itself is the default perspective. A perspective is exposed to a client as a cube. When a user views a perspective, it appears like another cube. Any changes made to cube data through writeback in the perspective are to the original cube. For more information about the views in Analysis Services, see [Perspectives](#).

Use the **Perspectives** tab in Cube Designer to create or modify perspectives in a cube. The first column of the **Perspectives** tab is the **Cube Objects** column, which lists all the objects in the cube. This corresponds to the default perspective for the cube, which is the cube itself.

Creating or Deleting Perspectives

You can add a perspective to the **Perspectives** tab by clicking **New Perspective** on the **Cube** menu. You can also click the **New Perspective** button on the toolbar, or right-click anywhere in the pane and click **New Perspective** on the shortcut menu. You can add any number of perspectives to a cube.

To remove a perspective, first click any cell in the column for the perspective that you want to delete. Then, on the **Cube** menu, click **Delete Perspective**. You can also click the **Delete Perspective** button on the toolbar, or right-click any cell in the perspective you want to delete, and then click **Delete Perspective** on the shortcut menu.

Renaming Perspectives

The first row of each perspective shows its name. When you create a perspective, the name is initially Perspective (followed by an ordinal number, starting with 1, if there is already a perspective called Perspective). You can click the name to edit it.

Hiding Objects from a Perspective

To hide an object from a perspective, clear the check box in the row that corresponds to the object in the column for the perspective. The cube objects that can be hidden from a perspective are:

- Measure groups
- Measures
- Dimensions
- Hierarchies
- Named sets
- KPIs
- Actions
- Calculated members

To view any object, expand the category (**Measure Groups**, **Dimensions**, **KPIs**, **Calculations**, or **Actions**) for any object type under **Cube Objects**. To view hierarchies or attributes in a dimension, first expand a dimension, and then expand the **Hierarchies** or **Attributes** row. To view measures in a measure group, expand the measure

group.

[Cubes in Multidimensional Models](#)

Translations in Multidimensional Models (Analysis Services)

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can define translations in Visual Studio with Analysis Services projects by using the appropriate designer for the Analysis Services object to be translated. Defining a translation creates a **Translation** object associated with the appropriate Analysis Services object that has the specified explicit literal values, in the specified language, for the properties of the associated Analysis Services object.

Elements of a multi-lingual data model

A data model used in a multi-lingual solution needs more than translated labels (field names and descriptions). It also needs to provide data values that are articulated in various language scripts. Achieving a multi-lingual solution requires that you have individual attributes, bound to columns in an external database that return the data.

Adventure Works sample databases (multidimensional as well as the relational data warehouse) demonstrate the translation capabilities of Analysis Services. The sample model includes translated captions and descriptions. The sample relational data warehouse contains columns of translated values that provide localized attribute members in the model.

To view translated data values available to the model:

1. Open the Adventure Works multidimensional model in the designer.
2. In Solution Explorer, open Data Source Views and double-click Adventure Works DW<version>.dsv.
3. Find dimDate, dimProduct, dimProductCategory, or dimProductSubcateogry. All of these dimensions contain attributes for translated members for month, day of week, product name, category name, and so on.
4. Right-click any field and select **Explore Data**. You will see English, Spanish, and French translations of each member.

Formats for date, time, and currency are not implemented through translations. To dynamically provide culturally specific formats based on the client's locale, use the Currency Conversion Wizard and **FormatString** property. See [Currency Conversions \(Analysis Services\)](#) and [FormatString Element \(ASSL\)](#) for details.

Defining Translations

Add translations to a cube

You can add translations to the cube, measure groups, measures, cube dimension, perspectives, KPIs, actions, named sets, and calculated members.

1. In Solution Explorer, double-click the cube name to open cube designer.
2. Click the **Translations** tab. All objects that support translations are listed in this page.
3. For each object, specify the target language (resolves internally to an LCID), translated caption, and translated description. The language list is consistent throughout Analysis Services, whether you are setting

the server language in Management Studio, or adding a translation override on a single attribute.

Remember that you cannot change the collation. A cube essentially uses one collation, even if you're supporting multiple languages through translated captions (there is an exception for dimension attributes, discussed below). If the languages won't sort properly under the shared collation, you will need to make copies of the cube just to accommodate your collation requirements.

4. Build and deploy the project.
5. Connect to the database using a client application, such as Excel, modifying the connection string to use the locale identifier. See [Globalization Tips and Best Practices \(Analysis Services\)](#) for details.

Add translations to a dimension and attributes

You can add translations to database dimensions, attributes, hierarchies, and levels within a hierarchy.

Translated captions are added to the model manually using your keyboard or copy-paste, but for dimension attribute members, you can obtain translated values from an external database. Specifically, the **CaptionColumn** property of an attribute can be bound to a column in a data source view.

At the attribute level, you can override collation settings, for example you might want to adjust width-sensitivity or use a binary sort for a specific attribute. In Analysis Services, collation is exposed where data bindings are defined. Because you are binding a dimension attribute translation to a different source column in the DSV, a collation setting is available so that you can specify the collation used by the source column. See [Set or Change the Column Collation](#) for details about column collation in the relational database.

1. In Solution Explorer, double-click the dimension name to open dimension designer.
2. Click the **Translations** tab. All dimension objects that support translations are listed in this page.

For each object, specify target language (resolves to an LCID), translated caption, and translated description. The language list is consistent throughout Analysis Services, whether you are setting the server language in Management Studio, or adding a translation override on a single attribute.

3. To bind an attribute to a column providing translated values:
 - a. Still in Dimension Designer | **Translations**, add a new translation. Choose the language. A new column appears on the page to accept the translated values.
 - b. Place the cursor in an empty cell adjacent to one of the attributes. The attribute cannot be the key, but all other attributes are viable choices. You should see a small button with a dot in it. Click the button to open the **Attribute Data Translation Dialog Box**.
 - c. Enter a translation for the caption. This is used as a data label in the target language, for example as a field name in a PivotTable field list.
 - d. Choose the source column that provides the translated values of attribute members. Only pre-existing columns in the table or query bound to the dimension, are available. If the column does not exist, you need to modify the data source view, dimension, and cube to pick up the column.
 - e. Choose the collation and sort order, if applicable.
4. Build and deploy the project.
5. Connect to the database using a client application, such as Excel, modifying the connection string to use the locale identifier. See [Globalization Tips and Best Practices \(Analysis Services\)](#) for details.

Add a translation of the database name

At the database level, you can add translations for the database name and description. The translated database name might be visible on client connections that specify the LCID of the language, but that depends on the tool. For example, viewing the database in Management Studio will not show the translated name, even if you specify

the locale identifier on the connection. The API used by Management Studio to connect to Analysis Services does not read the **Language** property.

1. In Solution Explorer, right-click project name | **Edit Database** to open the database designer.
2. In Translations, specify target language (resolves to an LCID), translated caption, and translated description. The language list is consistent throughout Analysis Services, whether you are setting the server language in Management Studio, or adding a translation override on a single attribute.
3. In the Properties page of the database, set **Language** to the same LCID you specified for the translation. Optionally, set the **Collation** as well if the default no longer makes sense.
4. Build and deploy the database.

Deleting Translation Objects

You can right-click a translation object in the dimension or cube designer to permanently remove it. You cannot restore or recycle a deleted object, so be sure to review the list of affected objects before continuing.

Resolving Translations

If a client application requests information in a specified language identifier, the Analysis Services instance attempts to resolve data and metadata for Analysis Services objects to the closest possible language identifier. If the client application does not specify a default language, or specifies the neutral locale identifier (0) or process default language identifier (1024), then Analysis Services uses the default language for the instance to return data and metadata for Analysis Services objects.

If the client application specifies a language identifier other than the default language identifier, the instance iterates through all available translations for all available objects. If the specified language identifier matches the language identifier of a translation, Analysis Services returns that translation. If a match cannot be found, Analysis Services attempts to use one of the following methods to return translations with a language identifier closest to the specified language identifier:

- For the following language identifiers, Analysis Services attempts to use an alternate language identifier if a translation for the specified language identifier is not defined:

| SPECIFIED LANGUAGE IDENTIFIER | ALTERNATE LANGUAGE IDENTIFIER |
|-------------------------------------|-------------------------------|
| 3076 - Chinese (Hong Kong SAR, PRC) | 1028 - Chinese (Taiwan) |
| 5124 - Chinese (Macao SAR) | 1028 - Chinese (Taiwan) |
| 1028 - Chinese (Taiwan) | Default language |
| 4100 - Chinese (Singapore) | 2052 - Chinese (PRC) |
| 2074 - Croatian | Default language |
| 3098 - Croatian (Cyrillic) | Default language |

- For all other specified language identifiers, Analysis Services extracts the primary language of the specified language identifier and retrieves the language identifier indicated by Windows as the best match for the primary language. If a translation for the best match language identifier cannot be found, or if the specified language identifier is the best match for the primary language, then the default language is used.

Multidimensional Model Solution Deployment

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After you have completed the development of an Analysis Services project, you can deploy the database to an Analysis Services server. Analysis Services provides six possible deployment methods that can be used to move the database to a test or production server. The methods are listed here in order of advantage: AMO Automation, XMLA, Deployment Wizard, Deployment Utility, Synchronize Wizard, Backup and Restore.

This topic includes the following sections:

[Deployment Methods](#)

[Deployment considerations](#)

[Related Tasks](#)

Deployment Methods

| METHOD | DESCRIPTION | LINK |
|---|---|---|
| Analysis Management Objects (AMO) Automation | AMO provides a programmatic interface to the complete command set for Analysis Services, including commands that can be used for solution deployment. As an approach for solution deployment, AMO automation is the most flexible, but it also requires a programming effort. A key advantage to using AMO is that you can use SQL Server Agent with your AMO application to run deployment on a preset schedule. | Developing with Analysis Management Objects (AMO) |

| METHOD | DESCRIPTION | LINK |
|---------------------------|---|--|
| XMLA | <p>Use SQL Server Management Studio to generate an XMLA script of the metadata of an existing Analysis Services database, and then run that script on another server to recreate the initial database. XMLA scripts are easily formed in SQL Server Management Studio by defining the deployment process, then codifying it and saving it in an XMLA script. Once you have the XMLA script in a saved file, you can easily run the script according to a schedule, or embed the script in an application that connects directly to an instance of Analysis Services.</p> <p>You can also run XMLA Scripts on a preset basis using SQL Server Agent, but you do not have the same flexibility with XMLA Scripts as with AMO. AMO provides a larger breadth of functionality by hosting the complete spectrum of administrative commands.</p> | Deploy Model Solutions Using XMLA |
| Deployment Wizard | <p>Use the Deployment Wizard to use the XMLA output files generated by an Analysis Services project to deploy the project's metadata to a destination server. With the Deployment Wizard, you can deploy directly from the Analysis Services file, as created by the output directory by project build.</p> <p>The primary advantage of using the Analysis Services Deployment Wizard is convenience. Just as you can save an XMLA script for use later in SQL Server Management Studio, you can save Deployment Wizard scripts. The Deployment Wizard can be run both interactively and at the command prompt via the Deployment Utility.</p> | Deploy Model Solutions Using the Deployment Wizard |
| Deployment Utility | The Deployment utility lets you start the Analysis Services deployment engine from a command prompt. | Deploy Model Solutions with the Deployment Utility |

| METHOD | DESCRIPTION | LINK |
|------------------------------------|---|---|
| Synchronize Database Wizard | <p>Use the Synchronize Database Wizard to synchronize the metadata and data between any two Analysis Services databases.</p> <p>The Synchronize Wizard can be used to copy both data and metadata from a source server to a destination server. If the destination server does not have a copy of the database that you want to deploy, a new database is copied to the destination server. If the destination server already has a copy of the same database, the database on the destination server is updated to use the metadata and data of the source database.</p> | Synchronize Analysis Services Databases |
| Backup and Restore | <p>Backup offers the simplest approach to transferring Analysis Services databases. From the Backup dialog box, you can set the options configuration, and then you can run the backup from the dialog box itself. Or, you can create a script that can be saved and run as frequently as required.</p> <p>Backup and restore is not used as frequently as the other deployment methods, but is a way to quickly complete a deployment with minimal infrastructure requirements.</p> | Backup and Restore of Analysis Services Databases |

Deployment considerations

Before you deploy an Analysis Services project, consider which of these questions apply to your solution and then review the related link to learn ways of addressing the issue:

| CONSIDERATION | LINK TO MORE INFORMATION |
|--|---|
| What hardware and software resources are required for this solution? | Requirements and Considerations for Analysis Services Deployment |
| How will you deploy related objects that are outside the scope of the Analysis Services project, such as Integration Services packages, reports, or relational database schemas? | |
| How will you load and update the data in the deployed Analysis Services database? | Deployment Methods in this topic. |
| How will you update the metadata (such as calculations) in the deployed Analysis Services database? | |
| Do you want to give users access to Analysis Services data through the Internet? | Configure HTTP Access to Analysis Services on Internet Information Services (IIS) 8.0 |

| CONSIDERATION | LINK TO MORE INFORMATION |
|--|--|
| Do you want to provide continuous query access to Analysis Services data? | Requirements and Considerations for Analysis Services Deployment |
| Do you want to deploy objects in a distributed environment by using linked objects or remote partitions? | Create and Manage a Local Partition (Analysis Services) ,
Create and Manage a Remote Partition (Analysis Services) and
Linked Measure Groups . |
| How will you secure the Analysis Services data? | Authorizing access to objects and operations (Analysis Services) |

Requirements and Considerations for Analysis Services Deployment

7/16/2019 • 6 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

The performance and availability of a solution depends on many factors, including the capabilities of the underlying hardware, the topology of your server deployment, the characteristics of your solution (for example, having partitions distributed across multiple servers or using ROLAP storage that requires direct access to the relational engine), service level agreements, and the complexity of your data model.

Memory and Processor Requirements

Analysis Services needs more memory and processor resources in the following cases:

- When processing large or complex cubes. These require more memory and processor resources than small or simple cubes.
- When the number of cubes within a single database increases.
- When the number of databases within a single instance of Analysis Services increases.
- When the number of instances of Analysis Services on a single computer increases.
- When the number of users who are accessing Analysis Services resources simultaneously increases.

The amount of memory and processor resources that are available to Analysis Services varies depending on the edition of SQL Server, operating system, hardware capability, and whether you are using virtual or physical processors. For more information, follow these links:

[Hardware and Software Requirements for Installing SQL Server 2016](#)

[Compute Capacity Limits by Edition of SQL Server](#)

[Features Supported by the Editions of SQL Server 2016](#)

[Maximum Capacity Specifications \(Analysis Services\)](#)

Disk Space Requirements

Different aspects of your Analysis Services installation and the tasks related to object processing require different amounts of disk space. The following list describes these requirements.

Cubes

Cubes that have large fact tables require more disk space than cubes that have small fact tables. Similarly, although to a lesser extent, cubes that have many large dimensions require more disk space than cubes that have fewer dimension members. Generally, you can expect that an Analysis Services database will require approximately 20 percent of the amount of space required for the same data stored in the underlying relational database.

Aggregations

Aggregations require additional space proportional to aggregations added—the more aggregations there are, the more space is required. If you avoid creating unneeded aggregations, the additional disk space that is needed for aggregations typically should not exceed approximately 10 percent of the size of the data that is stored in the

underlying relational database.

Data Mining

By default, mining structures cache to disk the dataset with which they are trained. To remove this cached data from the disk, you can use the **Process Clear Structure** processing option on the mining structure object. For more information, see [Processing Requirements and Considerations \(Data Mining\)](#).

Object Processing

During processing, Analysis Services stores copies of the objects it is processing in the processing transaction on disk until the processing is finished. When the processing is finished, the processed copies of the objects replace the original objects. Therefore, you must provide sufficient additional disk space for a second copy of each object to be processed. For example, if you plan to process a whole cube in a single transaction, you need sufficient hard disk space to store a second copy of the whole cube.

Availability Considerations

In an Analysis Services environment, a cube or mining model may be unavailable for querying because of a hardware or software failure. A cube also may be unavailable because it needs to be processed.

Providing Availability in the Event of Hardware or Software Failures

Hardware or software may fail for various reasons. However, maintaining availability of your Analysis Services installation is not only about troubleshooting the source of those failures, but also about providing alternative resources that enable the user to continue using the system if a failure occurs. Clustering and load balancing servers are typically used to provide the alternative resources that are necessary to maintain availability when hardware or software failures occur.

To provide availability in the event of a hardware or software failure, consider deploying Analysis Services into a failover cluster. In a failover cluster, if the primary node fails for any reason or if it must be rebooted, Microsoft Windows Clustering fails over to a secondary node. After the failover, which occurs very quickly, when users run query they are accessing the instance of Analysis Services that is running on the secondary node. For more information about failover clusters, see [Windows Server Technologies: Failover Clusters](#).

Another solution for availability issues is to deploy your Analysis Services project onto two or more production servers. You can then use the Network Load Balancing (NLB) feature of Windows servers to combine the production servers into a single cluster. In an NLB cluster, if a server in the cluster is unavailable due to hardware or software issues, the NLB service directs user queries to those servers that are still available.

Providing Availability While Processing Structural Changes

Certain changes to a cube can cause the cube to be unavailable until it is processed. For example, if you make structural changes to a dimension in a cube, even if you reprocess the dimension, each cube that uses the modified dimension must also be processed. Until you process those cubes, users cannot query them, nor can they query any mining models that are based on a cube that has the modified dimension.

To provide availability while you process structural changes that may affect one or more cubes in an Analysis Services project, consider incorporating a staging server and using the Synchronize Database Wizard. This feature lets you update data and metadata on a staging server, and then to perform an online synchronization of the production server and the staging server. For more information, see [Synchronize Analysis Services Databases](#).

To transparently process incremental updates to source data, enable proactive caching. Proactive caching updates cubes with new source data without requiring manual processing and without affecting the availability of cubes. For more information, see [Proactive Caching \(Partitions\)](#).

Scalability Considerations

Multiple instances of Microsoft SQL Server and Analysis Services on the same computer may cause performance

issues. To solve these issues, one option may be to increase the processor, memory, and disk resources on the server. However, you may also need to scale the instances of SQL Server and Analysis Services across multiple computers.

Scaling Analysis Services Across Multiple Computers

There are several ways to scale an installation of Analysis Services across multiple computers. These options are described in the following list.

- If there are multiple instances of Analysis Services on a single computer, you can move one or more instances to another computer.
- If there are multiple Analysis Services databases on a single computer, you can move one or more of the databases onto its own instance of Analysis Services on a separate computer.
- If one or more relational databases provide data to an Analysis Services database, you can move these databases to a separate computer. Before you move the databases, consider the network speed and bandwidth that exist between the Analysis Services database and its underlying databases. If the network is slow or congested, moving the underlying databases to a separate computer will degrade processing performance.
- If processing affects query performance, but you can't process during times of reduced query load, consider moving your processing tasks to a staging server and then performing an online synchronization of the production server and the staging server. For more information, see [Synchronize Analysis Services Databases](#). You can also distribute processing across multiple instances of Analysis Services by using remote partitions. Processing remote partitions uses the processor and memory resources on the remote server, instead of the resources on the local computer. For information on remote partitions management, see [Create and Manage a Remote Partition \(Analysis Services\)](#).
- If query performance is poor but you cannot increase the processor and memory resources on the local server, consider deploying an Analysis Services project onto two or more production servers. Then you can use Network Load Balancing (NLB) to combine the servers into a single cluster. In an NLB cluster, queries are automatically distributed across all the servers in the NLB cluster.

Deploy Model Solutions Using XMLA

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In SQL Server Management Studio, the **CREATE To** option of the **Script Database As** command creates an XML script of an entire Microsoft SQL Server Analysis Services database or one of its constituent objects. The resulting script can then be run on another computer to recreate the schema (metadata) of the Analysis Services database. The script generates the entire database, and there is no mechanism for incrementally updating already deployed objects when using the script. After running the script and deploying the database, the newly created database must be processed before users can browse it.

For more information about the **Script Database As** command, see [Document and Script an Analysis Services Database](#).

Modifying Object Properties in the XML Script

When using the **Script Database As** command, you cannot modify specific properties (such as the database name, data source connection strings, and security settings) of the database objects. These properties must either be manually modified in the script after the script has been generated or modified in the deployed database after running the script.

IMPORTANT

The XML script will not contain the password if this is specified in either the connection string for a data source or for impersonation purposes. Since the password is required for processing purposes in this scenario, you will either need to add this manually to the XML script before it executes or add it after the XML script executes.

[Synchronize Analysis Services Databases](#)

Deploy Model Solutions Using the Deployment Wizard

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard uses JSON output files generated from a Microsoft SQL Server Analysis Services project as input files. These input files are easily modifiable to customize the deployment of an Analysis Services project. The generated deployment script can then either be immediately run or saved for later deployment.

NOTE

The Analysis Services Deployment Wizard/Utility is installed with [SQL Server Management Studio \(SSMS\)](#). Be sure you're using the latest version. If running from the command prompt, by default, the latest version of the deployment wizard is installed to C:\Program Files (x86)\Microsoft SQL Server\140\Tools\Binn\ManagementStudio.

You can deploy by using the wizard as discussed here. You can also automate deployment or use the Synchronize capability. If the deployed database is large, consider using partitions on target systems. You can automate partition creation and population by using Tabular Object Model (TOM), Tabular Model Scripting Language (TMSL), and Analysis Management Objects (AMO).

IMPORTANT

Neither the output files nor the deployment script will contain the user id or password if these are specified in either the connection string for a data source or for impersonation purposes. Since these are required for processing purposes in this scenario, you will add this information manually. If the deployment will not include processing, you can add this connection and impersonation information as needed after deployment. If the deployment will include processing, you can either add this information within the wizard or in the deployment script after it is saved.

In This Section

The following topics describe how to work with the Analysis Services Deployment Wizard, the input files, and the deployment script:

| TOPIC | DESCRIPTION |
|--|--|
| Running the Analysis Services Deployment Wizard | Describes the various ways in which you can run the Analysis Services Deployment Wizard. |
| Understanding the Input Files Used to Create the Deployment Script | Describes which files the Analysis Services Deployment Wizard uses as input values, what each of those files contains, and provides links to topics that describe how to modify the values in each of the input files. |
| Understanding the Analysis Services Deployment Script | Describes what the deployment script contains and how the script runs. |

[Understanding the Input Files Used to Create the Deployment Script](#)

[Deploy Model Solutions with the Deployment Utility](#)

Running the Analysis Services Deployment Wizard

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard can be run the following ways:

- **Interactively** When run interactively, the Analysis Services Deployment Wizard generates a deployment script based on the input files, as modified interactively by user input. The wizard applies any user modifications only to the deployment script. The wizard does not modify the input files. For more information about the input files, see [Understanding the Input Files Used to Create the Deployment Script](#).
- **From the command prompt** When run at the command prompt, the Analysis Services Deployment Wizard generates a deployment script based upon the switches that you use to run the wizard. The wizard may any one of the following: prompt you for user input and modify input files based on that input; run a silent, unattended deployment using the input files as is; or create a deployment script that you can use later.

Running the Analysis Services Deployment Wizard Interactively

When you run interactively, the Analysis Services Deployment Wizard reads the values from the input files and presents this information to you. You can modify these input values—such as deployment destination, configuration settings, deployment options, and connection string passwords—or leave them as is. If you change any input values, the wizard uses these changes when generating the deployment script. However, the wizard does not make any changes to the values in the input file.

NOTE

If you want to have the Analysis Services Deployment Wizard modify the input values, run the wizard at the command prompt and set the wizard to run in answer file mode.

After you review the input values and make any wanted changes, the wizard generates the deployment script. You can run this deployment script immediately on the destination server or save the script for later use.

To run the Analysis Services Deployment Wizard interactively

- Click **Start > Microsoft SQL Server > Deployment Wizard**.
-or-
- In the **Projects** folder of the Analysis Services project, double-click the <project name>.asdatabase file.

NOTE

If you cannot find the .asdatabase file, try using Search and specify *.asdatabase. Or, you may need to build the project in SSDT.

Running the Analysis Services Deployment Wizard at the Command Prompt

The Analysis Services Deployment Wizard can also be run at the command prompt. When you run the wizard at the command prompt, you provide the full path to the .asdatabase file and run the wizard in one of the following

modes:

Answer file mode

In answer file mode, the wizard lets you interactively modify the input files that were originally generated when the Analysis Services project was built in Visual Studio with Analysis Services projects. The wizard saves these modified input files before generating the deployment script. The modified input files become the new starting point the next time that the wizard is run.

To run the wizard in answer file mode, use the **/a** switch.

Silent mode

In silent mode, the wizard runs a silent, unattended deployment based on the information resident in the input files.

To run the wizard in silent mode, use the **/s** switch. When you run the wizard in silent mode, messages are output to the console or to a log file if one is provided.

Output mode

In output mode, the wizard generates a deployment script for later execution based on the input files.

To run the wizard in output mode, use the **/o** switch and provide an output file name.

For more information about these command line switches, see [Deploy Model Solutions with the Deployment Utility](#).

The following procedure describes how to run the Analysis Services Deployment Wizard at the command prompt.

To run the Analysis Services Deployment Wizard at the command prompt

1. Open a command prompt and navigate to the C:\Program Files (x86)\Microsoft SQL Server\140\Tools\Binn\ManagementStudio
2. Type **Microsoft.AnalysisServices.Deployment.exe** followed by the switches that correspond to the mode in which you want to run the wizard.

[Deploy Model Solutions Using the Deployment Wizard](#)

Deployment Script Files - Input Used to Create Deployment Script

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you build a Microsoft SQL Server Analysis Services project, Visual Studio with Analysis Services projects generates files for the project. Visual Studio with Analysis Services projects puts these files in the Output folder of the Analysis Services project. By default output is out in the \Bin folder. The following table lists the XML files that Visual Studio with Analysis Services projects creates.

| FILE | DESCRIPTION |
|---|--|
| <code><project name>.asdatabase</code> | An XMLA file for Multidimensional or 1100/1103 Tabular model projects, or a JSON file for Tabular 1200 and higher model projects. Contains the declarative definitions for all the Analysis Services objects in the project. |
| <code><project name>.deploymenttargets</code> | Contains the name of the Analysis Services instance and database in which the Analysis Services objects will be created. |
| <code><project name>.configsettings</code> | Contains environment specific settings, such as data source connection information and object storage locations. Settings in this file override settings in the <code><project name>.asdatabase</code> file. |
| <code><project name>.deploymentoptions</code> | Contains deployment options, such as whether deployment is transactional and whether deployed objects should be processed after deployment. |

NOTE

Visual Studio with Analysis Services projects never stores passwords in its project files.

Modifying the Input Files

Modifying the values in the input files, or the values retrieved from the input files, makes it possible to change the deployment destination, the configuration settings, and deployment options without editing the whole `<project name>.asdatabase` file (or a whole script file if you generate a script from an existing Analysis Services database). Being able to modify individual files lets you easily create different deployment scripts for different purposes.

The following topics explain how to modify values in the various input files:

- [Specifying the Installation Target](#)
- [Specifying Partition and Role Deployment Options](#)
- [Specifying Configuration Settings for Solution Deployment](#)
- [Specifying Processing Options](#)

[Understanding the Analysis Services Deployment Script](#)

Deployment Script Files - Specifying the Installation Target

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard reads the installation target information from the `<project name>.deploymenttargets` file. Visual Studio with Analysis Services projects creates this file when you build the Microsoft SQL Server Analysis Services project. Visual Studio with Analysis Services projects uses the database and server specified on the **Deployment** page of the `<project name> Properties Pages` dialog box to create the `<project name>.targets` file.

Modifying the Installation Target for Deployment

In some situations, you may need to deploy an Analysis Services project to a database or Analysis Services instance that is different than the one specified on the **Deployment** page. For example, you may want to deploy the project to a server for testing before deployment, and then deploy it to a production server after testing is finished. You may also want to deploy a completed and tested project to multiple production servers in a Network Load Balancing cluster, or to a staging server and a production server.

To deploy an Analysis Services project to a different database or Analysis Services instance, you can change the installation target in the input file by using one of the methods described in the following procedure.

To change the installation target after the input files have been generated

- Run the Analysis Services Deployment Wizard interactively. On the **Installation Target** page, specify a new destination for the Analysis Services instance and database.

-or-
- Run the Analysis Services Deployment Wizard at the command prompt and set the wizard to run in answer file mode. For more information about answer file mode, see [Running the Analysis Services Deployment Wizard](#).

-or-
- Modify the `<project name>.deploymenttargets` file by using any text editor.

[Specifying Partition and Role Deployment Options](#)

[Specifying Configuration Settings for Solution Deployment](#)

[Specifying Processing Options](#)

Deployment Script Files - Partition and Role Deployment Options

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard reads the partition and role deployment options from the *<project name>.deploymentoptions* file. Visual Studio with Analysis Services projects creates this file when you build the Microsoft SQL Server Analysis Services project. Visual Studio with Analysis Services projects uses the partition and role deployment options of the current project when the *<project name>.deploymentoptions* file is created. For more information about configuration settings, see [Understanding the Input Files Used to Create the Deployment Script](#).

Reviewing the Partition and Role Deployment Options

The deployment options in the *<project name>.deploymentoptions* file include the following:

Partition deployment options

The *<project name>.deploymentoptions* file specifies whether existing partitions in the destination database are retained or overwritten (default). If existing partitions are retained, only new partitions will be deployed, and the partitions and aggregation designs on all existing measure groups are left unchanged.

NOTE

If the measure group in which the partition exists is deleted, the partition is automatically deleted.

Role deployment options

The *<project name>.deploymentoptions* file specifies one of the following role deployment options:

- Existing roles and role members in the destination database are retained, and only new roles and role members are deployed.
- All existing roles and members in the destination database are replaced by the roles and members being deployed.
- Existing roles and role members in the destination database are retained, and no new roles are deployed.
- **Note** When existing roles and members are retained, the permissions associated with those roles are reset to none. Security permissions are contained by the objects they secure, not by the security roles with which they are associated. For more information about how to work with this behavior by using the Analysis Service Deployment Wizard, see 'Retain Roles and Members' in the Microsoft Knowledge Base.

Modifying the Partition and Role Deployment Options

You may have to deploy the Analysis Services project using different partition and role options than those stored in the *<project name>.deploymentoptions* file. For example, you may want to retain existing partitions, roles, and role members, instead of replacing all existing partitions, roles, and members as indicated in the *<project name>.deploymentoptions* file.

To modify the deployment of partitions and roles in an Analysis Services project, you cannot change the partition and roles settings within the project because the *<project name> Properties Pages* dialog box in Visual Studio

with Analysis Services projects does not display these options. If you want to change the deployment options for roles and partitions, you must change this information within the *<project name>.deploymentoptions* file itself. The following procedure describes how to change the partition and role deployment options within the *<project name>.deploymentoptions* file.

To change the deployment of partitions or roles after the input files have been generated

- Run the Analysis Services Deployment Wizard interactively, and on the **Partition and Role Deployment Options** page, specify new deployment options for the partitions and roles.

-or-

- Run the Analysis Services Deployment Wizard at the command prompt, and set the wizard to run in answer file mode. (For more information about answer file mode, see [Running the Analysis Services Deployment Wizard](#).)

-or-

- Open the *<project name>.deploymentoptions* in any text editor and manually change the options. The options for PartitionDeployment are DeployPartitions, RetainPartitions. The options for RoleDeployment are DeployRolesAndMembers, DeployRolesRetainMembers, RetainRoles.

[Specifying Processing Options](#)

Deployment Script Files - Solution Deployment Config Settings

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard reads the partition and role deployment options that you use in the deployment script from the *<project name>.configsettings* file. Visual Studio with Analysis Services projects creates this file when you build the Microsoft SQL Server Analysis Services project. Visual Studio with Analysis Services projects uses the configuration settings of the current project to create the *<project name>.configsettings* file.

Reviewing the Configuration Settings for Deployment

The following are the configuration settings stored in the *<project name>.configsettings* file:

- **Data Source Connection Strings** These are the connection strings for each data source based on the values specified in the Analysis Services project. The user id and password are always removed from the connection string before the remainder of the string is stored in this file. However, if the Deployment Wizard is deploying directly to an Analysis Services instance, you can add the appropriate user id and password information within the wizard to enable a successful processing of the deployment database. This connection information will not be stored in the deployment script itself if one is saved by the Deployment Wizard.
- **Impersonation Accounts** This setting specifies the user name that Analysis Services uses to run statements in each data source. If no impersonation account is specified, Analysis Services uses its logon account to run statements. If the Analysis Services logon account is granted permissions directly in the data source, all database administrators in all databases in the Analysis Services instance have access to the data source through the logon account. If a user account and password is specified, this information is always removed before the impersonation information is stored in this file. However, if the Deployment Wizard is deploying directly to an Analysis Services instance, you can add the appropriate user id and password information within the wizard to enable a successful processing of the deployment database. This impersonation information will not be stored in the deployment script itself if one is saved by the Deployment Wizard.
- **Key Error Log Files** This setting specifies the file name and path of the key error log file for each cube, measure group, partition, and dimension in the database.
- **Storage Locations** This setting specifies the storage location for each cube, measure group, and partition in the database. If no value is provided for an object, the Analysis Services Deployment Wizard uses the default location for the object. For example, partitions use the location for the measure group, measure groups use the location for the cube, and cubes use the default location for objects on the Analysis Services instance. The storage location can be a local or a Universal Naming Convention (UNC) path.
- **Report Server** This setting specifies the report server and folder location for each report action defined in each cube in the database.

Modifying the Configuration Settings for Deployment

In some cases, you may need to deploy the Analysis Services project using different configuration settings than those stored in the *<project name>.configsettings* file. For example, you may want to change the connection

string to one or more data sources, or specify storage locations for specific partitions or measure groups.

To modify the deployment of partitions and roles in an Analysis Services project, you must change this information within the *<project name>.configsettings* file, as described in the procedure below. You cannot change the partition and roles settings within the project because the *<project name> Properties Pages* dialog box in Visual Studio with Analysis Services projects does not display these options.

NOTE

Configuration settings can apply to all objects or only to newly created objects. Apply configuration settings to newly created objects only when you are deploying additional objects to a previously deployed Analysis Services database and do not want to overwrite existing objects. To specify whether configuration settings apply to all objects or only to newly created ones, set this option in the *<project name>.deploymentoptions* file. For more information, see [Specifying Partition and Role Deployment Options](#).

To change configuration settings after the input files have been generated

- Run the Analysis Services Deployment Wizard interactively, and on the **Configuration Settings** page, specify the configuration setting for the objects being deployed.
-or-
- Run the Analysis Services Deployment Wizard at the command prompt and set the wizard to run in answer file mode. For more information about answer file mode, see [Running the Analysis Services Deployment Wizard](#).
-or-
- Modify the *<project name>.configsettings* file by using any text editor.

[Specifying Processing Options](#)

Deployment Script Files - Specifying Processing Options

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The Analysis Services Deployment Wizard reads the processing options from the `<project name>.deploymentoptions` file. Visual Studio with Analysis Services projects creates this file when you build the Microsoft SQL Server Analysis Services project. Visual Studio with Analysis Services projects uses the processing options specified on the **Deployment** page of `<project name> Properties Pages` dialog box to create the `<project name>.deploymentoptions` file.

Reviewing the Processing Options for Deployment

The configuration settings stored within the `<project name>.deploymentoptions` file are as follows:

- **Processing Method** This setting controls whether the deployed objects are processed after deployment and the type of processing that will be performed. There are three processing options:
 - Default processing (default) detects the process state of database objects, and performs processing necessary to deliver unprocessed or partially processed objects to a fully processed state.
 - Full processing processes an object and all the objects that it contains. When Process Full is executed against an object that has already been processed, Analysis Services drops all data in the object, and then processes the object.
 - None means no processing is performed.
- **Writeback Table Options** If writeback is enabled in the Analysis Services project, this setting defines how writeback is handled. There are three writeback table options:
 - By default, if a writeback table exists, it will be used. If a writeback table does not exist, a new writeback table will be created.
 - If a writeback table already exists, the deployment fails. If a writeback table does not exist, a new writeback table will be created.
 - Regardless of whether a writeback table already exists, a new writeback table will be created. In this case, the Analysis Services Deployment Wizard will delete any existing table and replace it with a new writeback table.
- **Transactional Deployment** This setting controls whether the deployment of metadata changes and process commands occurs in a single transaction or in separate transactions.
 - If this option is **True** (default), Analysis Services deploys all metadata changes and all process commands within a single transaction.
 - If this option is **False**, Analysis Services deploys the metadata changes in a single transaction, and deploys each processing command in its own transaction.

Modifying the Processing Options for Deployment

However, you may need to deploy the Analysis Services project using different processing options than those

stored in the *<project name>.deploymentoptions* file. For example, you may want to have all objects fully processed, or processed using the default processing option, or have no processing occur. If the cubes or dimensions are write-enabled, you can specify whether a new or existing writeback table be used.

To modify the processing options used during deployment, you can either edit and rebuild the project, or change the processing options in the input file by using one of the methods as described in the following procedure.

To change processing options after the input files have been generated

- Run the Analysis Services Deployment Wizard interactively. On the **Processing Options** page, specify the processing options for the project being deployed.

-or-

- Run the Analysis Services Deployment Wizard at the command prompt and set the wizard to run in answer file mode. For more information about answer file mode, see [Running the Analysis Services Deployment Wizard](#).

-or-

- Modify the *<project name>.deploymentoptions* file by using any text editor.

[Specifying Configuration Settings for Solution Deployment](#)

Understanding the Analysis Services Deployment Script

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The XMLA deployment script generated by the Analysis Services Deployment Wizard consists of two sections:

- The first part of the deployment script contains the commands required to create, alter, or delete the appropriate Microsoft SQL Server objects in the destination database. By default, the input files generated by the Analysis Services project are based on an incremental deployment. As a result, the XMLA deployment script will only affect those objects that were changed or deleted.
- The second part of the deployment script contains the commands required to process only the objects created or altered on the destination server (the Process Default option) or to fully process the destination database. You can also choose to have the deployment script contain no processing commands.

The entire deployment script can execute in a single transaction or in multiple transactions. If the script executes in multiple transactions, the first part of the script executes as a single transaction, and each object is processed in its own transaction.

IMPORTANT

The Analysis Services Deployment Wizard only deploys objects into a single Analysis Services database. It does not deploy any server level objects or data.

[Understanding the Input Files Used to Create the Deployment Script](#)

Deploy Model Solutions with the Deployment Utility

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The **Microsoft.AnalysisServices.Deployment** utility lets you start the Microsoft SQL Server Analysis Services deployment engine from the command prompt. As input file, the utility uses the XML output files generated by building an Analysis Services project in Visual Studio with Analysis Services projects. The input files are easily modifiable to customize the deployment of an Analysis Services project. The generated deployment script can then either be immediately run or saved for later deployment.

NOTE

The Analysis Services Deployment Wizard/Utility is installed with [SQL Server Management Studio \(SSMS\)](#). Be sure you're using the latest version. By default, the latest version of the deployment wizard is installed to C:\Program Files (x86)\Microsoft SQL Server\140\Tools\Binn\ManagementStudio.

Syntax

```
Microsoft.AnalysisServices.Deployment [ASdatabasefile]
  {[/s[:logfile]] | [/a] | [[/o[:output_script_file]] [/d]]}
```

Arguments

ASdatabasefile

The full path of the folder in which the Analysis Services deployment script (.asdatabase) file is located. This file is generated when you deploy a project in Visual Studio with Analysis Services projects. It is located in the project bin folder. The .asdatabase file contains the object definitions to be deployed is located. If not specified, the current folder is used.

/s

Runs the utility in silent mode and not display any dialog boxes. For more information about modes, see the section, [Modes](#), later in this topic.

logfile

The full path and file name of the log file. Trace events will be logged to the specified log file. If the log file already exists, the file's content will be replaced.

/a

Runs the utility in answer mode. All responses made during the wizard part of the utility should be written back to the input files, but no changes will actually be made to the deployment targets.

/o

Runs the utility in output mode. Deployment will not occur, but the XML for Analysis (XMLA) script that would ordinarily be sent to the deployment targets is instead saved to the specified output script file. If *output_script_file* is not specified, the utility tries to use the output script file specified in the deployment options (.deploymentoptions) input file. If an output script file is not specified in the deployment options input file, an error occurs.

For more information about modes, see the section, [Modes](#), later in this topic.

output_script_file

The full path and file name of the output script file.

/d

If the **/o** argument is used, specifies that the utility should not connect to the target instance. Because no connection is made to the deployment targets, the output script is generated based only on information retrieved from the input files.

NOTE

The **/d** argument is used only in output mode. This argument is ignored if specified in answer or silent mode. For more information about modes, see the section, [Modes](#), later in this topic.

Remarks

The **Microsoft.AnalysisServices.Deployment** utility takes a set of files that provide the object definitions, deployment targets, deployment options, and configuration settings, and tries to deploy the object definitions to the specified deployment targets, using the specified deployment options and configuration settings. This utility can provide a user interface when invoked in answer file or output mode. For more information about how to use the user interface supplied for this utility to create answer files, see [Deploy Model Solutions Using the Deployment Wizard](#).

The utility is located in the `\Program files (x86)\Microsoft SQL Server\140\Binn\ManagementStudio` folder.

Modes

The utility can be run in the modes listed in the following table.

| MODE | DESCRIPTION |
|-------------|--|
| Silent mode | No user interface is displayed and all information needed for deployment is supplied by the input files. No progress is displayed by the utility in silent mode. Instead, an optional log file can be used to capture progress and error information for later review. |
| Answer mode | The Deployment Wizard user interface is displayed and user responses are saved to the specified input files for later deployment. Deployment does not occur in answer mode. The only purpose of answer mode is to capture user responses |
| Output mode | No user interface is displayed and all information needed for deployment is supplied by the input files.

However, unlike silent mode, the output from the utility is written to an output script file, not sent to the deployment targets indicated in the input files. Unless the /d argument is specified, the utility connects with each deployment target to compare metadata while generating the output script file. |

[Back to Arguments](#)

Examples

The following example shows how to deploy an Analysis Services project in silent mode, logging progress and error messages for later review:

```
Microsoft.AnalysisServices.Deployment.exe
```

```
<drive>:\My Documents\Visual Studio 2010\Projects\AdventureWorksProject\Project1\bin
```

```
/s: C:\ My Documents\Visual Studio 2010\Projects\AdventureWorksProject\Project1\bin\deployment.log
```

[Command Prompt Utility Reference \(Database Engine\)](#)

Multidimensional Model Databases (SSAS)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

An Analysis Services database is a collection of data sources, data source views, cubes, dimensions, and roles. Optionally, an Analysis Services database can include structures for data mining, and custom assemblies that provide a way for you to add user-defined functions to the database.

Cubes are the fundamental query objects in Analysis Services. When you connect to an Analysis Services database via a client application, you connect to a cube within that database. A database might contain multiple cubes if you are reusing dimensions, assemblies, roles, or mining structures across multiple contexts.

You can create and modify a Analysis Services database programmatically or by using one of these interactive methods:

- Deploy an Analysis Services project from Visual Studio with Analysis Services projects to a designated instance of Analysis Services. This process creates an Analysis Services database, if a database with that name does not already exist within that instance, and instantiates the designed objects within the newly created database. When working with an Analysis Services database in Visual Studio with Analysis Services projects, changes made to objects in the Analysis Services project take effect only when the project is deployed to an Analysis Services instance.
- Create an empty Analysis Services database within an instance of Analysis Services, by using either SQL Server Management Studio or Visual Studio with Analysis Services projects, and then connect directly to that database using Visual Studio with Analysis Services projects and create objects within it (rather than within a project). When working with an Analysis Services database in this manner, changes made to objects take effect in the database to which you are connecting when the changed object is saved.

Visual Studio with Analysis Services projects uses integration with source control software to support multiple developers working with different objects within an Analysis Services project at the same time. A developer can also interact with an Analysis Services database directly, rather than through an Analysis Services project, but the risk of this is that the objects in an Analysis Services database can become out of sync with the Analysis Services project that was used for its deployment. After deployment, you administer an Analysis Services database by using SQL Server Management Studio. Certain changes can also be made to an Analysis Services database by using SQL Server Management Studio, such as to partitions and roles, which can also cause the objects in an Analysis Services database to become out of sync with the Analysis Services project that was used for its deployment.

Attach and Detach Analysis Services Databases

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are often situations when an Analysis Services database administrator (dba) wants to take a database offline for a period, and then bring that database back online on the same server instance, or on a different one. These situations are often driven by business needs, such as moving the database to a different disk for better performance, gaining room for database growth, or to upgrade a product. For all those cases and more, the **Attach** and **Detach** commands enable the Analysis Services dba to take the database offline and bring it back online with little effort.

Attach and Detach commands

The **Attach** command enables you to bring online a database that was taken offline. You can attach the database to the original server instance, or to another instance. When you attach a database the user can specify the **ReadWriteMode** setting for the database. The **Detach** command enables you to take offline a database from the server.

Attach and Detach Usage

The **Attach** command is used to bring online an existing database structure. If the database is attached in **ReadWrite** mode, it can be attached only one time to a server instance. However, if the database is attached in **ReadOnly** mode, it can be attached multiple times to different server instances. However, the same database cannot be attached more than one time to the same server instance. An error is raised when an attempt is made to attach the same database more than one time, even if the data has been copied to separate folders.

IMPORTANT

If a password was required to detach the database, the same password is required to attach the database.

The **Detach** command is used to take offline an existing database structure. When a database is detached, you should provide a password to protect confidential metadata.

IMPORTANT

To protect the content of the data files, you should use an access control list for the folder, subfolders, and data files.

When you detach a database, the server follows these steps.

| DETACHING A READ/WRITE DATABASE | DETACHING A READ-ONLY DATABASE |
|---|--|
| <p>1) The server issues a request for a CommitExclusive Lock on the database</p> <p>2) The server waits until all ongoing transactions are either committed or rolled back</p> <p>3) The server builds all the metadata that it must have to detach the database</p> <p>4) The database is marked as deleted</p> <p>5) The server commits the transaction</p> | <p>1) The database is marked as deleted</p> <p>2) The server commits the transaction</p> <p>Note: The detaching password cannot be changed for a read-only database. An error is raised if the password parameter is provided for an attached database that already contains a password.</p> |

The **Attach** and **Detach** commands must be executed as single operations. They cannot be combined with other operations in the same transaction. Also, the **Attach** and **Detach** commands are atomic transactional commands. This means the operation will either succeed or fail. No database will be left in an uncompleted state.

IMPORTANT

Server or database administrator privileges are required to execute the **Detach** command.

IMPORTANT

Server administrator privileges are required to execute the **Attach** command.

Backup and Restore of Analysis Services Databases

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Analysis Services includes backup and restore so that you can recover a database and its objects from a particular point in time. Backup and restore is also a valid technique for migrating databases to upgraded servers, moving databases between servers, or deploying a database to a production server. For the purposes of data recovery, if you do not already have a backup plan and your data is valuable, you should design and implement a plan as soon as possible.

The backup and restore commands are performed on a deployed Analysis Services database. For your projects and solutions in Visual Studio with Analysis Services projects, you should use source control to ensure you can recover specific versions of your source files, and then create a data recovery plan for the repository of the source control system you are using.

For a full backup that includes source data, you have to back up the database which contains detail data. Specifically, if you are using ROLAP or DirectQuery database storage, detail data is stored in an external SQL Server relational database that is distinct from the Analysis Services database. Otherwise, if all objects are tabular or multidimensional, the Analysis Services backup will include both the metadata and source data.

One clear benefit of automating backup is that the data snapshot will always be as up-to-date as the automated frequency of backup specifies. Automated schedulers ensure that backups are not forgotten. Restoring a database can also be automated, and can be a good way to replicate data, but be sure to back up the encryption key file on the instance you replicate to. The synchronization feature is dedicated to replication of Analysis Services databases, but only for the data that is out of date. All of the features mentioned here can be implemented through the user interface, by way of XML/A commands or programmatically run through AMO.

This topic includes the following sections:

- [Preparing for Backup](#)
- [Backing Up a Multidimensional or a Tabular Database](#)
- [Restoring an Analysis Services Database](#)

Prerequisites

You must have administrative permissions on the Analysis Services instance or Full Control (Administrator) permissions on the database you are backing up.

Restore location must be an Analysis Services instance that is the same version, or a newer version, as the instance from which the backup was taken. Although you cannot restore a database from a SQL Server 2017 instance to an earlier version of Analysis Services, it is common practice to restore an older version database, such as SQL Server 2012, on a newer SQL Server 2017 instance.

Restore location must be the same server type. Tabular databases can only be restored to Analysis Services running in tabular mode. Multidimensional databases require an instance running in multidimensional mode.

Preparing for Backup

Use the following checklist to prepare for backup:

- Check the location where the backup file will be stored. If you are using a remote location, you must

specify it as a UNC folder. Verify that you can access the UNC path.

- Check the permissions on the folder to ensure that the Analysis Services service account has Read/Write permissions on the folder.
- Check for sufficient disk space on the target server.
- Check for existing files of the same name. If a file of the same name already exists, backup will fail unless you specify options to overwrite the file.

Backing Up a Multidimensional or a Tabular Database

Administrators can back up an Analysis Services database to a single Analysis Services backup file (.abf), regardless of size of the database. For step by step instructions, see [How to Backup an Analysis Services Database \(TechMantra\)](#) and [Automate Backup an Analysis Services Database \(TechMantra\)](#).

NOTE

Power Pivot for SharePoint, used for loading and querying Power Pivot data models in a SharePoint environment, loads its models from SharePoint content databases. These content databases are relational and run on the SQL Server relational database engine. As such, there is no Analysis Services backup and restore strategy for Power Pivot data models. If you have a disaster recovery plan in place for SharePoint content, that plan encompasses the Power Pivot data models stored in the content databases.

Remote Partitions

If the Analysis Services database contains remote partitions, the remote partitions should also be backed up. When you back up a database with remote partitions, all the remote partitions on each remote server are backed up to a single file on each of those remote servers respectively. Therefore, if you want to create those remote backups off their respective host computers, you will have to manually copy those files to the designated storage areas.

Contents of a backup file

Backing up an Analysis Services database produces a backup file whose contents vary depending upon the storage mode used by the database objects. This difference in backup content results from the fact that each storage mode actually stores a different set of information within an Analysis Services database. For example, multidimensional hybrid OLAP (HOLAP) partitions and dimensions store aggregations and metadata in the Analysis Services database, while relational OLAP (ROLAP) partitions and dimensions only store metadata in the Analysis Services database. Because the actual contents of an Analysis Services database vary based on the storage mode of each partition, the contents of the backup file also vary. The following table associates the contents of the backup file to the storage mode used by the objects.

| STORAGE MODE | CONTENTS OF BACKUP FILE |
|--|---|
| Multidimensional MOLAP partitions and dimensions | Metadata, source data, and aggregations |
| Multidimensional HOLAP partitions and dimensions | Metadata and aggregations |
| Multidimensional ROLAP partitions and dimensions | Metadata |
| Tabular In-Memory Models | Metadata and source data |
| Tabular DirectQuery Models | Metadata only |

NOTE

Backing up an Analysis Services database does not back up the data in any underlying data sources, such as a relational database. Only the contents of the Analysis Services database are backed up.

When you back up an Analysis Services database, you can choose from the following options:

- Whether to compress all database backups. The default is to compress backups.
- Whether to encrypt the contents of the backup files and require a password before the file can be unencrypted and restored. By default, the backed up data is not encrypted.

IMPORTANT

For each backup file, the user who runs the backup command must have permission to write to the backup location specified for each file. Also, the user must have one of the following roles: a member of a server role for the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be backed up.

For more information about backing up an Analysis Services database, see [Backup Options](#).

Restoring an Analysis Services Database

Administrators can restore an Analysis Services database from one or more backup files.

NOTE

If a backup file is encrypted, you must provide the password specified during backup before you can use that file to restore an Analysis Services database.

During restoration, you have the following options:

- You can restore the database using the original database name, or you can specify a new database name.
- You can overwrite an existing database. If you choose to overwrite the database, you must expressly specify that you want to overwrite the existing database.
- You can choose whether to restore existing security information or skip security membership information.
- You can choose to have the restore command change the restoration folder for each partition being restored. Local partitions can be restored to any folder location that is local to the Analysis Services instance to which the database is being restored. Remote partitions can be restored to any folder on any server, other than the local server; remote partitions cannot become local.

IMPORTANT

For each backup file, the user who runs the restore command must have permission to read from the backup location specified for each file. To restore an Analysis Services database that is not installed on the server, the user must also be a member of the server role for that Analysis Services instance. To overwrite an Analysis Services database, the user must have one of the following roles: a member of the server role for the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be restored.

NOTE

After restoring an existing database, the user who restored the database might lose access to the restored database. This loss of access can occur if, at the time that the backup was performed, the user was not a member of the server role or was not a member of the database role with Full Control (Administrator) permissions.

For more information about restoring an Analysis Services database, see [Restore Options](#).

See Also

[Backing Up, Restoring, and Synchronizing Databases \(XMLA\)](#)

Backup Options

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

There are many ways to back up your Microsoft SQL Server Analysis Services databases and they all require that you have server administrator and database administrator permissions. You can open the **Backup** dialog box in SQL Server Management Studio, select the appropriate options configuration, and then run the backup from the dialog box itself. Or, you can create a script using the settings already specified in the file; the script can then be saved and run as frequently as required.

Backup and Synchronize

If the database is located on a remote instance of Analysis Services, you can use the synchronization feature to back up the database to the local instance. Development builds of a database can be moved into production in this manner. You can also use the conventional, file based, backup and restore to move the development build into production, but synchronization provides additional functionality. For example, you can have security settings which are different for the development and production computers; synchronization will provide you the option to maintain those settings and synchronize all objects other than roles. Also, synchronization typically does an incremental update of those objects which are different for the source and destination computers. This kind of incremental backup is not available using the backup/restore feature. For more information, see [Synchronize Analysis Services Databases](#).

IMPORTANT

The Analysis Services service account must have permission to write to the backup location specified for each file. Also, the user must have one of the following roles: administrator role on the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be backed up.

[Backing Up, Restoring, and Synchronizing Databases \(XMLA\)](#)

Restore Options

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

There are many ways to restore your Microsoft SQL Server Analysis Services databases, all of which require that you have administrator permissions for both the server computer and the Analysis Services database. To restore an Analysis Services database, you can open the **Restore Database** dialog box in SQL Server Management Studio, select the appropriate options configuration and then run the restore from the dialog box. Or, you can create a script using the settings already specified in the file; the script can then be saved and run as often as needed. In this way, the restore is completed by using XMLA, as described in the next section.

Restoring Databases Using XMLA

The XMLA Restore command is a way to automate the restore process by running a restore based on an .abf file. The Restore command has a number of properties that can be set to specify security definitions, where remote partitions should be stored, and the relocation of relational OLAP (ROLAP) objects. For more information, see [Restore Element \(XMLA\)](#).

IMPORTANT

For each backup file, the user who runs the restore command must have permission to read from the backup location specified for each file. To restore an Analysis Services database that is not installed on the server, the user must also be a member of the server role for that Analysis Services instance. To overwrite an Analysis Services database, the user must have one of the following roles: a member of the server role for the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be restored.

NOTE

After restoring an existing database, the user who restored the database might lose access to the restored database. This loss of access can occur if, at the time that the backup was performed, the user was not a member of the server role or was not a member of the database role with Full Control (Administrator) permissions.

Document and Script an Analysis Services Database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

After an Analysis Services database is deployed, you can use SQL Server Management Studio to output the metadata of the database, or of an object contained in the database, as an XML for Analysis (XMLA) script. You can output this script to a new **XMLA Query Editor** window, to a file, or to the Clipboard. For more information about XMLA, see [Analysis Services Scripting Language \(ASSL for XMLA\)](#).

The generated XMLA script uses Analysis Services Scripting Language (ASSL) elements to define the objects contained by the script. If you generated a CREATE script, the resulting XMLA script contains an XMLA **Create** command and ASSL elements that can be used to create the entire Analysis Services database structure on an instance. If you generated an ALTER script, the resulting XMLA script contains an XMLA **Alter** command and ASSL elements that can be used to restore the structure of an existing Analysis Services database to the state of the database at the time the script was created.

You can use the generated XMLA script from an Analysis Services database in many ways, including:

- To maintain a backup script that allows you to recreate all the database objects and permissions.
- To create or update database development code.
- To create a test or development environment from an existing schema.

[Modify or Delete an Analysis Services Database](#)

[Alter Element \(XMLA\)](#)

[Create Element \(XMLA\)](#)

Modify or Delete an Analysis Services Database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can change the name and description of an Analysis Services database before deployment in Visual Studio with Analysis Services projects and after deployment in SQL Server Management Studio. You can also adjust additional settings on an Analysis Services database, depending on the environment.

NOTE

You cannot change database properties using Visual Studio with Analysis Services projects in online mode.

Modifying Databases Using SQL Server Management Studio

Once an Analysis Services database is deployed, you can use SQL Server Management Studio to change the impersonation mode used by Analysis Services when connecting to data sources contained by the database. The impersonation mode allows you to specify the security context used by Analysis Services when attempting to connect to a data source for processing, browsing, or drillthrough purposes.

Modifying Databases Using SQL Server Data Tools

You can use Visual Studio with Analysis Services projects in project mode to modify the translations for the caption and description of an Analysis Services project used to define a database. For more information about using translations in an Analysis Services database, see [Globalization scenarios for Analysis Services](#).

You can also set the aliases and aggregation functions associated with account types used by account attributes in dimensions contained by the database. Aliases allow you to select the business-specific terminology used by your organization for the account types in a chart of accounts. The account types are used by members of an account attribute to indicate how to aggregate measures over each member by using the aggregation functions specified for each account type contained in the database. For more information about account attributes, see [Attributes and Attribute Hierarchies](#).

Deleting Databases

Deleting an existing Analysis Services database deletes the database and all cubes, dimensions, and mining models in the database. You can only delete an existing Analysis Services database in SQL Server Management Studio.

To delete an Analysis Services database

1. Connect to an Analysis Services instance.
2. In **Object Explorer**, expand the node for the connected Analysis Services instance and ensure that the object to be deleted is visible.
3. Right-click the object to be deleted and select **Delete**.
4. In the **Delete Object** dialog box, click **OK**.

See Also

Document and Script an Analysis Services Database

Move an Analysis Services Database

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are often situations when an Analysis Services database administrator (dba) wants to move a multidimensional or tabular model database to a different location. These situations are often driven by business needs, such as moving the database to a different disk for better performance, gaining room for database growth, or to upgrade a product.

A database can be moved in many ways. This document explains the following common scenarios:

- Interactively using SSMS
- Programmatically using AMO
- By script using XMLA

All scenarios require the user to access the database folder and to use a method for moving the files to the desired final destination.

NOTE

Detaching a database without assigning a password to it leaves the database in an unsecured state. We recommend assigning a password to the database to protect confidential information. Also, the corresponding access security should be applied to the database folder, sub-folders, and files to prevent unauthorized access to them.

Procedures

Moving a database interactively using SSMS

1. Locate the database to be moved in the left or right pane of SSMS.
2. Right-click on the database and select **Detach...**
3. Assign a password to the database to be detached, then click **OK** to execute the detach command.
4. Use any operating system mechanism or your standard method for moving files to move the database folder to the new location.
5. Locate the **Databases** folder in the left or right pane of SSMS.
6. Right-click on the **Databases** folder and select **Attach...**
7. In the **Folder** text box, type the new location of the database folder. Alternatively, you can use the browse button (...) to locate the database folder.
8. Select the **ReadWrite** mode for the database.
9. Type the password used in step 3 and click **OK** to execute the attach command.

Moving a database programmatically using AMO

1. In your C# application, adapt the following sample code and complete the indicated tasks.

```
private void MoveDb(Server server, string dbName,  
                    string dbInitialLocation, string dbFinalLocation,
```

```

string dbPassword, ReadWriteMode dbReadWriteMode)

{

//Verify dbInitialLocation exists before continuing

if (server.Databases.ContainsName(dbName))

{

Database db;

//Save current cursor and change cursor to Cursors.WaitCursor

db = server.Databases[dbName];

db.Detach(dbPassword);

//Add your own code to copy the database files to the destination where you intend to attach the database

//Verify dbFinalLocation exists before continuing

server.Attach(dbFinalLocation, dbReadWriteMode, dbPassword);

//Restore cursor to its original

}

}

}

```

1. In your C# application, invoke `MoveDb()` with the necessary parameters.
2. Compile and execute your code to move the database.

Moving a database by script using XMLA

1. Open a new XMLA tab in SSMS.
2. Copy the following script template for XMLA

```

<Detach xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">

<Object>

<DatabaseID>%dbName%</DatabaseID>

<Password>%password%</Password>

</Object>

</Detach>

```

1. Replace `%dbName%` with the name of the database and `%password%` with the password. The % characters are part of the template and must be removed.
2. Execute the XMLA command.
3. Use any operating system mechanism or your standard method for moving files to move the database folder to the new location.
4. Copy the following script template for XMLA in a new XMLA tab

```

<Attach xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">

<Folder>%dbFolder%</Folder>

```

```
<ReadWriteMode xmlns="http://schemas.microsoft.com/analysisservices/2008/engine/100">%ReadOnlyMode%  
</ReadWriteMode>
```

```
</Attach>
```

1. Replace `%dbFolder%` with the complete UNC path of the database folder, `%ReadOnlyMode%` with the corresponding value **ReadOnly** or **ReadWrite**, and `%password%` with the password. The % characters are part of the template and must be removed.
2. Execute the XMLA command.

Rename a Multidimensional Database (Analysis Services)

9/6/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

The manner in which you change the name of a Microsoft SQL Server Analysis Services database depends upon how you connect to the Analysis Services database. To change the name of an existing database, you must connect in online mode. To change the name of the database into which objects in an Analysis Services project will be instantiated, you must connect in project mode.

To change the database name in online mode

1. Using Visual Studio with Analysis Services projects, connect directly to the Analysis Services database.
2. In Solution Explorer, right-click the database and then click **Edit Database**.
3. In the **Database name** text box, change the database name.
4. Click **Save** or **Save All** on the toolbar, click **Save Selected Items** or **Save All** on the **File** menu, or close the **Database Designer** and then click **Save** when prompted.

The database name is updated in the Analysis Services instance and the database object in Solution Explorer is refreshed.

To change the database name in project mode

1. Open the Analysis Services project.
2. In Solution Explorer, right-click the Analysis Services project and then click **Properties**.
3. In the **Property Pages** dialog box, click **Deployment** in the **Configuration Properties** section.
4. Change the **Database** property to the new database name.

The next time the Analysis Services project is deployed, it will be deployed to this new database name. If this database already exists, it will be overwritten.

To change the database name using SQL Server Management Studio

- Right-click the Analysis Services database and edit the Name property.

Compatibility Level of a Multidimensional Database (Analysis Services)

7/16/2019 • 4 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Analysis Services, the database compatibility level property determines the functional level of a database. Compatibility levels are unique to each model type. For example, a compatibility level of **1100** has a different meaning depending on whether the database is multidimensional or tabular.

This topic describes compatibility level for multidimensional databases only. For more information about tabular solutions, see [Compatibility Level for Tabular models in Analysis Services](#).

NOTE

Tabular models have additional database compatibility levels that are not applicable to multidimensional models. Compatibility level **1103** does not exist for multidimensional models. See [What is new for the Tabular model in SQL Server 2012 SP1 and compatibility level](#) for more information about **1103** for tabular solutions.

Compatibility Levels for multidimensional databases

Currently, the only multidimensional database behavior that varies by functional level is string storage architecture. By raising the database compatibility level, you can override the 4 gigabyte maximum limit for string storage of measures and dimensions.

For a multidimensional database, valid values for the **CompatibilityLevel** property include the following:

SETTING	DESCRIPTION
1050	This value is not visible in script or tools, but it corresponds to databases created in SQL Server 2005 (9.x), SQL Server 2008, or SQL Server 2008 R2. Any database that does not have CompatibilityLevel explicitly set is implicitly running at the 1050 level.
1100	This is the default value for new databases that you create in SQL Server 2012 (11.x) or SQL Server 2017. You can also specify it for databases created in earlier versions of Analysis Services to enable the use of features that are supported only at this compatibility level (namely, increased string storage for dimension attributes or distinct count measures that contain string data). Databases that have a CompatibilityLevel set to 1100 get an additional property, StringStoresCompatibilityLevel , that lets you choose alternative string storage for partitions and dimensions.

WARNING

Setting the database compatibility to a higher level is irreversible. After you increase the compatibility level to **1100**, you must continue to run the database on newer servers. You cannot rollback to **1050**. You cannot attach or restore an **1100** database on a server version that is earlier than SQL Server 2012 (11.x) or SQL Server 2017.

Prerequisites

Database compatibility levels are introduced in SQL Server 2012 (11.x). You must have SQL Server 2012 (11.x)Analysis Services or higher to view or set the database compatibility level.

The database cannot be a local cube. Local cubes do not support the **CompatibilityLevel** property.

The database must have been created in a previous release (SQL Server 2008 R2 or earlier) and then attached or restored to a SQL Server 2012 (11.x)Analysis Services or higher server. Databases deployed to SQL Server 2012 are already at **1100** and cannot be downgraded to run at a lower level.

Determine the existing database compatibility level for a multidimensional database

The only way to view or modify the database compatibility level is through XMLA. You can view or modify the XMLA script that specifies your database in SQL Server Management Studio.

If you search the XMLA definition of a database for the property **CompatibilityLevel** and it does not exist, you most likely have a database at the **1050** level.

Instructions for viewing and modifying the XMLA script are provided in the next section.

Set the database compatibility level in SQL Server Management Studio

1. Before raising the compatibility level, backup the database in case you want to reverse your changes later.
2. Using SQL Server Management Studio, connect to the SQL Server 2017Analysis Services server that hosts the database.
3. Right-click the database name, point to **Script Database as**, point to **ALTER to**, and then select **New Query Editor Window**. An XMLA representation of the database will open in a new window.
4. Copy the following XML element:

```
<ddl200:CompatibilityLevel>1100</ddl200:CompatibilityLevel>
```

5. Paste it after the `</Annotations>` closing element and before the `<Language>` element. The XML should look similar to the following example:

```
</Annotations>
<ddl200:CompatibilityLevel>1100</ddl200:CompatibilityLevel>
<Language>1033</Language>
```

6. Save the file.
7. To run the script, click **Execute** on the Query menu or press F5.

Supported Operations that Require the Same Compatibility Level

The following operations require that the source databases share the same compatibility level.

1. Merging partitions from different databases is supported only if both databases share the same compatibility level.
2. Using linked dimensions from another database requires the same compatibility level. For example, if you want to use a linked dimension from a SQL Server 2008 R2 database in a SQL Server 2012 (11.x) database, you must port the SQL Server 2008 R2 database to a SQL Server 2012 (11.x) server and set the compatibility level to **1100**.
3. Synchronizing servers is only supported for servers that share the same version and database compatibility level.

Next Steps

After you increase the database compatibility level, you can set the **StringStoresCompatibilityLevel** property in Visual Studio with Analysis Services projects. This increases string storage for measures and dimensions. For more information about this feature, see [Configure String Storage for Dimensions and Partitions](#).

[Backing Up, Restoring, and Synchronizing Databases \(XMLA\)](#)

Set Multidimensional Database Properties (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are a number of Microsoft SQL Server Analysis Services database properties that you can configure in the Visual Studio with Analysis Services projects database designer.

In this designer, you can perform the following types of tasks:

- If you are connected to the Analysis Services database in online mode, you can change the name of the Analysis Services database. If you are working in project mode, you can change the database name for the next deployment of the project. For more information, see [Rename a Multidimensional Database \(Analysis Services\)](#) and [Configure Analysis Services Project Properties \(SSDT\)](#).
- You can provide a description of the database that can be presented to users. You can also view the name of the database, but cannot change it. To change the database name, you must edit the properties of the project.
- You can provide translations for the database name and description for one or more languages. For more information, see [Cube Translations](#), [Dimension Translations](#), and [Translation support in Analysis Services](#).
- You can view and modify default account type mappings. Account type mappings are used when one or more measures use the *ByAccount* aggregation function. For each account type, you can specify an alias and modify the default aggregation function associated with the account type. For more information modifying the default aggregation, see [Define Semiadditive Behavior](#).

Database Properties

In addition to the above, there are a number of properties of a database that you can configure in the Properties window.

PROPERTY	DESCRIPTION
Aggregation Prefix	The common prefix that can be used for aggregation names for all of the partitions in a database. For more information, see AggregationPrefix Element (ASSL) .
Collation	When the Analysis Services project is deployed to an Analysis Services instance, the database will inherit from the Collation server property unless a different value is provided here.
DataSourceImpersonationInfo	Specifies the default impersonation mode for all data source objects in the database. This is the mode that the Analysis Services service uses when processing objects, synchronizing servers, and executing the OpenQuery and SystemOpenSchema data mining statements.

PROPERTY	DESCRIPTION
Estimated Size	<p>Provides an estimated size of the database files on disk. If data is stored in multiple locations, this estimate will be limited to just the data files stored under the database folder.</p> <p>EstimatedSize can also be used as a basis for estimating memory. Typically, memory requirements are larger than the size of data on disk due to additional data structures that are created when the database is loaded into memory.</p> <p>To further estimate memory requirements, you can also use Task Manager to look at the Analysis Services process memory before and after processing the database and observe the memory utilized as a method for understanding the memory requirements of the database.</p>
Language	<p>When the Analysis Services project is deployed to an Analysis Services instance, the database will inherit from the Language server property unless a different value is provided here.</p>
MasterDataSource ID	<p>Used with remote partitions. For more information, see Remote Partitions.</p>

See Also

[Database Properties Dialog Box \(SSAS - Multidimensional\)](#)

[Configure Analysis Services Project Properties \(SSDT\)](#)

Database Storage Location

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are often situations when an Analysis Services database administrator (dba) wants a certain database to reside outside of the server data folder. These situations are often driven by business needs, such as improving performance or expanding storage. For these situations, the **DbStorageLocation** database property enables the Analysis Services dba to specify the database location in a local disk or network device.

DbStorageLocation database property

The **DbStorageLocation** database property specifies the folder where Analysis Services creates and manages all the database data and metadata files. All metadata files are stored at the **DbStorageLocation** folder, with the exception of the database metadata file, which is stored in the server data folder. There are two important considerations when setting the value of **DbStorageLocation** database property:

- The **DbStorageLocation** database property must be set to an existing UNC folder path or an empty string. An empty string is the default for the server data folder. If the folder does not exist, an error will be raised when you execute a **Create**, **Attach**, or **Alter** command.
- The **DbStorageLocation** database property cannot be set to point to the server data folder or any one of its subfolders. If the location points to the server data folder or any one of its subfolders, an error will be raised when you execute a **Create**, **Attach**, or **Alter** command.

IMPORTANT

We recommend that set your UNC path to use a Storage Area Network (SAN), iSCSI-based network, or a locally attached disk. Any UNC path to a network share or any high latency remote storage solution leads to an unsupported installation.

DbStorageLocation compared to StorageLocation

DbStorageLocation specifies the folder where all the database data and metadata files reside, whereas **StorageLocation** specifies the folder where one or more partitions of a cube reside. **StorageLocation** can be set independently of **DbStorageLocation**. This is an Analysis Services dba decision based on the expected results, and many times the usage of one property or the other will overlap.

DbStorageLocation Usage

The **DbStorageLocation** database property is used as part of a **Create** database command in a **Detach/Attach** database commands sequence, in a **Backup/Restore** database commands sequence, or in a **Synchronize** database command. Changing the **DbStorageLocation** database property is considered a structural change in the database object. This means that all metadata must be recreated and the data reprocessed.

IMPORTANT

You should not change the database storage location by using an **Alter** command. Instead, we recommend that you use a sequence of **Detach/Attach** database commands (see [Move an Analysis Services Database, Attach and Detach Analysis Services Databases](#)).

[Attach Element](#)

[Synchronize Element \(XMLA\)](#)

Database ReadWriteModes

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

There are often situations when an Analysis Services database administrator (dba) wants to change a read/write database to a read-only database, or vice versa. These situations are often driven by business needs, such as sharing the same database folder among several servers for scaling out a solution and improving performance. For these situations, the **ReadWriteMode** database property enables the Analysis Services dba to easily change the database operating mode.

ReadWriteMode database property

The **ReadWriteMode** database property specifies whether the database is in read/write mode or in read-only mode. These are the only two possible values of the property. When the database is in read-only mode, no changes or updates can be applied to the database. However, when the database is in read/write mode, changes and updates can occur. The **ReadWriteMode** database property is defined as a read-only property; it can only be set through an **Attach** command.

When a database is in read-only mode, certain restrictions are in place that affect the ordinary set of allowed operations to the database. See the following table for the restricted operations.

READONLY MODE	RESTRICTED OPERATIONS
<p>XML/A commands</p> <p>Note: An error is raised when you execute any one of these commands.</p>	<p>Create</p> <p>Alter</p> <p>Delete</p> <p>Process</p> <p>MergePartitions</p> <p>DesignAggregations</p> <p>CommitTransaction</p> <p>Restore</p> <p>Synchronize</p> <p>Insert</p> <p>Update</p> <p>Drop</p> <p>Note: Cell writeback is allowed in databases set to read-only; however, the changes cannot be committed.</p>

READONLY MODE	RESTRICTED OPERATIONS
MDX statements	COMMIT TRAN CREATE SESSION CUBE ALTER CUBE ALTER DIMENSION CREATE DIMENSION MEMBER DROP DIMENSION MEMBER ALTER DIMENSION
Note: An error is raised when you execute any one of these statements.	Note: Excel users cannot use the grouping feature in Pivot tables, because that feature is internally implemented by using CREATE SESSION CUBE commands.
DMX statements	CREATE [SESSION] MINING STRUCTURE ALTER MINING STRUCTURE DROP MINING STRUCTURE CREATE [SESSION] MINING MODEL DROP MINING MODEL IMPORT SELECT INTO INSERT UPDATE DELETE
Background operations	Any background operations that would modify the database are disabled. This includes lazy processing and proactive caching.

ReadWriteMode Usage

The **ReadWriteMode** database property is to be used as part of an **Attach** database command. The **Attach** command allows the database property to be set to either **ReadWrite** or **ReadOnly**. The **ReadWriteMode** database property value cannot be updated directly because the property is defined as read-only. Databases are created with the **ReadWriteMode** property set to **ReadWrite**. A database cannot be created in read-only mode.

To switch the **ReadWriteMode** database property between **ReadWrite** and **ReadOnly**, you must issue a sequence of **Detach/Attach** commands.

All database operations, with the exception of **Attach**, keep the **ReadWriteMode** database property in its current state. For example, operations like **Alter**, **Backup**, **Restore**, and **Synchronize** preserve the **ReadWriteMode** value.

NOTE

Local cubes can be created from a read-only database.

Synchronize Analysis Services Databases

7/16/2019 • 10 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Analysis Services includes a database synchronization feature that makes two Analysis Services databases equivalent by copying the data and metadata a database on a source server to a database on a destination server. Use the Synchronize Database feature to accomplish any of the following tasks:

- Deploy a database from a staging server onto a production server.
- Update a database on a production server with the changes made to the data and metadata in a database on a staging server.
- Generate XMLA script that can be run in the future to synchronize the databases.
- In distributed workloads where cubes and dimensions are processed on multiple servers, use database synchronization to merge the changes into a single database.

Database synchronization is initiated on the destination server, pulling data and metadata into a database copy on the source server. If the database does not exist, it will be created. Synchronization is a one-way, one-time operation that concludes once the database is copied. It does not provide real-time parity between the databases.

You can re-sync databases that already exist on source and destination servers to pull the latest changes from a staging server into a production database. Files on the two servers will be compared for changes and those that are different will be updated. An existing database on a destination server remains available while synchronization occurs in the background. Users can continue to query the destination database while synchronization is in progress. After synchronization finishes, Analysis Services automatically switches the users to the newly copied data and metadata, and drops the old data from the destination database.

To synchronize databases, run the Synchronize Database Wizard to immediately synchronize the databases, or use it to generate a synchronization script that you can run later. Either approach can be used to increase the availability and scalability of your Analysis Services databases and cube.

NOTE

The following whitepapers, written for previous versions of Analysis Services, still apply to scalable multidimensional solutions built using SQL Server 2012. For more information, see [Scale-Out Querying with Analysis Services](#) and [Scale-Out Querying for Analysis Services with Read-Only Databases](#)

Prerequisites

On the destination (or target) server from which you initiate database synchronization, you must be a member of the Analysis Services server administrator role. On the source server, your Windows user account must have Full Control permissions on the source database. If you are synchronizing database interactively, remember that synchronization runs under the security context of your Windows user identity. If your account is denied access to specific objects, those objects will be excluded from the operation. For more information about server administrator roles and database permissions, see [Grant server admin rights to an Analysis Services instance](#) and [Grant database permissions \(Analysis Services\)](#).

TCP port 2383 must be open on both servers to allow remote connections between default instances. For more

information about creating an exception in Windows Firewall, see [Configure the Windows Firewall to Allow Analysis Services Access](#).

Both the source and destination servers must be the same version and service pack. Because model metadata is also synchronized, to ensure compatibility the build number for both servers should be the same. The edition of each installation must support database synchronization. In SQL Server 2017, database synchronization is supported in enterprise, developer, and business intelligence editions. For more information about features in each edition, see [Editions and Supported Features for SQL Server 2016](#).

The server deployment mode must be identical on each server. If the database you are synchronizing is multidimensional, both source and destination servers must be configured for multidimensional server mode. For more information about deployment modes, see [Determine the Server Mode of an Analysis Services Instance](#).

Turn off lazy aggregation processing if you are using it on the source server. Aggregations that are processing in the background can interfere with database synchronization. For more information about setting this server property, see [OLAP Properties](#).

NOTE

Database size is a factor in determining whether synchronization is a suitable approach. There are no hard requirements, but if synchronization is too slow, consider synchronizing multiple servers in parallel, as described in this technical paper: [Analysis Services Synchronization Best Practices](#).

Synchronize Database Wizard

Use the Synchronize Database Wizard to perform one-way synchronization from a source to a destination database, or to generate a script that specifies a database synchronization operation. You can synchronize both local and remote partitions during the synchronization process and choose whether to include roles.

The Synchronize Database Wizard guides you through the following steps:

- Select the source instance and database from which to synchronize.
- Select storage locations for local partitions on the destination instance.
- Select storage locations for remote partitions on other destination instances.
- Select the level of security and membership information to copy from the source instance and database to the destination instance.
- Select whether to synchronize immediately or to save the XML for Analysis (XMLA) **Synchronize** command generated by the Synchronize Database Wizard to a script file for later synchronization.

By default, the wizard synchronizes all data and metadata, other than membership in existing security groups. You can also copy all security settings or ignore all security settings when synchronizing the data and metadata.

Run the wizard

1. In SQL Server Management Studio, connect to the instance of Analysis Services that will run the destination database. For example, if you are deploying a database to a production server, you would run the wizard on the production server.
2. In Object Explorer, right-click the **Databases** folder, then click **Synchronize**.
3. Specify the source server and source database. In the Select Database to Synchronize page, in **Source Server** and **Source Database**, type the name of the source server and source database. For example, if you are deploying from a test environment to a production server, the source is the database on the staging server.

Destination Server displays the name of the Analysis Services instance with which the data and metadata from the database selected in **Source database** is synchronized.

Synchronization will occur for source and destination databases that have the same name. If the destination server already has a database that shares the same name as the source database, the destination database will be updated with the metadata and data of the source. If the database does not exist, it will be created on the destination server.

4. Optionally, change location for local partition. Use the **Specify Locations for Local Partitions** page to indicate where local partitions should be stored on the destination server.

NOTE

This page appears only if at least one local partition exists in the specified database.

If a set of partitions are installed on drive C of the source server, the wizard lets you copy this set of partitions to a different location on the destination server. If you do not change the default locations, the wizard deploys the measure group partitions within each cube on the source server to the same locations on the destination server. Similarly, if the source server uses remote partitions, the same remote partitions will be used on the destination server.

The **Locations** option displays a grid listing the source folder, destination folder, and estimated size of the local partitions to be stored on the destination instance. The grid contains the following columns:

Source Folder

Displays the folder name on the source Analysis Services instance that contains the local partition. If the column contains the value "(Default)", the default location for the source instance contains the local partition.

Destination Folder

Displays the folder name on the destination Analysis Services instance into which the local partition is to be synchronized. If the column contains the value, "(Default)", the default location for the destination instance contains the local partition.

Click the ellipsis (...) button to display the **Browse for Remote Folder** dialog box and specify a folder on the destination instance into which the local partitions stored in the selected location should be synchronized.

NOTE

This column cannot be changed for local partitions stored in the default location for the source instance.

Size

Displays the estimated size of the local partition.

The **Partitions in selected location** option displays a grid that describes the local partitions stored in the location on the source Analysis Services instance specified in the **Source Folder** column of the selected row in **Locations**.

Cube

Displays the name of the cube that contains the partition.

Measure Group

Displays the name of the measure group in the cube that contains the partition.

Partition Name

Displays the name of the partition.

Size(Mb)

Displays the size in megabytes (MB) of the partition.

5. Optionally, change location for remote partitions. Use the **Specify Locations for Remote Partitions** page to indicate if remote partitions managed by the specified database on the source server should be synchronized, and to specify a destination Analysis Services instance and database into which the selected remote partitions should be stored.

NOTE

This page appears only if at least one remote partition is managed by the specified database on the source Analysis Services instance.

The **Locations** option displays a grid that lists details about locations in which remote partitions for the source database are stored, including source and destination information and the storage size used by each location, available from the selected database. The grid contains the following columns:

Sync

Select to include a location that contains the remote partitions during synchronization.

NOTE

If this option is not selected for a location, remote partitions that are contained in that location will not be synchronized.

Source Server

Displays the name of the Analysis Services instance that contains remote partitions.

Source Folder

Displays the folder name on the Analysis Services instance that contains remote partitions. If the column contains the value "(Default)", the default location for the instance displayed in **Source Server** contains remote partitions.

Destination Server

Displays the name of the Analysis Services instance into which the remote partitions stored in the location specified in **Source Server** and **Source Folder** should be synchronized.

Click the ellipsis (...) button to display the **Connection Manager** dialog box and specify an Analysis Services instance into which the remote partitions stored in the selected location should be synchronized.

Destination Folder

Displays the folder name on the destination Analysis Services instance into which the remote partition is to be synchronized. If the column contains the value, "(Default)", the default location for the destination instance should contain the remote partition.

Click the ellipsis (...) button to display the **Browse for Remote Folder** dialog box and specify a folder on the destination instance into which the remote partitions stored in the selected location should be synchronized.

Size

Displays the estimated size of remote partitions stored in the location.

The **Partitions in selected location** displays a grid that describes the remote partitions stored in the location on the source Analysis Services instance specified in the **Source Folder** column of the selected

row in **Locations**. The grid contains the following columns:

Cube

Displays the name of the cube that contains the partition.

Measure Group

Displays the name of the measure group in the cube that contains the partition.

Partition Name

Displays the name of the partition.

Size(Mb)

Displays the size in megabytes (MB) of the partition.

6. Specify whether user permission information should be included, and whether compression should be used. By default, the wizard compresses all data and metadata prior to copying the files to the destination server. This option results in a faster file transmission. Files are uncompressed once they reach the destination server.

Copy all

Select to include security definitions and membership information during synchronization.

Skip membership

Select to include security definitions, but exclude membership information, during synchronization.

Ignore all

Select to ignore the security definition and membership information currently in the source database. If a destination database is created during synchronization, no security definitions or membership information will be copied. If the destination database already exists and has roles and memberships, that security information will be preserved.

7. Choose the synchronization method. You can synchronize immediately or generate a script that is saved to a file. By default, the file is saved with an .xmla extension and placed in your Documents folder.
8. Click **Finish** to synchronize. After verifying the options on the **Completing the Wizard** page, click **Finish** again.

Next Steps

If you did not synchronize roles or membership, remember to specify user access permissions now on the destination database.

[Deploy Model Solutions Using the Deployment Wizard](#)

Switch an Analysis Services database between ReadOnly and ReadWrite modes

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Analysis Services database administrators can change the read/write mode of a Tabular or Multidimensional database as part of larger effort that distributes a query workload among multiple query-only servers.

A database mode can be switched in several ways. This document explains the following common scenarios:

- Interactively using SQL Server Management Studio
- Programmatically using AMO
- Script using XMLA or TMSL

Switch the read/write mode of a database interactively using Management Studio

1. In Object Explorer, right-click the database and select **Properties**.

Note the location. An empty database storage location indicates that the database folder is located in the server data folder.

2. Right-click the database and select **Detach...**
3. Assign a password to the database to be detached, and then click **OK** to execute the detach command.
4. In Object Explorer, right-click the **Databases** folder and select **Attach...**
5. In the **Folder** text box, type the original location of the database folder. Alternatively, you can use the browse button (...) to locate the database folder.
6. Select the read/write mode for the database.
7. Type the password and click **OK** to execute the attach command.

Switch the read/write mode to a database programmatically using AMO

In your C# application, invoke `SwitchReadWrite()` with the necessary parameters. Compile and execute your code to move the database.

```

private void SwitchReadWrite(Server server, string dbName, ReadWriteMode dbReadWriteMode)
{
    if (server.Databases.ContainsName(dbName))
    {
        Database db;
        string databaseLocation;
        db = server.Databases[dbName];
        databaseLocation = db.DbStorageLocation;

        if (databaseLocation == null)
        {
            string dataDir = server.ServerProperties["DataDir"].Value;
            string dataDir = server.ServerProperties["DataDir"].Value;
            string dataDir = server.ServerProperties["DataDir"].Value;

            String[] possibleFolders = Directory.GetDirectories(dataDir, string.Concat(dbName,"*"),
SearchOption.TopDirectoryOnly);

            if (possibleFolders.Length > 1)
            {
                List<String> sortedFolders = new List<string>(possibleFolders.Length);
                sortedFolders.AddRange(possibleFolders);
                sortedFolders.Sort();
                databaseLocation = sortedFolders[sortedFolders.Count - 1];
            }
            else
            {
                databaseLocation = possibleFolders[0];
            }
        }
        db.Detach();
        server.Attach(databaseLocation, dbReadWriteMode);
    }
}

```

Switch the read/write mode to a database by script using XMLA

The following instructions apply to Multidimensional databases and Tabular databases at compatibility mode 1050, 1100, or 1103.

1. In Object Explorer, right-click the database and select **Properties**.

Note the location. An empty database storage location indicates that the database folder is located in the server data folder.

2. Right-click the database and select **Detach...**
3. Open a new XMLA tab in Management Studio.
4. Copy the following script template for XMLA:

```

<Detach xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Object>
    <DatabaseID>%dbName%</DatabaseID>
    <Password>%password%</Password>
  </Object>
</Detach>

```

5. Replace `%dbName%` with the name of the database and `%password%` with the password. The % characters are part of the template and must be removed.

6. Execute the XMLA command.
7. Copy the following script template for XMLA in a new XMLA tab

```
<Attach xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Folder>%dbFolder%</Folder>
  <ReadWriteMode xmlns="http://schemas.microsoft.com/analysisservices/2008/engine/100">%ReadOnlyMode%
  </ReadWriteMode>
</Attach>
```

8. Replace `%dbFolder%` with the complete UNC path of the database folder, `%ReadOnlyMode%` with the corresponding value **ReadOnly** or **ReadWrite**, and `%password%` with the password. The % characters are part of the template and must be removed.
9. Execute the XMLA command.

Processing a multidimensional model (Analysis Services)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Processing is the step, or series of steps, in which Analysis Services loads data from a relational data source into a multidimensional model. For objects that use MOLAP storage, data is saved on disk in the database file folder. For ROLAP storage, processing occurs on demand, in response to an MDX query on an object. For objects that use ROLAP storage, processing refers to updating the cache before returning query results.

By default, processing occurs when you deploy a solution to the server. You can also process all or part of a solution, either ad hoc using tools such as Management Studio or Visual Studio with Analysis Services projects, or on a schedule using Integration Services and SQL Server Agent. When making a structural change to the model, such as removing a dimension or changing its compatibility level, you will need to process again to synchronize the physical and logical aspects of the model.

This topic includes the following sections:

[Prerequisites](#)

[Choosing a tool or approach](#)

[Processing Objects](#)

[Reprocessing Objects](#)

Prerequisites

- Processing requires administrative permissions on the Analysis Services instance. If you are processing interactively from Visual Studio with Analysis Services projects or Management Studio, you must be a member of the server administrator role on the Analysis Services instance. For processing that runs unattended, for example using an SSIS package that you schedule through SQL Server Agent, the account used to run the package must be a member of the server administrator role. For more information about setting administrator permissions, see [Grant server admin rights to an Analysis Services instance](#).
- The account used to retrieve data is specified in the data source object, either as an impersonation option if you are using Windows authentication, or as the user name on the connection string if using database authentication. The account must have read permissions on relational data sources used by the model.
- The project or solution must be deployed before you can process any objects.

Initially, during the early stages of model development, deployment and processing occur together. However, you can set options to process the model later, after you deploy the solution. For more information about deployment, see [Deploy Analysis Services Projects \(SSDT\)](#).

Choosing a tool or approach

You can process objects interactively using a client application such as Visual Studio with Analysis Services projects or Management Studio, or a scripted operation that runs as a SQL Server Agent job or SSIS package.

How you process a database varies considerably depending on whether the model is in active development or in production. Once a model is deployed to a production server, processing must be tightly controlled to ensure the integrity and availability of multidimensional data. Because objects are interdependent, processing typically has a cascading effect across the model as other objects are also processed or unprocessed in tandem. If some objects are left in an unprocessed state, queries for that data will not resolve, breaking any reports or applications that use it. When developing a strategy for processing a production database, consider using script or SSIS packages that you have debugged and tested to avoid operator error or overlooked steps.

For more information, see [Tools and Approaches for Processing \(Analysis Services\)](#).

Processing Objects

Processing affects the following Analysis Services objects: measure groups, partitions, dimensions, cubes, mining models, mining structures, and databases. When an object contains one or more objects, processing the highest-level object causes a cascade of processing all the lower-level objects. For example, a cube typically contains one or more measure groups (each of which contains one or more partitions) and dimensions. Processing a cube causes processing of all the measure groups within the cube and the constituent dimensions that are currently in an unprocessed state. For more information about processing Analysis Services objects, see [Processing Analysis Services Objects](#).

While the processing job is working, the affected Analysis Services objects can be accessed for querying. The processing job works inside a transaction and the transaction can be committed or rolled back. If the processing job fails, the transaction is rolled back. If the processing job succeeds, an exclusive lock is put on the object when changes are being committed, which means the object is temporarily unavailable for query or processing. During the commit phase of the transaction, queries can still be sent to the object, but they will be queued until the commit is completed.

During a processing job, whether an object is processed, and how it will be processed, depends on the processing option that is set for that object. For more information about the specific processing options that can be applied to each object, see [Processing Options and Settings \(Analysis Services\)](#).

Reprocessing Objects

Cubes that contain unprocessed elements have to be reprocessed before they can be browsed. Cubes in Analysis Services contain measure groups and partitions that must be processed before the cube can be queried. Processing a cube causes Analysis Services to process constituent dimensions of the cube if those dimensions are in an unprocessed state. After an object has been processed the first time, it must be reprocessed either partially or in full whenever one of the following situations occurs:

- The structure of the object changes, such as dropping a column in a fact table.
- The aggregation design for the object changes.
- The data in the object needs to be updated.

When you process objects in Analysis Services, you can select a processing option, or you can enable Analysis Services to determine the appropriate type of processing. The processing methods made available differ from one object to another, and are based on the type of object. Additionally, the methods available are based on what changes have occurred to the object since it was last processed. If you enable Analysis Services to automatically select a processing method, it will use the method that returns the object to a fully processed state in the least time. For more information, see [Processing Options and Settings \(Analysis Services\)](#).

[Logical Architecture \(Analysis Services - Multidimensional Data\)](#)

Processing Options and Settings (Analysis Services)

7/16/2019 • 7 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

When you process objects in Microsoft SQL Server Analysis Services, you can select a processing option to control the type of processing that occurs for each object. Processing types differ from one object to another, and by changes that have occurred to the object since it was last processed. If you enable Analysis Services to automatically select a processing method, it will use the method that returns the object to a fully processed state in the least time.

Processing settings let you control the objects that are processed, and the methods that are used to process those objects. Some processing settings are primarily used for batch processing jobs. For more information about batch processing, see [Batch Processing \(Analysis Services\)](#).

NOTE

This topic applies to multidimensional and data mining solutions. For information about tabular solutions, see [Process Database, Table, or Partition \(Analysis Services\)](#).

Processing Options

The following table describes the processing methods that are available in Analysis Services, and identifies the objects for which each method is supported.

MODE	APPLIES TO	DESCRIPTION
Process Default	Cubes, databases, dimensions, measure groups, mining models, mining structures, and partitions.	Detects the process state of database objects, and performs processing necessary to deliver unprocessed or partially processed objects to a fully processed state. If you change a data binding, Process Default will do a Process Full on the affected object.
Process Full	Cubes, databases, dimensions, measure groups, mining models, mining structures, and partitions.	Processes an Analysis Services object and all the objects that it contains. When Process Full is executed against an object that has already been processed, Analysis Services drops all data in the object, and then processes the object. This kind of processing is required when a structural change has been made to an object, for example, when an attribute hierarchy is added, deleted, or renamed.
Process Clear	Cubes, databases, dimensions, measure groups, mining models, mining structures, and partitions.	Drops the data in the object specified and any lower-level constituent objects. After the data is dropped, it is not reloaded.

MODE	APPLIES TO	DESCRIPTION
Process Data	Dimensions, cubes, measure groups, and partitions.	Processes data only without building aggregations or indexes. If there is data in the partitions, it will be dropped before re-populating the partition with source data.
Process Add	Dimensions, measure groups, and partitions Note: Process Add is not available for dimension processing in Management Studio, but you can write XMLA script performs this action.	For dimensions, adds new members and updates dimension attribute captions and descriptions. For measure groups and partitions, adds newly available fact data and process only to the relevant partitions.
Process Update	Dimensions	Forces a re-read of data and an update of dimension attributes. Flexible aggregations and indexes on related partitions will be dropped.
Process Index	Cubes, dimensions, measure groups, and partitions	Creates or rebuilds indexes and aggregations for all processed partitions. For unprocessed objects, this option generates an error. Processing with this option is needed if you turn off Lazy Processing.
Process Structure	Cubes and mining structures	If the cube is unprocessed, Analysis Services will process, if it is necessary, all the cube's dimensions. After that, Analysis Services will create only cube definitions. If this option is applied to a mining structure, it populates the mining structure with source data. The difference between this option and the Process Full option is that this option does not iterate the processing down to the mining models themselves.
Process Clear Structure	Mining structures	Removes all training data from a mining structure.

Processing Settings

The following table describes the processing settings that are available for use when you create a process operation.

PROCESSING OPTION	DESCRIPTION	OPTION VALUE
-------------------	-------------	--------------

PROCESSING OPTION	DESCRIPTION	OPTION VALUE
Parallel	Used for batch processing. This setting causes Analysis Services to fork off processing tasks to run in parallel inside a single transaction. If there is a failure, the result is a roll-back of all changes. You can set the maximum number of parallel tasks explicitly, or let the server decide the optimal distribution. The Parallel option is useful for speeding up processing.	
Sequential (Transaction Mode)	<p>Controls the execution behavior of the processing job. Two options are available.</p> <p>When you process using One Transaction, all changes are committed after the processing job succeeds. This means that all Analysis Services objects affected by a particular processing job remain available for queries until the commit process. This makes the objects temporarily unavailable. Using Separate Transactions causes all objects that are affected by a process in processing job to be taken unavailable for queries as soon as that process succeeds.</p>	<p>One Transaction. The processing job runs as a transaction. If all processes inside the processing job succeed, all changes by the processing job are committed. If one process fails, all changes by the processing job are rolled back. One Transaction is the default value.</p> <p>Separate Transactions. Each process in the processing job runs as a stand-alone job. If one process fails, only that process is rolled back and the processing job continues. Each job commits all process changes at the end of the job.</p>
Writeback Table Option	Controls how writeback tables are handled during processing. This option applies to writeback partitions in a cube.	<p>Use Existing. Uses the existing writeback table. This is default value.</p> <p>Create. Creates a new writeback table and causes the process to fail if one already exists.</p> <p>Create Always. Creates a new writeback table even if one already exists. An existing table is deleted and replaced.</p>

PROCESSING OPTION	DESCRIPTION	OPTION VALUE
Process Affected Objects	<p>Controls the object scope of the processing job. An affected object is defined by object dependency. For example, partitions are dependent on the dimensions that determine aggregation, but dimensions are not dependent on partitions. False is the default setting.</p>	<p>False. The job processes the objects explicitly named in the job and all dependent objects. For example, if the processing job contains only dimensions, Analysis Services processes just those objects explicitly identified in the job. If the processing job contains partitions, partition processing automatically invokes processing of affected dimensions.</p> <p>True. The job processes the objects explicitly named in the job, all dependent objects, and all objects affected by the objects being processed without changing the state of the affected objects. For example, if the processing job contains only dimensions, Analysis Services also processes all partitions affected by the dimension processing for partitions that are currently in a processed state. Affected partitions that are currently in an unprocessed state are not processed. However, because partitions are dependent on dimensions, if the processing job contains only partitions, partition processing automatically invokes processing of affected dimensions, even when the dimension is currently in an unprocessed state.</p>
Dimension Key Errors	<p>Determines the action taken by Analysis Services when errors occur during processing. When you select Use custom error configuration, you can select values for the following actions to control error-handling behavior:</p> <p>When you select Use default error configuration, Analysis Services uses the error configuration that is set for each object being processed. If an object is set to use default configuration settings, Analysis Services uses the default settings that are listed for each option.</p>	
	<p>Key error action. If a key value does not yet exist in a record, one of these actions is selected to occur:</p>	<p>Convert to unknown. The key is interpreted as an unknown member. This is the default setting.</p> <p>Discard record. The record is discarded.</p>

PROCESSING OPTION	DESCRIPTION	OPTION VALUE
	<p>Processing error limit. Controls the number of errors processed by selecting one of these options:</p>	<p>Ignore errors count. This will enable processing to continue regardless of the number of errors.</p> <p>Stop on error. With this option, you control two additional settings. Number of errors lets you limit processing to the occurrence of a specific number of errors. On error action lets you determine the action when Number of errors is reached. You can select Stop processing, which causes the processing job to fail and roll back any changes, or Stop logging, which enables processing to continue without logging errors. Stop on error is the default setting with Number of errors set to 0 and On error action set to Stop processing.</p>
	<p>The following error conditions. You can set the option value to control specific error-handling behavior.</p> <p>When you select Use default error configuration, Analysis Services uses the error configuration that is set for each object being processed. If an object is set to use default configuration settings, Analysis Services uses the default settings that are listed for each option.</p>	<p>Key not found. Occurs when a key value exists in a partition but does not exist in the corresponding dimension. The default setting is Report and continue. Other settings are Ignore error and Report and stop.</p> <p>Duplicate key. Occurs when more than one key value exists in a dimension. The default setting is Ignore error. Other settings are Report and continue and Report and stop.</p> <p>Null key converted to unknown. Occurs when a key value is null and the Key error action is set to Convert to unknown. The default setting is Ignore error. Other settings are Report and continue and Report and stop.</p> <p>Null key not allowed. Occurs when Key error action is set to Discard record. The default setting is Report and continue. Other settings are Ignore error and Report and stop.</p>

Processing Analysis Services Objects

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Processing affects the following Microsoft SQL Server Analysis Services object types: Analysis Services databases, cubes, dimensions, measure groups, partitions, and data mining structures and models. For each object, you can specify the level of processing for the object, or you can specify the Process Default option to enable Analysis Services to automatically select the optimal level of processing. For more information about the different levels of processing for each object, see [Processing Options and Settings \(Analysis Services\)](#).

You should be aware of the consequences of processing behavior in order to reduce the occurrence of negative repercussions. For example, fully processing a dimension automatically sets all partitions dependent on that dimension to an unprocessed state. This causes affected cubes to become unavailable for query until the dependent partitions are processed.

This topic includes the following sections:

[Processing a Database](#)

[Processing a Dimension](#)

[Processing a Cube](#)

[Processing a Measure Group](#)

[Processing a Partition](#)

[Processing Data Mining Structures and Models](#)

Processing a Database

In Analysis Services, a database contains objects but not data. When you process a database, you direct the server to recursively process those objects that store data in the model, such as dimensions, partitions, mining structures, and mining models.

When you process a database, some or all partitions, dimensions, and mining models that the database contains are processed. The actual processing type varies depending on the state of each object and the processing option that you select. For more information, see [Processing Options and Settings \(Analysis Services\)](#).

Processing a Cube

A cube can be thought of as a wrapper object for measure groups and partitions. A cube is made of dimensions in addition to one or more measures, which are stored in partitions. Dimensions define how data is laid out in the cube. When you process a cube, an SQL query is issued to retrieve values from the fact table to populate each member in the cube with appropriate measure values. For any specific path to a node in the cube, there is a value or a calculable value.

When you process a cube, Analysis Services processes any unprocessed dimensions in the cube, and some or all partitions within the measure groups in the cube. The specifics depend on the state of the objects when processing starts and the processing option that you select. For more information about processing options, see [Processing Options and Settings \(Analysis Services\)](#).

Processing a cube creates machine-readable files that store relevant fact data. If there are aggregations created,

they are stored in aggregation data files. The cube is then available for browsing from the Object Explorer in Management Studio or Solution Explorer in Visual Studio with Analysis Services projects.

Processing a Dimension

When you process a dimension, Analysis Services formulates and runs queries against dimension tables to return information that is required for processing.

COUNTRY	SALES REGION	STATE
United States	West	California
United States	West	Oregon
United States	West	Washington

The processing itself turns the tabular data into usable hierarchies. These hierarchies are fully articulated member names that are internally represented by unique numeric paths. The following example is a text representation of a hierarchy.

[United States]
[United States].[West]
[United States].[West].[California]
[United States].[West].[Oregon]
[United States].[West].[Washington]

Dimension processing does not create or update calculated members, which are defined at the cube level. Calculated members are affected when the cube definition is updated. Also, dimension processing does not create or update aggregations. However, dimension processing can cause aggregations to be dropped. Aggregations are created or updated only during partition processing.

When you process a dimension, be aware that the dimension might be used in several cubes. When you process the dimension, those cubes are marked as unprocessed and become unavailable for queries. To process both the dimension and the related cubes at the same time, use the batch processing settings. For more information, see [Batch Processing \(Analysis Services\)](#).

Processing a Measure Group

When you process a measure group, Analysis Services processes some or all partitions within the measure group, and any unprocessed dimensions that participate in the measure group. Specifics of the processing job depend on the processing option that you select. You can process one or more measure groups in Analysis Services without affecting other measure groups in a cube.

NOTE

You can process individual measure groups programmatically, or by using Management Studio. You cannot process individual measure groups in Visual Studio with Analysis Services projects; however, you can process by partition.

Processing a Partition

Effective administration of Analysis Services involves the practice of partitioning data. Partition processing is unique because it involves consideration of hard disk use and space constraints, combined with data structure limitations imposed by Analysis Services. To keep query response times fast and processing throughput high, you have to regularly create, process, and merge partitions. It is very important to recognize and manage against the chance of integrating redundant data during partition merging. For more information, see [Merge Partitions in Analysis Services \(SSAS - Multidimensional\)](#).

When you process a partition, Analysis Services processes the partition and any unprocessed dimensions that exist in the partition, depending on the processing option that you select. Using partitions offers several advantages for processing. You can process a partition without affecting other partitions in a cube. Partitions are useful for storing data that is subject to cell writeback. Writeback is a feature that enables the user to perform what-if analysis by writing new data back into the partition to see the effect of projected changes. A writeback partition is required if you use the cell writeback feature of Analysis Services. Processing partitions in parallel is useful because Analysis Services uses the processing power more efficiently and can significantly reduce total processing time. You can also process partitions sequentially.

Processing Data Mining Structures and Models

A mining structure defines the data domain from which data-mining models will be built. One mining structure can contain more than one mining model. You can process a mining structure separately from its associated mining models. When you process a mining structure separately, it is populated with the training data from your data source.

When a data mining model is processed, the training data passes through the mining model algorithms, trains the model using the data mining algorithm, and builds the content. For more information about the data mining model object, see [Mining Structures \(Analysis Services - Data Mining\)](#).

For more information about processing mining structures and models, see [Processing Requirements and Considerations \(Data Mining\)](#).

Tools and Approaches for Processing (Analysis Services)

7/16/2019 • 5 minutes to read • [Edit Online](#)

APPLIES TO:  SQL Server Analysis Services  Azure Analysis Services  Power BI Premium

Processing is an operation in which Analysis Services queries a relational data source and populates Analysis Services objects using that data.

As an Analysis Services system administrator, you can execute and monitor the processing of Analysis Services objects using these approaches:

- Run Impact Analysis to understand object dependencies and scope of operations
- Process individual objects in SQL Server Management Studio
- Process individual or multiple objects in Visual Studio with Analysis Services projects
- Run Impact Analysis to review a list of related objects that will be unprocessed as result of the current action.
- Generate and run a script in an Analysis Services XMLA Query window in Management Studio to process individual or multiple objects
- Use Analysis Services PowerShell cmdlets
- Use control flows and tasks in SSIS packages
- Monitor processing with SQL Server Profiler
- Program a custom solution using AMO. For more information, see [Programming AMO OLAP Basic Objects](#).

Processing is a highly configurable operation, controlled by a set of processing options that determine whether full or incremental processing occurs at the object level. For more information about processing options and objects, see [Processing Options and Settings \(Analysis Services\)](#) and [Processing Analysis Services Objects](#).

NOTE

This topic describes the tools and approaches for processing multidimensional models. For more information about processing tabular models, see [Process Database, Table, or Partition \(Analysis Services\)](#).

Processing objects in SQL Server Management Studio

1. Start Management Studio and connect to Analysis Services.
2. Right-click the Analysis Services object you want to process and then click **Process**. You can process data at any of these levels:
 - Databases
 - Cubes
 - Measure Groups or individual partitions in the measure group
 - Dimensions

- Mining Models
- Mining Structures

Analysis Services objects are hierarchical. If you choose database, processing can occur for all of the objects contained in the database. Whether processing actually occurs will vary depending on the process option you select and the state of the object. Specifically, if an object is unprocessed, processing its parent will result in that object getting processed. For more information about object dependencies, see [Processing Analysis Services Objects](#).

3. In the **Process** dialog box, in **Process Options**, use the default value provided or select a different option from the list. For more information about each option, see [Processing Options and Settings \(Analysis Services\)](#).
4. Click **Impact Analysis** to identify and optionally process dependent objects that are affected if the objects listed in the Process dialog box are processed.
5. Optionally, click **Change Settings** to modify the processing order, processing behavior relative to specific types of errors, and other settings.
6. Click **OK**.

The Process Progress dialog box provides ongoing status for each command. If a status message is truncated, you can click **View Details** to read the entire message.

Processing Objects in SQL Server Data Tools

1. Start Visual Studio with Analysis Services projects and open a project that has been deployed.
2. In Solution Explorer, under the deployed project, expand the **Dimensions** folder.
3. Right-click a dimension, and then click **Process**. You can right-click multiple dimensions to process multiple objects at once. For more information, see [Batch Processing \(Analysis Services\)](#).
4. In the **Process Dimension** dialog box, in the **Process Options** column under **Object list**, verify that the option for this column is **Process Full**. If it is not, under **Process Options**, click the option, and select **Process Full** from the drop-down list.
5. Click **Run**.
6. When processing is finished, click **Close**.

Run Impact Analysis to identify object dependencies and scope of operations

1. Before you process an Analysis Services object in either Visual Studio with Analysis Services projects or Management Studio, you can analyze the effect on related objects by clicking **Impact Analysis** in one of the **Process Objects** dialog boxes.
2. Right-click a dimension, cube, measure group, or partition to open a **Process Objects** dialog box.
3. Click **Impact Analysis**. Analysis Services scans the model and reports on reprocessing requirements for objects that are related to the one you selected for processing.

Processing objects using XMLA

1. Start Management Studio and connect to Analysis Services.
2. Right-click the object to be processed and then click **Process**.
3. In the **Process** dialog box, select the process option you want to use. Modify any other settings. Run Impact

Analysis to identify any changes you might need to make.

4. Click **Script** on the **Process Objects** screen.

This generates an XMLA script and opens an Analysis Services XMLA Query window.

5. Close the dialog box. The script contains the processing command and options that were specified in the dialog box.
6. Optionally, you can continue adding to the script if you want to process additional objects in the same batch. To continue, repeat the previous steps, appending the generated script so that you have a single script for all processing operations. To view an example, see [Schedule SSAS Administrative Tasks with SQL Server Agent](#).

7. From the menu bar, click **Query**, and then click **Execute**.

Processing objects using PowerShell

Starting in this release of SQL Server, you can use Analysis Services PowerShell cmdlets to process objects.

Monitoring object processing using SQL Server Profiler

1. Connect to an Analysis Services instance in SQL Server Profiler.
2. In Events Selection, click **Show all events** to add all events to the list.
3. Choose the following events:
 - **Command Begin** and **Command End** to show when processing starts and stops
 - **Error** to capture any errors
 - **Progress Report Begin**, **Progress Report Current**, and **Progress Report End** to report on process status and show the SQL queries used to retrieve the data
 - **Execute MDX Script Begin** and **Execute MDX Script End** to show the cube calculations
 - Optionally, add lock events if you are diagnosing performance problems related to processing

Process Analysis Services objects using Integration Services

1. In Integration Services, create a package that uses the Analysis Services Processing Task to automatically populate objects with new data when you make regular updates to your source relational database.
2. In the **SSIS Toolbox**, double-click **Analysis Services Processing** to add it to the package.
3. Edit the task to specify a connection to the database, which objects to process, and the process option. For more information about how to implement this task, see [Analysis Services Processing Task](#).

[Processing a multidimensional model \(Analysis Services\)](#)

Batch Processing (Analysis Services)

7/16/2019 • 2 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

In Analysis Services, you can use the Batch command to send multiple processing commands to the server in a single request. Batch processing gives you a way to control which objects are to be processed, and in what order. Also, a batch can run as a series of stand-alone jobs, or as a transaction in which the failure of one process causes a rollback of the complete batch.

Batch processing maximizes data availability by consolidating and reducing the amount of time taken to commit changes. When you fully process a dimension, any partition using that dimension is marked as unprocessed. As a result, cubes that contain the unprocessed partitions are unavailable for browsing. You can address this with a batch processing job by processing the dimensions together with the affected partitions. Running the batch processing job as a transaction makes sure that all objects included in the transaction remain available for queries until all processing is completed. As the transaction commits the changes, locks are put on the affected objects, making the objects temporarily unavailable, but overall the amount of time used to commit the changes is less than if you processed objects individually.

The procedures in this topic show the steps for fully processing dimensions and partitions. Batch processing can also include other processing options, such as incremental processing. For these procedures to work correctly, you should use an existing Analysis Services database that contains at least two dimensions and one partition.

This topic includes the following sections:

[Batch Processing in SQL Server Data Tools](#)

[Batch Processing using XMLA in Management Studio](#)

Batch Processing in SQL Server Data Tools

Before objects can be processed in Visual Studio with Analysis Services projects, the project that contains the objects must be deployed. For more information, see [Deploy Analysis Services Projects \(SSDT\)](#).

1. Open Visual Studio with Analysis Services projects.
2. Open a project that has been deployed.
3. In Solution Explorer, under the deployed project, expand the **Dimensions** folder.
4. Holding the Ctrl key, click each dimension listed in the **Dimensions** folder.
5. Right-click the selected dimensions, and then click **Process**.
6. Holding the Ctrl key, click each dimension listed in the **Object list**.
7. Right-click the selected dimensions and select **Process Full**.
8. To customize the batch process job, click **Change Settings**.
9. Under **Processing options**, mark the following settings:
 - **Processing Order** is set to **Sequential**, and **Transaction mode** is set to **One Transaction**.
 - **Writeback Table Option** is set to **Use existing**.
 - Under **Affected Objects**, select the **Process affected objects** check box.

10. Click the **Dimension key errors** tab. Verify that **Use default error configuration** is selected.
11. Click **OK** to close the **Change Settings** screen.
12. Click **Run** in the **Process Objects** screen to start the processing job.
13. When the **Status** box shows **Process succeeded**, click **Close**.
14. Click **Close** on the **Process Objects** screen.

Batch Processing using XMLA in Management Studio

You can create an XMLA script that performs batch processing. Start by generating an XMLA script in Management Studio for each object, and then combine them into a single XMLA Query that you run interactively or inside a scheduled task.

For step by step instructions, see [Example 2 in Schedule SSAS Administrative Tasks with SQL Server Agent](#)

See Also

[Processing a multidimensional model \(Analysis Services\)](#)

Remote Processing (Analysis Services)

7/16/2019 • 3 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

You can run scheduled or unattended processing on a remote Analysis Services instance, where the processing request originates from one computer but executes on another computer on the same network.

Prerequisites

- If you are running different versions of SQL Server on each computer, the client libraries must match the version of the Analysis Services instance that is processing the model.
- On the remote server, **Allow remote connections to this computer** must be enabled, and the account issuing the processing request must be listed as an allowed user.
- Windows firewall rules must be configured to allow inbound connections to Analysis Services. Verify you can connect to the remote Analysis Services instance using SQL Server Management Studio. See [Configure the Windows Firewall to Allow Analysis Services Access](#).
- Resolve any existing local processing errors before attempting remote processing. Verify that when the processing request is local, data can be successfully retrieved from the external relational data source. See [Set Impersonation Options \(SSAS - Multidimensional\)](#) for instructions on specifying credentials used to retrieve data.

On-demand remote processing

Analysis Services accepts processing requests from user or application accounts that have Analysis Services administrator permissions. If you are an administrator, verify that you can connect to the remote instance and process the database manually over the remote connection.

1. On the computer that will be used to schedule processing, start SQL Server Management Studio and connect to the remote Analysis Services instance.
2. Right-click the database, select **Process**, point to **Script** and choose **Script Action to New Query Window**. Commands used to invoke processing will appear in the query window.
3. Click **OK** to begin processing.

Successful completion of this task provides an XMLA query that you can embed in a scheduled job. It also confirms there are no connection problems.

Schedule remote processing using SQL Server Agent Service

By default, SQL Server Agent service runs under a virtual account, with network connections made using the machine account. To avoid having to give a machine account administrative rights on the remote Analysis Services instance, you should change the SQL Server Agent service account to run as a least-privilege domain user account.

Be sure to grant all of the necessary permissions, including giving the account **sysadmin** rights on the Database Engine instance providing the service.

Use the following links to set permissions:

- [Configure SQL Server Agent](#)

- [SQL Server Agent Components](#) suggests alternative fixed server roles if granting **sysadmin** permissions is not possible.

After account permissions are configured, continue with these steps.

Grant the SQL Server Agent account administrator permission on SSAS

1. Using Management Studio, connect to the remote Analysis Services instance.
2. Right-click the server name, click **Properties**, and then click **Security**.
3. Click **Add** to add the SQL Server Agent account.

Create the Job

1. In Management Studio, connect to the local Database Engine instance. SQL Server Agent is the last item in Object Explorer. If necessary, start the service.
2. Right-click **Jobs**, click **New Job** and then enter a name.
3. In Steps, click **New** and then enter a name.
4. In Type, choose **SQL Server Analysis Services Command**.
5. In Server, enter the name of the remote Analysis Services instance.
6. In Command, paste the XMLA command for processing the database. This is the XMLA script that you generated in the verification step for on-demand remote processing. Click **OK** to save the job.

Start SQL Server Profiler

1. On the remote computer, start SQL Server Profiler. Connect to the Analysis Services instance, and click **Run** to start the trace using the default events.

You will use SQL Server Profiler to monitor the processing events as they occur.

2. Optionally, you can set trace properties to send the trace to a file or table in a database.

Run the job

1. On the computer used to run the job, verify that the job can perform the basic operation. In Object Explorer, under SQL Server Agent, expand **Jobs**, right-click the job you just created, and click **Start Job at Step**. The job starts immediately. You can monitor progress in SQL Server Profiler.
2. As a final step, modify the job to run on a schedule that you define, adding any alerts or notifications necessary to administer the job. You might also want to refine the processing script, or create multiple steps in the job to process objects independently.

Error Configuration for Cube, Partition, and Dimension Processing

7/16/2019 • 12 minutes to read • [Edit Online](#)

APPLIES TO: SQL Server Analysis Services Azure Analysis Services Power BI Premium

Error configuration properties on cube, partition, or dimension objects determine how the server responds when data integrity errors occur during processing. Duplicate keys, missing keys, and null values in a key column typically trigger such errors, and while the record causing the error will not be added to the database, you can set properties that determine what happens next. By default, processing stops. However, during cube development, you might want processing to continue when errors occur so that you can test cube behaviors with imported data, even if it is incomplete.

This topic includes the following sections:

- [Execution order](#)
- [Default behaviors](#)
- [Error Configuration Properties](#)
- [Where to set Error Configuration properties](#)
- [Missing keys \(KeyNotFound\)](#)
- [Null foreign keys in a fact table \(KeyNotFound\)](#)
- [Null keys in a dimension](#)
- [Duplicate keys resulting inconsistent relationships \(KeyDuplicate\)](#)
- [Change the error limit or error limit action](#)
- [Set the error log path](#)
- [Next step](#)

Execution order

The server always executes **NullProcessing** rules before **ErrorConfiguration** rules for each record. This is important to understand because null processing properties that convert nulls to zeroes can subsequently introduce duplicate key errors when two or more error records have zero in a key column.

Default behaviors

By default, processing stops at the first error implicating a key column. This behavior is controlled by an error limit that specifies zero as the number of allowed errors and the Stop Processing directive that tells the server to stop processing when the error limit is reached.

Records triggering an error, due to null or missing or duplicate values, are either converted to the unknown member or discarded. Analysis Services will not import data that violates data integrity constraints.

- Conversion to unknown member occurs by default, due to the **ConvertToUnknown** setting for **KeyErrorAction**. Records allocated to unknown member are quarantined in the database as evidence of a problem that you might want to investigate after processing is finished.

Unknown members are excluded from query workloads, but they will be visible in some client applications if the **UnknownMember** is set to **Visible**.

If you want to track how many nulls were converted to the unknown member, you can modify the **NullKeyConvertedToUnknown** property to report these errors to the log or in the Processing window.

- Discard occurs when you manually set the **KeyErrorAction** property to **DiscardRecord**.

Through error configuration properties, you can determine how the server responds when an error occurs. Options include stop processing immediately, continue processing but stop logging, or continue both processing and logging of errors. Defaults vary based on the severity of the error.

The error count keeps track of how many errors occur. When you set an upper limit, server response changes when that limit is reached. By default, the server stops processing after the limit is reached. The default limit is 0, causing processing to stop on the first error that is counted.

High impact errors, such as a missing key or null value in a key field, should be addressed quickly. By default, these errors adhere to **ReportAndContinue** server behaviors, where the server catches the error, adds it to the error count, and then continues processing (except the error limit is zero, so processing stops immediately).

Other errors are generated but not counted or logged by default (this is the **IgnoreError** setting) because the error does not necessarily pose a data integrity problem.

Error counts are affected by null processing settings. For dimension attributes, null processing options determine how the server responds when null values are encountered. By default, nulls in a numeric column are converted to zeroes, while nulls in a string column are processed as blank strings. You can override **NullProcessing** properties to catch null values before they turn into **KeyNotFound** or **KeyDuplicate** errors. See [Null keys in a dimension](#) for details.

Errors are logged in the Process dialog box but not saved. You can specify a key error log file name to collect errors in a text file.

Error Configuration Properties

There are nine error configuration properties. Five are used to determine server response when a specific error occurs. The other four are scoped to error configuration workloads, such as how many errors to allow, what to do when that limit is reached, whether to collect errors in a log file.

Server response to specific errors

PROPERTY	DEFAULT	OTHER VALUES
CalculationError Occurs when initializing error configuration.	IgnoreError neither logs nor counts the error; processing continues as long as the error count is under the maximum limit.	ReportAndContinue logs and counts the error. ReportAndStop reports the error and stops processing immediately, regardless of the error limit.

PROPERTY	DEFAULT	OTHER VALUES
KeyNotFound	ReportAndContinue logs and counts the error.	ReportAndStop reports the error and stops processing immediately, regardless of the error limit. IgnoreError neither logs nor counts the error; processing continues as long as the error count is under the maximum limit. Records that trigger this error are converted to the unknown member by default, but you can change the KeyErrorAction property to discard them instead.
KeyDuplicate	IgnoreError neither logs nor counts the error; processing continues as long as the error count is under the maximum limit.	ReportAndContinue logs and counts the error. ReportAndStop reports the error and stops processing immediately, regardless of the error limit.
NullKeyNotAllowed	ReportAndContinue logs and counts the error.	ReportAndStop reports the error and stops processing immediately, regardless of the error limit. IgnoreError neither logs nor counts the error; processing continues as long as the error count is under the maximum limit. Records that trigger this error are converted to the unknown member by default, but you can set the KeyErrorAction property to discard them instead.
NullKeyConvertedToUnknown	IgnoreError neither logs nor counts the error; processing continues as long as the error count is under the maximum limit.	If you consider this error to be informational, keep the default. Otherwise, you can choose ReportAndContinue to report the error to the Processing window and count the error towards the error limit. ReportAndStop reports the error and stops processing immediately, regardless of the error limit.

General Properties

PROPERTY	VALUES
KeyErrorAction	This is the action taken by the server when a KeyNotFound error occurs. Valid responses to this error include ConvertToUnknown or DiscardRecord .

PROPERTY	VALUES
KeyLogFile	This is a user-defined filename that must have a .log file extension, located in a folder on which the service account has read-write permissions. This log file will only contain errors generated during processing. Use the Flight Recorder if you require more detailed information.
KeyLimit	This is the maximum number of data integrity errors that the server will allow before failing the processing. A value of -1 indicates that there is no limit. The default is 0, which means processing stops after the first error occurs. You can also set it to a whole number.
KeyLimitAction	This is the action taken by the server when the number of key errors has reached the upper limit. With Stop Processing , processing terminates immediately. With Stop Logging , processing continues but errors are no longer reported or counted.

Where to set Error Configuration properties

Use the property pages in either SQL Server Management Studio after the database is deployed, or in the model project in Visual Studio with Analysis Services projects. The same properties are found in both tools. You can also set error configuration properties in the msmdrsrv.ini file to change server defaults for error configuration, and in **Batch** and **Process** commands if processing runs as a scripted operation.

You can set error configuration on any object that can be processed as a standalone operation.

SQL Server Management Studio

1. In Object Explorer, right-click **Properties** one of these objects: dimension, cube, or partition.
2. In Properties, click **Error Configuration**.

SQL Server Data Tools

1. In Solution Explorer, double-click a dimension or cube. **ErrorConfiguration** appears in Properties in the pane below.
2. Alternatively, for a single dimension only, right-click the dimension in Solution Explorer, choose **Process**, and then choose **Change Settings** in the Process Dimension dialog box. Error configuration options appear on the Dimension Key Errors tab.

Missing keys (KeyNotFound)

Records with a missing key value cannot be added to the database, not even when errors are ignored or the error limit is unlimited.

The server produces the **KeyNotFound** error during partition processing, when a table in fact record contains a foreign key value, but the foreign key has no corresponding record in a related dimension table. This error also occurs when processing related or snowflaked dimension tables, where a record in one dimension specifies a foreign key that doesn't exist in the related dimension.

When a **KeyNotFound** error occurs, the offending record is allocated to the unknown member. This behavior is controlled through the **Key Action**, set to **ConvertToUnknown**, so that you can view the allocated records for further investigation.

Null foreign keys in a fact table (KeyNotFound)

By default, a null value in a foreign key column of a fact table is converted to zero. Assuming zero is not a valid foreign key value, the **KeyNotFound** error will be logged and counted towards the error limit that is zero by default.

To allow processing to continue, you can handle the null before it is converted and checked for errors. To do this, set **NullProcessing** to **Error**.

Set **NullProcessing** property on a measure

1. In SQL Server Data Tools, in Solution Explorer, double-click the cube to open it in Cube Designer.
2. Right-click a measure in the Measures pane and choose **Properties**.
3. In Properties, expand **Source** to view **NullProcessing** property. It is set to **Automatic** by default, which for OLAP items, converts nulls to zeroes for fields containing numeric data.
4. Change the value to **Error** to exclude any records having a null value, avoiding the null-to-numeric (zero) conversion. This modification lets you avoid duplicate key errors related to multiple records having zero in the key column, and also avoid **KeyNotFound** errors when a zero-valued foreign key has no primary key equivalent in a related dimension table.

Null keys in a dimension

To continue processing when null values are found in foreign keys in a snowflaked dimension, handle the null values first by setting **NullProcessing** on the **KeyColumn** of the dimension attribute. This discards or converts the record, before the **KeyNotFound** error can occur.

You have two options for handling nulls on dimension attribute:

- Set **NullProcessing=UnknownMember** to allocate records with null values to the unknown member. This produces the **NullKeyConvertedToUnknown** error, which is ignored by default.
- Set **NullProcessing=Error** to exclude records with null values. This produces the **NullKeyNotAllowed** error, which is logged and counts toward the key error limit. You can set error configuration property on **Null Key Not Allowed** to **IgnoreError** to allow processing to continue.

Set **NullProcessing** property on a dimension attribute

1. In SQL Server Data Tools, in Solution Explorer, double-click the dimension to open it in Dimension Designer.
2. Right-click an attribute in the Attributes pane and choose **Properties**.
3. In Properties, expand **KeyColumns** to view **NullProcessing** property. It is set to **Automatic** by default, which converts nulls to zeroes for fields containing numeric data. Change the value to either **Error** or **UnknownMember**.

This modification removes the underlying conditions that trigger **KeyNotFound** by either discarding or converting the record before it is checked for errors.

Depending on error configuration, either of these actions can result in an error that is reported and counted. You might need to adjust additional properties, such as setting **KeyNotFound** to **ReportAndContinue** or **KeyErrorLimit** to a non-zero value, to allow processing to continue when these errors are reported and counted.

Duplicate keys resulting inconsistent relationships (KeyDuplicate)

By default, the presence of a duplicate key does not stop processing, but the error is ignored and the duplicate record is excluded from the database.

To change this behavior, set **KeyDuplicate** to **ReportAndContinue** or **ReportAndStop** to report the error. You can then examine the error to determine potential flaws in dimension design.

Change the error limit or error limit action

You can raise the error limit to allow more errors through during processing. There is no guidance for raising the error limit; the appropriate value will vary depending on your scenario. Error limits are specified as **KeyErrorLimit** in **ErrorConfiguration** properties in Visual Studio with Analysis Services projects, or as **Number of Errors** in the Error Configuration tab for properties of dimensions, cubes, or measure groups in SQL Server Management Studio.

Once the error limit is reached, you can specify that processing stops or that logging stops. For example, suppose you set the action to **StopLogging** on an error limit of 100. On the 101st error, processing continues, but errors are no longer logged or counted. Error limit actions are specified as **KeyErrorLimitAction** in **ErrorConfiguration** properties in Visual Studio with Analysis Services projects, or as **On error action** in the Error Configuration tab for properties of dimensions, cubes, or measure groups in SQL Server Management Studio.

Set the error log path

You can specify a file to store key-related error messages that are reported during processing. By default, errors are visible during interactive processing in the Process window and then discarded when you close the window or session. The log will only contain error information related to keys, identical to the errors you see reported in the processing dialog boxes.

Errors will be logged to a text file and must have .log file extension. The file will be empty unless errors occur. By default, a file will be created in the DATA folder. You can specify another folder as long as the Analysis Services service account can write to that location.

Next step

Decide whether errors will stop processing or be ignored. Remember that only the error is ignored. The record that caused the error is not ignored; it is either discarded or converted to unknown member. Records that violate data integrity rules are never added to the database. By default, processing stops when the first error occurs, but you can change this by raising the error limit. In cube development, it can be useful to relax error configuration rules, allowing processing to continue, so that there is data to test with.

Decide whether to change default null processing behaviors. By default, nulls in a string column are processed as empty values, while nulls in a numeric column are processed as zero.

Troubleshoot the Analysis Services error "OLE DB error: OLE DB or ODBC error: Operation canceled; HY008"

10/22/2019 • 15 minutes to read • [Edit Online](#)

This article describes background troubleshooting information and specific steps for one error that can occur when you use SQL Server Analysis Services when you process multi-dimensional models.

NOTE

This article is derived from a blog posted on June 11, 2012, and might contain dated material.

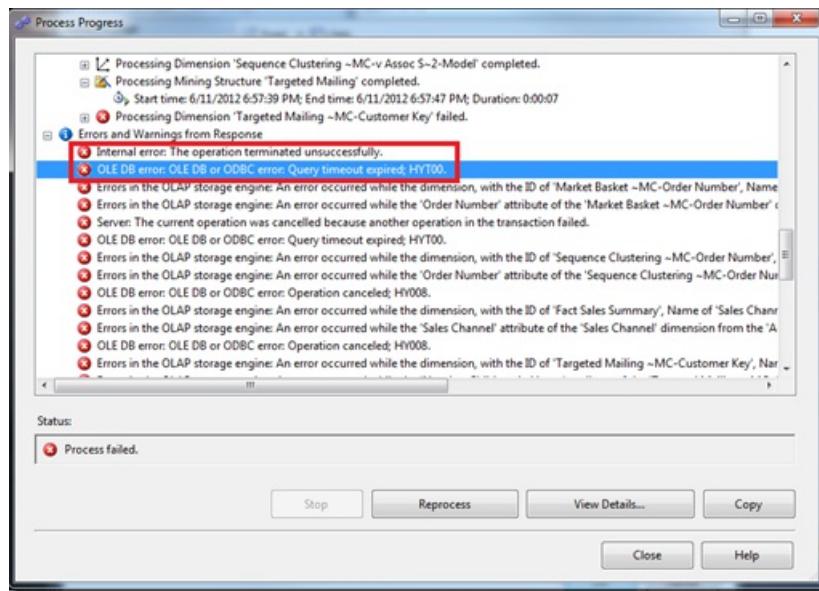

Errors during processing

Analysis Services processing might fail with this error:

OLE DB error: OLE DB or ODBC error: Operation canceled; HY008.

In SQL OLE DB terms, `HY008` means `DB_E_CANCELED`, which suggests that the query was canceled purposefully by the caller. At times, you can see this error better from SQL Server Management Studio:

```
Internal error: The operation terminated unsuccessfully.  
OLE DB error: OLE DB or ODBC error: Query timeout expired;HYT00.  
Errors in the OLAP storage engine: An error occurred while the dimension, with the ID of '<Some ID>', Name of '  
<Dimension Name>' was being processed.
```

`HYT00` means `DB_E_ABORTLIMITREACHED (0x80040E31)` or a timeout expired. The timeout expired due to the `SQL_QUERY_TIMEOUT` setting. The command timeout or query timeout kicked in to kill the running query and cancel the work.

XMLA equivalent command and errors

If you use XMLA commands to process your Analysis Services objects, the syntax might resemble the following example:

```

<Batch xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Parallel>
    <Process xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:ddl2="http://schemas.microsoft.com/analysisservices/2003/engine/2"
      xmlns:ddl2_2="http://schemas.microsoft.com/analysisservices/2003/engine/2/2"
      xmlns:ddl100_100="http://schemas.microsoft.com/analysisservices/2008/engine/100/100"
      xmlns:ddl200="http://schemas.microsoft.com/analysisservices/2010/engine/200"
      xmlns:ddl200_200="http://schemas.microsoft.com/analysisservices/2010/engine/200/200"
      xmlns:ddl300="http://schemas.microsoft.com/analysisservices/2011/engine/300"
      xmlns:ddl300_300="http://schemas.microsoft.com/analysisservices/2011/engine/300/300">
      <Object>
        <DatabaseID>AdventureWorksDW2012Multidimensional-EE</DatabaseID>
      </Object>
      <Type>ProcessFull</Type>
      <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
    </Process>
  </Parallel>
</Batch>

```

When a timeout occurs, the system shows a list of different errors appended in a long string. One or several of the database connections have a timeout, but you might not notice. There's significant noise in the error that the multiple connections get from a cancellation notification. Analysis Services reports the errors in a seemingly random order due to the multi-threaded nature of the processing implementation. The timeout indicator is hard to see.

```

Internal error: The operation terminated unsuccessfully. Internal error: The operation terminated unsuccessfully. Server: The current operation was cancelled because another operation in the transaction failed. Internal error: The operation terminated unsuccessfully. OLE DB error: OLE DB or ODBC error: **Communication link failure; 08S01; Shared Memory Provider: No process is on the other end of the pipe. ; 08S01.** Errors in the OLAP storage engine: An error occurred while the dimension, with the ID of 'Dim Time', Name of 'Date' was being processed. Errors in the OLAP storage engine: An error occurred while the 'Fiscal Year' attribute of the 'Date' dimension from the 'AdventureWorksDW2012Multidimensional-EE' database was being processed. OLE DB error: OLE DB or ODBC error: Communication link failure; 08S01; Shared Memory Provider: No process is on the other end of the pipe.

```

To understand this output, `08S01` means `DB_E_CANNOTCONNECT` from the provider. This HRESULT is a bit of a misnomer. It could be that the system can't connect or that it's been disconnected or canceled by the provider or the server if the query was canceled.

Check the `OLAP\Log\Msmdsrv.log` file. You might get the error message in case your application didn't log it.

```

(6/12/2012 4:52:21 PM) Message: (Source: [\\?\C:\OLAP\Log\msmdsrv.log](file://\\?\C:\OLAP\Log\msmdsrv.log), Type: 3, Category: 289, Event ID: 0xC1210003)

(6/12/2012 4:52:24 PM) Message: OLE DB error: OLE DB or ODBC error: Operation canceled; HY008. (Source: [\\?\C:\OLAP\Log\msmdsrv.log](file://\\?\C:\OLAP\Log\msmdsrv.log), Type: 3, Category: 289, Event ID: 0xC1210003)
(6/12/2012 4:45:33 AM) Message: OLE DB error: OLE DB or ODBC error: Operation canceled; HY008. (Source: [\\?\C:\OLAP\Log\msmdsrv.log](file://\\?\C:\OLAP\Log\msmdsrv.log), Type: 3, Category: 289, Event ID: 0xC1210003)

```

The preceding log output indicates that the OLE DB provider reported an error, hex code `0xC1210003`.

Attempt to simplify the error

If you're unable to determine which specific object and attribute are causing the problem, simplify the processing parallelism by restricting the number of connections to the relational database.

In **Solution Explorer**, select your **Data Source** properties. Adjust **Maximum number of connections** from a

value of 10 to a value of 1. The next time you process the objects, any failure might show the problem attributes better and a more exact error description.

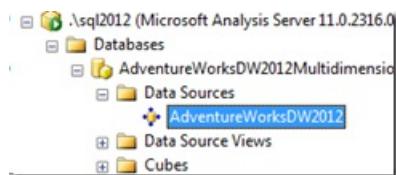

Background on cube processing

When Analysis Services processes a cube or a lower-level object like a dimension or measure group, it sends many large SQL queries to the relational database engine through an OLE DB provider. For example,

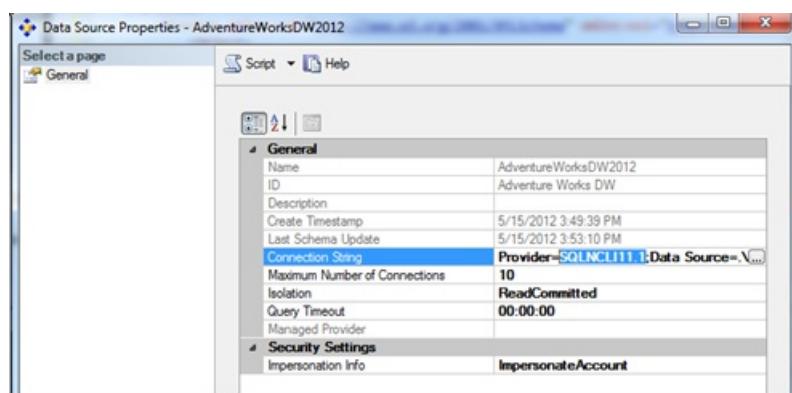

```
SELECT * FROM DimTable1, SELECT * FROM FactTable1 .
```

These processing queries can take from minutes to hours to run. The length of time depends on how many joins there are and how large the tables and partitions are. The number of joins is dependent entirely on your cube design, and your dimension and measure group relationships in the design.

To connect to the relational data source, there are connection strings stored in the cube design to point to the data warehouse in the database server.

This is a connection string that gets saved into the Analysis Services database design. It can point to SQL Server, or it can point to other third-party relational databases, such as Teradata and Oracle. In the following screenshot, the SQL Server 2012 OLE DB provider named **SQLNCLI11.1** is shown.

Background on command and connection timeouts

Whenever a command such as a T-SQL query in the case of SQL Server is issued to the data source, the command timeout property is set by the Analysis Services caller.

The following example shows ADO pseudo code to show how a command timeout is set by the code that runs Analysis Services internally:

```
conn1.Open();
command = conn1.CreateCommand();
command.CommandText = "Select * from DimTable";
command.CommandTimeout = 15;
```

In the preceding example, if 15 seconds pass and the query hasn't yet finished, the OLE DB provider cancels the query on behalf of the caller. The caller doesn't have to keep any timer because the timeout is set in the provider layer. But if the query fails, the caller doesn't really know how long it took and if it was a timeout or not.

In OLE DB terms, this property is called **DBPROP_COMMANDTIMEOUT** on the **DBPROPSET_ROWSET** object. This property lets you run queries for a certain amount of time. If the command doesn't finish, it's canceled.

In SQL Server, you can see such timeouts with an Attention event in the profiler trace. In that profiler trace, the event duration exactly matches the duration of the command timeout.

The command timeout setting isn't set on the connection or the connection string itself. It must be set after a connection is established, as each command object is used. There's a similar connection timeout,

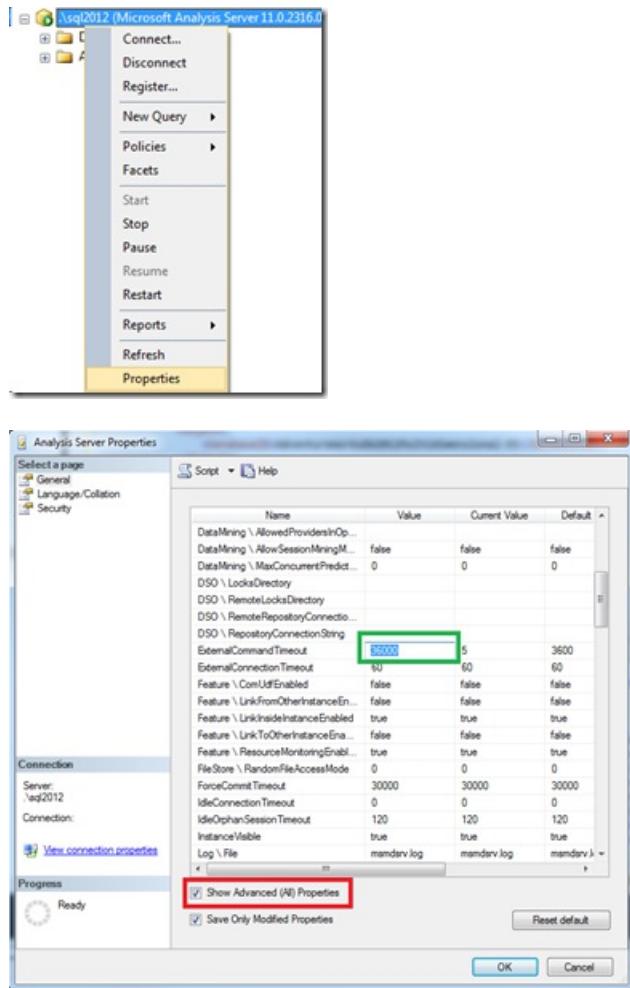

`DBPROP_INIT_TIMEOUT` on the `DBPROPSET_DBINIT` object. In Analysis Services, the connection timeout is the separate property **ExternalConnectionTimeout**. This setting is applicable for making initial contact with the server and checking the authentication and authorization of accounts. This setting doesn't affect long-running queries typically, because the initial connection was successful without failure.

You can control the OLE DB command timeout in Analysis Services. There's an **ExternalCommandTimeout** setting in the advanced options on the Analysis Services instance. The default value is 60 mins (one hour). That timeout value might not be long enough. This default configuration allows any one T-SQL query to the relational database to last one hour or more. After that point, the command is canceled by the OLE DB provider used to connect to that system, and the Analysis Services processing command fails.

The **ExternalCommandTimeout** integer property defines the timeout, in seconds, for commands issued to external servers, which includes relational data sources and external Analysis Services servers. The default value for this property is 3,600 seconds.

If you expect the processing queries to take more than one hour, raise the timeout higher than one hour. In one example, the processing join queries took around nine hours to complete on a 2-TB database with some large complex joins.

Right-click the server name in **Management Studio > Properties**. Select the **Show Advanced (All) Properties** check box. Then adjust the **ExternalCommandTimeout** setting, as shown in the following images:

Now when the server runs external queries to talk to the relational database, it sets the command timeout to the value specified so that it can run a long time without failure.

Long processing duration can lead to timeouts

If processing queries takes more than an hour, there might be ways to tune the system to perform faster:

- Tune the joins that Analysis Services does when it runs all those processing queries in the background on your behalf.
- Partition your measurement groups so that the unit of work done by processing is a smaller chunk of data rather than all the data at once. Partitioning requires careful thought and cube design work. If your data has more than 20 million rows in a table and you see processing performance problems, consider partitioning.

Tune the relational database system

After you run the cube processing once or twice, look for missing indexes in the relational database or data warehouse system. Take a few minutes to tune the database. Add some indexes to the relational data warehouse tables to help tune the join criteria to process the cube.

The following T-SQL code is borrowed from the support tool PSSDiag. It identifies the most helpful missing indexes and works on SQL Server 2005 and later. Find the indexes on the fact and dimension tables that help improve the performance the most. Remember that while adding an index might help read performance like cube processing, it might slow some insert and update performance, such as extract, transform, load (ETL) activities.

```
PRINT 'Missing Indexes: ' PRINT 'The "improvement_measure" column is an indicator of the (estimated) improvement that might ' PRINT 'be seen if the index was created. This is a unitless number, and has meaning only relative ' PRINT 'the same number for other indexes. The measure is a combination of the avg_total_user_cost, ' PRINT 'avg_user_impact, user_seeks, and user_scans columns in sys.dm_db_missing_index_group_stats.' PRINT '' PRINT '-- Missing Indexes --' SELECT CONVERT (varchar, getdate(), 126) AS runtime, mig.index_group_handle, mid.index_handle, CONVERT (decimal (28,1), migs.avg_total_user_cost * migs.avg_user_impact * (migs.user_seeks + migs.user_scans)) AS improvement_measure, 'CREATE INDEX missing_index_' + CONVERT (varchar, mig.index_group_handle) + '_' + CONVERT (varchar, mid.index_handle) + ' ON ' + mid.statement + ' (' + ISNULL (mid.equality_columns, '') + CASE WHEN mid.equality_columns IS NOT NULL AND mid.inequality_columns IS NOT NULL THEN ',' ELSE '' END + ISNULL (mid.inequality_columns, '') + ')' + ISNULL (' INCLUDE (' + mid.included_columns + ')', '') AS create_index_statement, migs.*, mid.database_id, mid.[object_id] FROM sys.dm_db_missing_index_groups mig INNER JOIN sys.dm_db_missing_index_group_stats migs ON migs.group_handle = mig.index_group_handle INNER JOIN sys.dm_db_missing_index_details mid ON mig.index_handle = mid.index_handle WHERE CONVERT (decimal (28,1), migs.avg_total_user_cost * migs.avg_user_impact * (migs.user_seeks + migs.user_scans)) > 10 ORDER BY migs.avg_total_user_cost * migs.avg_user_impact * (migs.user_seeks + migs.user_scans) DESC PRINT '' GO
```

Memory competition impact on timeouts

There are multiple reasons that timeouts might occur, and many include non-timeout scenarios. The second most common cause of a processing T-SQL query cancellation is out-of-memory failures.

There can be competition for memory between SQL Server Database Engine (SQLServr.exe), Analysis Services (MsMdsrv.exe), Integration Services packages (DTEexec.exe or ISServerExec.exe), and Reporting Services running on the same machine. You might need to throttle back the other services or balance memory allocations. The most common adjustment is to limit the SQL Server **maximum server memory** setting.

Cube processing is like the most intensive processing time for a SQL Server used as a data warehouse, because Analysis Services pushes several large queries with complex joins to the SQL relational database engine at the same time.

```
exec sp_configure 'show advanced',1;
reconfigure;
exec sp_configure 'min server memory';
exec sp_configure 'max server memory';
-- look at config_value in the results for the current MB setting configured
```

The ETL processes that typically run rarely benefit from the normal buffering of the SQL Server database engine's buffer pool. Consider SQL Server Integration Services (SSIS) packages that import large sets of data from a transactional system into a data warehouse system. ETL operations often use BULK INSERT commands that don't require much warm data in memory.

Other ETL operations during the ETL phase of building a data warehouse benefit from SQL's large buffer pool. The read (SELECT) and UPDATE and JOIN parts of the ETL processing, such as Lookups and slowly changing dimension updates, use cached warm data in memory, if available. Lowering the SQL Server Database Engine's memory might have a side effect on those parts of the ETL imports that usually go on just before cube processing.

Reading data from RAM is 1000-1million times faster than reading from your average spinning disk drive, so shrinking the SQL buffer pool means more disk reads. Unless you have high-end solid-state disks (SSDs) or a high-end SAN, you might wait a little more.

Measure memory consumption in the system

If memory is the culprit, gather a profiler trace and these performance counters to better investigate the cause:

1. Set up the Windows **Performance Monitor** to produce a trace of resource consumption. Select **Start > Run > Perfmon**.
2. Right-click the **Counter Logs** icon in the tree under **Performance Logs**, and begin a new counter log. Name the log.
3. Add the counter for the following objects: *all* counters for each object, and *all* instances for each object.
 - Memory
 - MSAS* --- all objects (for a default instance of Analysis Services)
 - MSOLAP\$InstanceName* --- all objects (for a named instance of Analysis Services)
 - MSSQL* --- all objects (for the SQL Server Database Engine)
 - Paging File
 - Process
 - Processor
 - System
 - Thread
4. Sample every 15 seconds.
5. On the **Log** tab, specify the directory and file name strategy as a **Binary File**.
6. To get the **Performance Monitor** to roll over to a new file once a day, on the **Schedule** tab, select:
 - **Stop log after: 1 day**
 - **When the log file closes: Start a new log file**

Review the Performance Monitor results

1. Look at the SQL Server engine's counter to see if **SQL Memory > Total Server Memory** was increasing out of control.
2. Look at the **Memory > Available MBytes** counter to see how much free memory was available to the processes running in Windows.
3. Look at **Process > Private Bytes** for the various executable processes to see how much each takes in comparison.
4. Look at the **MSAS** and **MSOLAP** counters. If the usage amount goes above the **High KB** amount, Analysis Services has to trim some of the buffers in memory.
 - **Memory Usage KB**

- **Memory Limit High KB**
- **Memory Limit Low KB**
- **Memory Limit Hard KB**

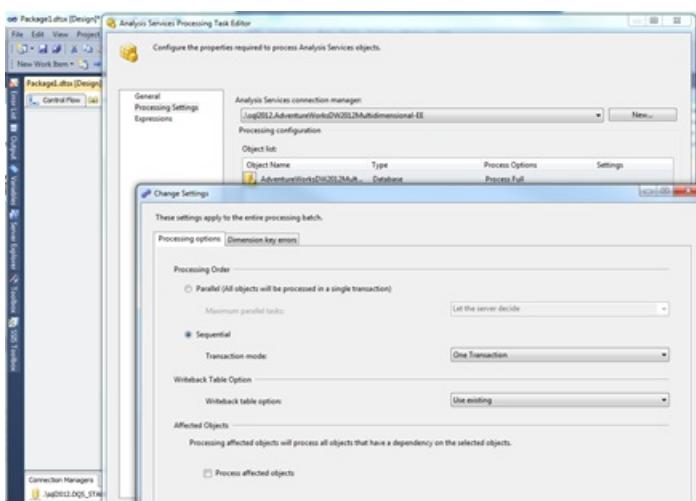

If the **Memory Usage KB** amount exceeds the **Hard KB** limit, Analysis Services might cancel all current work and go into *panic mode* to kill off the memory consumers. Panic mode might manifest itself in similar errors, but usually the error is more descriptive, such as **The Operation Has been Cancelled** or

The session was canceled because it exceeded a timeout setting (session orphaned timeout or session idle timeout) or it exceeded the session memory limit.
